[1] See *Die Thierarten des Aristoteles, von der Klassen der Säugethiere, Vögel, Reptilien, und Insecten*, von Carl J. Sundevall, Uebersetzung aus dem Schwedischen (Stockholm, 1863). Prof. Sundevall estimates the total number of mammals indicated and described by Aristotle to have been about 70; of birds, 150; of reptiles, 20; and of fishes, 116; making altogether 356 species of vertebrate animals. Of the invertebrate classes, about 60 species of insects and arachnids seem to have been known to Aristotle; some 24 crustaceans and annelids, and about 40 molluscs and radiates. See *The Natural History Review for* 1864, page 494.

[6] *Eth. Nic.*, viii. 1, 7, &c.

[7] This little treatise bears all the marks of being a monograph in which the conclusions out of various parts of Aristotle's physical, psychological, and metaphysical writings are amplified and brought together. Rose gives arguments to show that the physiology of this book, and of the treatise *On Breath*, belongs to a medical school (Praxagoras, Erasistratus, &c.) later than the time of Aristotle. He admits the *De Motu Animal.* to have been compiled by some very able Peripatetic, *De Ar. Lib. Ord. et Auct.*, pp. 162–174.

[10] See a critical examination of all the places in Zeller's *Platonische Studien* (Tubingen, 1839), pp. 199–300.

[11] Plato by no means consistently maintained the doctrine of Ideas, as commonly attributed to him. In the *Parmenides* he himself draws out the objections which may be urged against the system. And, wonderful to relate, Aristotle uses some of these very objections in attacking Plato!

[12] *Topics*, vi. 4, 1–10, and see note 13, p. 514.

(ἐνέργεια) into existence, and this could not be without implying the previous existence of the potential. The universe, according to Aristotle, is a continuous chain; at the one end is the purely potential—matter without form or qualities; at the other end is pure unconditioned actuality, the ever existent, or God.

Reflection upon the relations of the potential and the actual shows the world to have been eternal, for the actual must always have preceded the potential;[1] the seed is the potentiality of the plant, and the plant must always have preceded the seed,[2] the fowl the egg, &c. Thus, all the system of cause and effect, which makes up what is called "nature," has been and will be, according to Aristotle, of eternal duration, and is only slightly modified and altered by two uncalculable elements[3] of causation,—chance and the will of man.

"Nature," or the system prevailing from the earth upwards through the planetary sphere, is full of reason; it does nothing in vain.[4] The formal cause, the form, or perfection, of each thing, is generally to be identified with the final cause, or end, at which nature aims. Matter, rising from the merely potential, through the four elements into various substances, is the material cause; and the efficient, or motive cause is supplied by the active powers of heat and cold. Nature, however, is impersonal, and to speak of it as pervaded by reason, has all the appearance of pantheism. But yet in the system of Aristotle there was a God who was not part of nature. Aristotle's utterances on this subject are obscure; he speaks of the unmoved Mover of all things at one time[5] as if He supplied motion to the periphery of heaven, at another as if He moved things by desire, under the form of the Good. But, at all events, He is personal: He enjoys for ever that bliss which we can only at brief moments attain to; His life is the thinking upon thought. In all this there is something incomplete, and the different points of view are not reconciled. Aristotle argues that[6] God could not, as thought, have any object of thought inferior to himself, else the divine thought, by thinking upon an inferior object, would suffer change and degradation. God, therefore, can only think upon himself. This argument would seem to foreclose the possibility of either Providence or prayer. There is something Eastern in this idea of a God absorbed in self-meditation; and, on the other hand, we observe that Aristotle, while considering no trouble too great to obtain excellence in any little point of art, or science, or morals, or politics,—still, in comparison with the great universe, makes human affairs of relatively little importance. But yet, within the sphere of nature, man is, according to him, the highest product—indeed, the one end for which all the arrangements of nature are but means.[7] Nor does man himself fall wholly within the sphere of nature. Every natural soul is the ultimate expression (ἐντελέχεια) of a corresponding physical body. But in the human soul there is something which has no physical substratum, which came in from without.[8] And, if not physical, this something must belong to the ethereal essence of which the outer heavens and the self-conscious, happy stars are composed. Thus man, by his reason, has a direct connection with the sphere of the eternal and the blessed. The question then arises whether the individual man can look forward to immortality. On this, regardless of Plato's elaborate pictures of a Hell, a Purgatory, and a Heaven, Aristotle says nothing. In one celebrated passage[9] he makes reason twofold, the active and the passive, of which the active reason, and it alone, is indestructible; but if this be incapable of receiving impressions, it would seem that all our memory,—in short, all that constitutes human individuality,—is doomed to extinction. But Aristotle never says so in express terms, and therefore has given scope for much controversy in modern times as to his opinion.[10]

Returning to his psychology, we find that[11] he considers knowledge to imply a certain similarity, if not identity, between the subject and the object. Therefore, the higher reason in apprehending universals, apprehends something homogeneous with itself,—something, in short, ethereal, This would bring the Aristotelian universals very near to the Platonic ideas, but that he maintains[12] that the universals are always immanent in the individuals, never transcendental, or existing by themselves. But this doctrine widely separates Aristotle from the modern experimental school, though, on the other hand, there is no trace of his having believed in "innate ideas" upon any subject. Aristotle, like Locke, considered each human mind to be originally a blank tablet, but he would not agree with Locke that this tablet is written upon by external objects, he would rather say that, by the joint action of the active and the passive reason, the tablet writes upon itself, and that there is much in our knowledge which comes from the nature of the intellect itself. Two doctrines lie at the foundation of his system: 1st, the principle of contradiction,—that a thing must be either A or not A; 2d, the dualistic opposition, throughout the universe, of reason and matter. In modern times we have been long accustomed to think of this world as having had a beginning, and recent theories of "development" are attempts at a speculative history of nature gradually arriving at its present condition. Such theories have nothing to correspond to them in the system of Aristotle, for in his view the present fabric of the world has had an eternal existence, and nature is fixed, being only slightly varied by the element of chance. He admits, indeed, a process of development in human society, but in order to adapt this process to a fixed and eternal frame of things he announces[13] the curious opinion, that the human race has repeatedly brought to perfection all art, science, and philosophy, and has on each occasion been swept away by some widespread catastrophe or convulsion of nature, leaving only a few individuals to repropagate the race, and to begin again the development of civilisation out of the merest rudiments.

In endeavouring to bring forward, in a brief space, some of the salient characteristics of Aristotle, we have been led to mention chiefly those points on which he differs most

---

[2] A similar doctrine to this was stated by Sir W. Thomson in his address to the British Association, 1871. He said, "I am ready to adopt as an article of scientific faith, true through all space and through all time, that *life proceeds from life, and from nothing but life.*" His suggestion as to our own globe was "that life originated on this earth through moss-grown fragments from the ruins of another world."

[10] Averroes made for himself a bad name by pushing the words of Aristotle to their logical conclusion. On the other hand, St Thomas Aquinas argued in favour of Aristotle's belief in immortality. Spengel, apparently, takes the latter view (see note 3, p. 520); he quotes with approval an anonymous ancient—*Ὅτι Πλάτων, φησί, καὶ Ἀριστοτέλης ἀθάνατον ὁμοίως λέγουσι τὴν ψυχήν, κἂν τινες εἰς τὸν Ἀριστοτέλους νοῦν οὐκ ἐμβαθύνοντες θνητὴν νομίζουσιν αὐτὸν λέγειν.* See some criticisms on Grote's view, *Ed. Rev.*, No. 278, pp. 553-556.

widely from the modern point of view, and which, therefore, are his points of weakness. Much that the world has accepted from him, many a solid mass of wisdom and good sense, to be found in his writings, we have been obliged to pass over in silence. On most subjects Aristotle is no longer an authority, but yet, for many reasons his works are well worth study. *First*, on account of the important part they have borne in the history of the world. No one who aspires to cultivation can dispense with a historical knowledge of the thought of Europe, and Aristotle is one of the great fountain-heads of that thought. *Secondly*, if cultivation consists, as has been said, in an acquaintance with all the best productions of the human mind, Aristotle's works, despite their want of style, certainly come among the number. Hegel advocated the study of these works as "the noblest problem of classical philology." The University of Oxford, during the present century, has made a renewed study of Aristotle one of its chief instruments of education,—and with great success, as was especially testified to by the late Dr Arnold[1] of Rugby. Aristotle's great knowledge of human nature, exhaustive classification, and clear methods of disentangling a question and dealing with what is essential in it, render many of his works an excellent *curriculum* for training young men, and fitting them for all the superior business of life. There is a certain dynamical impulse to be derived from Aristotle, independent of all his results and conclusions. The Aristotelian element in thought and knowledge may, perhaps, be summed up as "analytic insight;" and this insight arises out of concentration of the mind upon the subject in hand, marshalling together all the facts and opinions attainable upon it, and dwelling on these, and scrutinising and comparing them till a light flashes on the whole subject. Such is the procedure which may be learnt, by imitation, from Aristotle.

The history of the study of the Aristotelian philosophy, since the time of Andronicus, falls under various heads, dealt with elsewhere. It is contained,—*first*, under such names as those of the Greek commentators, Boethus, Nicolas Damascenus, Alexander of Ægæ, Aspasius, Adrastus, Galenus, Alexander of Aphrodisias, Porphyry, Iamblichus, Dexippus, Themistius, Proclus, Ammonius, Damascius, David the Armenian, Asclepius, Olympiodorus, Simplicius, and Johannes Philoponus; *secondly*, under the history of the caliphs of Baghdad, and their encouragement of the translation into Arabic of Greek philosophical works; *thirdly*, under the names of Avicenna (of Baghdad), and Averroes, and Moses Maimonides (of Cordova), and the history of the controversies to which they gave rise; *fourthly*, under the name of Thomas Aquinas, and the history of Scholasticism generally; *fifthly*, under the history of the Renaissance, and of the manifold editions of Aristotle to which the first age of printing gave birth; *sixthly*, under the names of Ramus and Bacon, and the history of the reaction against scholastic Aristotelianism; *seventhly*, under the names of Lessing, Hegel, and other great Germans who, within the last hundred years, have revived a genuinely philosophical and critical study of Aristotle.

For the bibliography of Aristotle's works we must refer to the first volume of Buhle's (Bipontine) edition (1791–1800), which contains an enumeration of all the earlier editions, translations, and commentaries. All previous editions of the text of the entire works give way to the recension of Immanuel Bekker (1831–1840), which being supplemented by a volume of *Scholia* upon Aristotle, edited by Brandis (1836), and a complete index to all the works, compiled by Bonitz (1870), constitutes the great edition of the Prussian Royal Academy. Within the last forty years much admirable work has been done in Germany in the way of clearing up special questions relating to Aristotle, and introducing correct judgments about his philosophy generally. Perhaps the scholar who, by a mixture of rich learning and penetrating good sense, has deserved best of Aristotle is Dr Leonhard Spengel, to whose papers, contributed to the Royal Bavarian Academy of Munich, we have often previously referred. The historians of philosophy, beginning with Hegel's "Lectures," and going on to Brandis, Zeller, Schwegler, and Ueberweg, reflect the progressive opinions about Aristotle of critical and philosophical circles. Many excellent editions of the separate treatises, and many monographs on special points, have performed a subsidiary function. And a good German translation, executed by Stahr, Bender, Karsel, &c., of the works of Aristotle, now nearly complete, has been published at Stuttgart, by Krais and Hoffmann.

No other nation can compare with Germany in recent services towards a knowledge of Aristotle. France has contributed translations of the *Physics*, *De Anima*, *Parva Naturalia*, *Organon*, *Politics*, and *Ethics*, by Barthélemy St Hilaire, an essay on the *Metaphysics*, by Ravaisson, and a few less important works. The translations are readable, but cannot be relied on for accuracy in any difficult point. In England the contributions to Aristotelian literature have borne no sort of proportion to the extent to which minds have been educationally imbued with certain of Aristotle's works. The unproductiveness of Oxford in this respect is certainly a matter of reproach to that university. Sir W. Hamilton exhibited great learning in all that concerned Aristotle rather than a true insight into Aristotle himself. Grote's work was conceived in a German spirit, but it was begun far too late in life to have any chance of success. The problem how to translate Aristotle into English has not yet been solved. We have had a translation of the entire works by the not very sane, and very unscholarlike, Thomas Taylor (10 vols., London, 1806–12), which exists only as a curiosity for book collectors. And we have had the not uncreditable versions of Bohn's Classical Library, but these latter were done to order, and cannot be expected to perform what is in itself so difficult. Mr Poste, perhaps the most thorough of present English Aristotelians, in his *Aristotle on Fallacies*, gives us rather a condensed paraphrase than a translation, and is often as difficult as the original Greek. The problem is, how to convey, in readable English, a philosophical style, full of technical terms for which we have no exact representatives. Circumlocution, or paraphrase, becomes necessary; the question is, how to use this with the greatest tact, so as, while conveying Aristotle's exact meaning, to retain something of his manner. Perhaps this problem may, in course of time, be solved, if in the meanwhile the study of Greek is not altogether abandoned in England.

The following are works relating to Aristotle which are worthy of consultation, but have not been mentioned in the previous text or notes:—Stahr, *Aristotelia* (2 vols., Halle, 1830–32); *Aristoteles bei den Römern* (Leipsic, 1834). Biese, *Die Philosophie des Aristoteles* (2 vols., Berlin, 1835–42). Waitz, *Organon* (2 vols., Leipsic, 1844–46). Schwegler, *Metaphysica* (4 vols., Tubingen, 1847–48). Torstrick, *De Anima* (Berlin, 1862). Meyer, J. B., *Dissertatio de Principiis Aristotelis in distributione animalium adhibitis* (Berlin, 1854); *Aristoteles Thierkunde: ein Beitrag zur Geschichte der Zoologie, Physiologie, und alten Philosophie* (1855). Spengel, *Ueber die Rhetorik des Aristoteles* (Munich, 1851).

[1] See *The Life and Correspondence of Thomas Arnold, D.D.*, &c., by A. P. Stanley, &c., vol. ii., letter 274.

ARISTOXENUS, of Tarentum, a celebrated Greek philosopher and writer on music, was the son of Spintharus or Mnesias. He was at first a pupil of the Pythagorean school, and received instruction from Xenophilus; afterwards removing to Athens, he studied under Aristotle. He became one of the most distinguished pupils of the Peripatetic school, and is said to have been much disappointed when, after the death of Aristotle, Theophrastus was preferred to him as scholarch. His writings, which, according to Suidas, were 453 in number, have been almost entirely lost. The titles of some of them have been preserved, and show that his activity had been directed to a great variety of topics. With the exception of a few fragments quoted by other authors, there is extant of all his writings only one treatise on Harmony, in three books, which is probably not a complete work, but made up of portions of one or more separate writings. His doctrine of harmony is directly opposed to that of the Pythagoreans, according to whom musical concord depended upon certain numerical ratios, and who were obliged to reject some combinations as dissonant, only because there was no ratio corresponding to them. This theory Aristoxenus considered to be an attempt to force *a priori* determinations upon nature, and he sought to develop a theory of harmony from an empirical basis. According to him, the ear is the true judge of concord, and its impressions can be generalised into rules. His followers were called μουσικοί, or musicians by ear, in opposition to the Pythagoreans, who were κανονικοί, or musicians by rule. Another doctrine attributed to Aristoxenus brings out forcibly the strong empirical tendency of his mind. He is said to have held that the soul stood in the same relation to the parts of the body as harmony stands to the parts of a musical instrument; it was the result of organisation. What proofs he advanced in favour of this view, and how the opinion was connected with his general system of thought, we have not now the means of determining.

The best edition of Aristoxenus is by Marquard, with German translation and full commentary, *Aristoxenus' harmonische Fragmente*, 1868. The fragments are also given in Müller, *Frag. Hist. Græc.*, ii. 269, *sqq.* See also Mahne's work, *Diatribe de Aristoxeno*, 1793; and that of Brill, *Aristoxenus' rhuthmische und metrische Messungen*, 1871.

ARITHMETIC

ARITHMETIC is the science that treats of numbers, and of the methods of computing by means of them. In introducing the subject, and endeavouring to trace the progress of the science, there appear to be three points that call for particular notice, viz., the conception of number, the representation of numbers either by words or graphically by characters, and the principles and modes of computation.

1. The primary conceptions of numbers are necessarily of a very crude kind. The child attains the notion slowly by experience, and the ability that even adults have to apprehend the significance of numbers with precision is restricted to an extremely narrow area. This is still more the case among uncivilised races, some of which do not appear to be able to count beyond 3, or 4, or 5, or are at least believed to have no words in their vocabularies that express larger numbers. It is to be remembered that the knowledge that is acquired regarding numbers through experience and culture is not of numbers absolutely or in the abstract, but rests almost entirely on a perception of the relations which numbers bear to each other.

The power to form a direct and immediate conception of numbers is very limited; but the relative magnitudes of numbers, large as well as small, can be expressed with the utmost accuracy, and so as to be clearly understood. The system of notation in common use, whereby we express not merely numbers, but parts of numbers, supplies us with means of comparing arithmetically together either the greatest or the minutest magnitudes, to which there is absolutely no limit. The proportion, for instance, that the circumference of a circle bears to the diameter, though it cannot be stated with arithmetical exactness, has been calculated to upwards of 200 decimal places,—a nicety for which the vast dimensions that science discloses in the physical universe furnish no means of comparison whatever. For let it be supposed that a circle were described, with a point on the earth's surface as centre, so as to extend beyond the most distant star that can be discerned by the most powerful existing telescope, that the radius of the circle were known and that the circumference were computed from it, it does not appear that an error in the thirtieth decimal place would be of such magnitude that the keenest vision, aided by the most powerful microscope, could detect it.

In all systems of number, with the exception, perhaps, of the very rudest, numerical conceptions are aided by the introduction, usually at a very early stage, of methods of grouping. In nearly every case the methods adopted connect themselves with the number of the fingers, either of one or, more usually, of the two hands. Having reached 5 or 10, the reckoner proceeds by adding to these the prior numbers; and when a second 5 or 10 is reached, a new word or sign is employed, the significance or derivation of which is generally well marked in the name or form it bears. Similarly when (say) five fives or ten tens are reached, a fresh start is made. These processes of grouping are of great importance, conveying clearer conceptions than could otherwise be obtained of the relative magnitudes of numbers. An additional evidence of the value of the principle is to be found in certain numerical combinations which are not additive, as such combinations mostly are, but subtractive. Thus, if a conception be formed of 10, and again of 20, 19 and even 18 will connect themselves more readily with the latter than with the former, and so we have such forms as *duodeviginti* and *undeviginti;* and there is little doubt that similar considerations, in combination with a regard for brevity of expression, have led to the use of the subtractive forms IX., XL., &c.

2. There are two ways in which numbers are represented,—either in words or by particular characters or symbols. It is with the latter that arithmetic has more especially to do, the numerous important and interesting questions that relate to word-numerals falling rather within the domain of language. It is only in so far as they arise out of the systems of grouping already referred to, suggesting in their formation such processes as addition or multiplication, that these call for any notice here. Dr Tylor (*Primitive Culture*, chap. vii.) gives a variety of remarkable collocations of this sort, as well as of descriptive numerals, that are in use among different races and tribes.

There is also a common use of characters to represent numbers which does not properly belong to this subject. The letters A, B, C, &c., or α, β, γ, or the like, the order of whose succession is fixed, are often employed to indicate numerical order, either singly or in combination with numerals proper. This is not, however, an arithmetical use of the characters; they are merely *ordinals*, and cannot furnish a basis for calculation.

The origin of the various characters which have been employed to indicate numbers proper, and by means of which computations can be effected, is in most cases alphabetical. In the Hebrew and Greek notations, for instance, the letters were taken in the main in their alphabetical order, being divided into three groups, of which the first represented units, the second tens, and the third hundreds; and very similar systems have been in use among other nations. As the Hebrew alphabet contained no more than twenty-two letters, the numbers from 500 to 900 were represented by five final forms, and sometimes by additive combinations with ת, 400. The following is the usual Hebrew notation, numbers exceeding ten being made up by placing the larger numeral characters first:—

א	ב	ג	ד	ה	ו	ז	ח	ט
1	2	3	4	5	6	7	8	9
י	כ	ל	מ	נ	ס	ע	פ	צ
10	20	30	40	50	60	70	80	90
ק	ר	ש	ת	ך	ם	ן	ף	ץ
100	200	300	400	500	600	700	800	900

The ordinary Greek notation has not merely a general resemblance of structure to the Hebrew, but corresponds to it closely, character for character, up to 80. The Greek alphabet consisting of twenty-four letters, three additional characters were introduced. The first, for 6, occupying the place of ו, is ϛ (named σταῦ), which was afterwards used as a contraction for στ; the others, for 90 and 900, were named κόππα and σαμπῖ respectively, and written ϙ or ϟ and ϡ. The notation is thus as follows:—

α	β	γ	δ	ε	ϛ	ζ	η	θ
1	2	3	4	5	6	7	8	9
ι	κ	λ	μ	ν	ξ	ο	π	ϙ or ϟ
10	20	30	40	50	60	70	80	90
ρ	σ	τ	υ	φ	χ	ψ	ω	ϡ
100	200	300	400	500	600	700	800	900

To distinguish the numeral letters an accent was written after the last,—thus, 38 was λή, while thousands were indicated by writing the accent below,—thus ͵δ was 4000. The letter M (for μυρίοι) increased the numeral 10,000 times. Fractions were separated by a space from the integers they were affixed to, and the denominator was written like an index or power in our notation,—thus, $\mu\gamma\ \theta^{\iota\alpha}$ was $43\frac{9}{11}$.

In addition to this another entirely different notation is found in Greek inscriptions. It more nearly resembles the Roman system, the numeral characters (except the first) being the initials of the numeral names, and being repeated till the number to be signified was expressed. I represents, 1, Π (πέντε) 5, Δ (δέκα) 10, H (ἑκατόν, the aspirate being written as an H) 100, X (χίλιοι) 1000, M (μυρίοι) 10,000. Characters enclosed within three lines (forming a Π) are thereby multiplied by 5. To give an example, in this notation |H̅| HH |Δ̅| ΔΠIII represents 768.

The Roman system, with which we are still familiar nearly in its completeness, employs the letters of the alphabet, but is not based upon alphabetical order. Many attempts have been made to account for the symbols, and the complete solution of the problem of their origination is perhaps unattainable. Sir John Leslie, following some writers of the 16th and 17th centuries (see in particular the *Cursus Mathematicus* of Dechâles, vol. i. 1674, 2d. ed. 1690), advocated the opinion that, one line or stroke being taken to represent the unit, when ten of these were set down, a stroke would be drawn across them in a slanting direction to cancel them, and the unit stroke and cancelling stroke would thus give the form X for 10; that a repetition of this proceeding would give a third stroke when 100 was reached, and the three might take the form ⊏ or C; and that, similarly, the combination of four strokes would give M for 1000. This explanation is perhaps too ingenious. It has the merit of accounting for the X (the *crux* of the method), which may have been introduced in some such way. But one does not readily see how the ⊏ could be formed from the X, or the M from the ⊏; and it appears far more likely that the signs for 100 and 1000 are merely the initial letters of *Centum* and *Mille*,—all the more that the very ancient notation noticed above as found in Greek inscriptions has evidently an origin of this kind. In any case V, L, and D appear to be respectively the halves of X, the angular C (⊏), and the rounded M (ꟿ). The ancient forms of D and M, viz., IↃ and CIↃ, have ceased to be familiar. By an extension of this style of characters, IↃↃ denoted 5000; CCIↃↃ, 100,000; CCCIↃↃↃ, 1,000,000, &c. To represent two, three, &c., millions, the CCCIↃↃↃ was repeated the required number of times.

The Roman notation employs fewer characters than the Greek, and makes greater use of combinations. One is repeated up to four; to the new character for five, ones are repeated up to nine; ones are added to the ten character; at fifteen the five enters, and so at twenty-five, &c.; for the tens up to forty the ten is repeated, and so on,—the symbols I, V, X, L, C, D expressing all numbers by regular combinations up to M, a thousand. The subtractive collocations, IV, IX, XL, XC, now the ordinary, were originally alternative forms, as were also the rarer combinations IIX for 8, XIIX for 18, XXC for 80, &c. To the extent of these subtractive forms, the values of the characters depended on their position, a smaller number being added to a greater when it followed, and subtracted from it when it preceded it. This element of position is, however, an irregular and exceptional one; and, instead of being of such advantage as the local value of the Arabic notation, is rather a hindrance in calculation.

Far superior to all the ancient systems, and indeed to every other system that exists, is the arithmetical notation that is in common use. The Arabic numerals, as they are called, are ten in number, nine of them representing the first nine numbers, and the tenth, the cipher or zero, indicating the absence or negation of numerical value. The significance of these figures or digits depends on their relative position, and the great merit of the system is due to this element of local value. Standing singly, the figures denote simply one, two, three, &c.; but in combinations of them every removal towards the left increases the value of the figure ten times. In 5673, for instance, the 3 denotes three, the 7 seven tens (70), the 6 six times ten tens (600), the 5 five times ten hundreds (5000). Should any of the series of tens be wanting, as in nine thousand and forty-eight, where hundreds do not occur, the place is supplied by a cipher, which throws back the digit that expresses thousands into its proper place, thus 9048. It is by this use of the cipher in supplying blanks, and so regulating the places of the significant digits, that the principle of local value is carried out. See further the sections on notation and numeration below, p. 527.

The ordinary numerals are called Arabic, and it appears to have been through the Arabians that they were introduced into Europe; but they are now generally acknowledged to be of Indian origin. As may be imagined, they have passed through a great variety of forms, one of the earliest types of them being the *Devanagari*, a species of Sanskrit numerals. In the early Indian treatise of Bhascara and Brahmegupta, translated by Mr Colebrooke (see article ALGEBRA, p. 517 of vol. i.), as well as in the still earlier writings of Arya-Bhatta, there are both indications and illustrations of the use of the nine digits and the cipher;

and the system is thus traced back to the 7th, and in all probability to the 5th century of the Christian era. Even then it was evidently no novelty, but is alluded to as holding an established position; and the Hindu writers nowhere lay claim to the invention of it, but constantly assign to it a supernatural origin. The method was known to the Arabians in the 9th century; and in the course of the 10th it seems to have come into general use among them, especially in their astronomical writings and tables. It was probably in the following century that the Arabs introduced the notation into Spain, but in regard to this we have no explicit information, and different accounts are given of the earliest instances of the use of the system in Europe. On the one hand, it is alleged that the figures first occur in a translation of Ptolemy, of the date 1136, while others maintain that they were introduced (about 1252) by means of the celebrated astronomical tables published by and named from Alphonso the Wise. That their use was known in Italy at the commencement of the 13th century, appears to be satisfactorily established, for there is no good reason to doubt the genuineness of the MS. writings of Leonardo of Pisa, copies of which have been found bearing the dates 1202 and 1220. Numerous other instances are given of the early use of the nine figures and the cipher, especially by astronomers, and in calendars. The great superiority of this to earlier modes of numerical expression became gradually apparent, and in course of time it came into almost universal use among civilised nations.

For a time there was, not unnaturally, considerable inexactness or confusion in the employment of the notation. In early writings such combinations are found, for example, as X2 for 12, 301 for 31, &c. In the latter case the law of local value is lost sight of, and the characters 30 are used as equivalent to thirty, irrespective of their position.

3. Calculation or computation by means of numerical characters is what is ordinarily regarded as the distinctive province of arithmetic, and the worth of a system of notation is to be estimated by the facilities it affords for the operations of reckoning. The methods in common use will be detailed, and the principles on which they depend briefly expounded, in subsequent sections of this article.

Computation of a comparatively rude kind was often carried on in ancient times, and is practised still in some countries, by what are called palpable methods,—as, for instance, by means of counters, or by balls strung on rods or running in grooves. Of this the abacus of the Romans (used too, but not so generally, among the Greeks), the swan-pan, still in constant use among the Chinese, &c., are examples. (See ABACUS, vol. i. p. 4.)

The methods that preceded the adoption of the Arabic numerals were all comparatively unwieldy, and very simple processes involved great labour. The notation of the Romans, in particular, could adapt itself so ill to arithmetical operations, that nearly all their calculations had to be made by the abacus. One of the best and most manageable of the ancient systems is the Greek, though that too is very clumsy, as may be seen from an elementary example.

Let it be required to muliply 862 by 523, *i.e.*, ωξβʹ by φκγʹ. The product of ω and φ is 400,000, *i.e.*, $\mu_{\times}$; of ξ and φ, 30,000, or $\gamma_{\times}$; of β and φ, 1000, or ͵α. Similarly the multiplication of ω by κ gives 16,000, or $\alpha_{\times}$͵ϛ; of ξ by κ, ͵ασ; of β by κ, μ; of ω by γ, ͵βυ; of ξ by γ, ρπ; and of β by γ, ϛ. These may be arranged in some such order as in the margin, and summed. The result is $\mu_{\times}\epsilon_{\times}$ωκϛʹ, or 450,856.

$$\begin{array}{rr}
 & \omega\,\xi\,\beta \\
 & \underline{\phi\,\kappa\,\gamma} \\
\mu_{\times}\gamma_{\times}{}_{,}\alpha & \\
\alpha_{\times}{}_{,}\varsigma & \\
 & \alpha\,\sigma\,\mu \\
 & {}_{,}\beta\,\upsilon \\
 & \underline{\rho\,\pi\,\varsigma} \\
\mu_{\times}\epsilon_{\times} & \omega\,\kappa\,\varsigma
\end{array}$$

The notation employed here extends to hundreds of millions. A scheme proposed by Archimedes, the most distinguished mathematician of antiquity, in his work entitled Ψαμμίτης, *Arenarius*, goes far beyond this. Taking the limit of the ordinary system, viz., a myriad of myriads, or 100,000,000, as the basis of a new scale, he treats of numbers formed by the continued product of that amount repeated eight times, extending to sixty-four places in our notation. These he divided into what we should call periods, of eight figures each, to which he gave the name of *octades*. He thus appears to have to some extent anticipated the modern method of grouping, though, from the want of knowledge of the principle of local value, the practical advance he made was unimportant. Apollonius of Perga, who flourished a little after the time of Archimedes, took the myriad as the basis of his system, and repeated the sign Mυ for each product of a myriad; thus λδMυ.Mυ.Mυ indicates what we would write as 34,000,000,000,000. But his most important contribution to arithmetical science was his grouping the tens in multiplication, so as to connect large numbers, as far as possible, with those we represent by the nine digits. He thus endeavoured, and with some measure of success, to remedy the defect of the general system arising from the want of apparent connection of such characters as λ and τ, for example, or π and ω, with what he called their bases, γ and η. It is chiefly in the commentaries of Eutocius on the works of Archimedes and Apollonius that the examples of the ancient Greek arithmetic which we possess are preserved.

The operations of the Greek arithmetic involving fractions were necessarily very complicated. A simpler system was introduced (by Ptolemy, according to his commentator Theon, but it appears to have existed before his time) in what are known as *sexagesimals*, which are precisely analogous to the duodecimals by which we sometimes calculate areas. The division of the circle into 360 degrees arose, no doubt, from 360 approximating the number of days in the year, and containing a large number of divisors. The radius of the circle, or side of the inscribed hexagon, subtended at the centre 60 of these degrees, and from this the degree was again divided into 60 parts called minutes, the minute into 60 seconds, &c., just as the foot is divided into 12 inches, the inch into 12 seconds, &c., in duodecimals. The sexagesimal system, though applied in the first instance to circular, was also employed in linear, measurements. As an example, the square of λζ δ νε, *i.e.*, of 37° 4′ 55′, will be found to be ͵ατοε δ ιδ ι κε, *i.e.*, 1375° 4′ 14″ 10‴ 25⁗ The numerals beyond 60 or ξ being dispensed with in this system, the next letter, *o*, was used to denote zero; and it has been conjectured that this may have been the origin of the form of our cipher.

The most important step in the progress of modern arithmetic was the introduction of decimal fractions, and the extension of the Arabic notation to the expression of them. The first writer who advocated and exemplified the use of decimals was Simon Stevin de Bruges, better known as Stevinus, in a paper (*La Disme*) published about 1585; but he employed an awkward notation, and it was only after a considerable period that they assumed the form—entirely consistent with the notation of integers—with which we are familiar. From a form which Lord Napier employs in his *Rabdologia* (1617), the introduction of the decimal point (as a comma) has been ascribed to him, but apparently without sufficient evidence.

The following writers on arithmetic may be named, in addition to those already mentioned:—Diophantus, who flourished in or about the 4th century; Maximus Planudes, who died about 1350; Lucas Pacioli (de Burgo, or di Borgo), whose *Summa de Arithmetica* (1494) was the first work on algebra printed, and one of the earliest on arithmetic; Bishop Tonstall, whose *De Arte Supputandi* (1522) was the first work on the subject printed in English;

Robert Recorde (died 1558), whose *Grounde of Artes* and *Whetstone of Witte* were arithmetical works of great value; Nicolo Tartaglia (died 1559); Michael Stiefel or Stifelius (1486–1567), said to have been the inventor of the signs + and −; Peter Ramus (1515–1572); Albert Girard (died 1634); William Oughtred (died 1660); Edward Cocker, whose *Arithmetic* (1st ed. 1677), a posthumous work, and probably a forgery, is of slight merit, though it passed through many editions; Kästner (*Geschichte der Mathematik*, 4 vols. 1796–1800); Montucla (*Histoire des Mathématiques*, vol. i. 1799), De Morgan (*Arithmetical Books*, 1847). By far the best history of arithmetic is that of Dr George Peacock, late Dean of Ely, published in the *Encyclopædia Metropolitana*

Of recent works on arithmetic there is great abundance, and many of them are of great excellence. They usually contain statements of modes of operation, under the name of "Rules," with a number of examples under each for practice; and not a few of them give in addition explanations of the *rationale* of the methods.

In the following sections the ordinary processes of arithmetical calculation and their commonest practical uses are briefly explained. The various methods of operation are given with greater or less detail, as has appeared necessary for the exposition of the principles on which the operations depend; and light is in many instances thrown on both processes and principles by illustrative examples. For further examples the reader is referred to the manuals above alluded to. The earlier sections, forming the greater part of the article, are occupied with numbers in the abstract, and the remainder with arithmetic in its practical applications.

I. Abstract Arithmetic.

Notation.

1. *Notation* is the name usually given to the expressing numbers by means of characters or figures.

The number ten is the basis or *radix* of the Arabic system of notation, and every number may be expressed in that notation by combinations of the ten *digits*, or numeral figures, 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, the last (the cipher or *zero*) having no value except in combination. When several of these are placed together, every removal towards the left increases the value of a figure ten times. The figure placed furthest to the right has the same significance as when it stands alone, *i.e.*, it represents units, the figure next to it denotes tens, the next hundreds, the next thousands; 8735 is therefore read as eight thousand seven hundred and thirty-five. With more than four figures we should have—still proceeding to the left—tens of thousands; then hundreds of thousands, and then thousands of thousands; but instead of this we use the term millions. A million of millions is a billion,[1] and a million of billions a trillion. A digit followed by three figures thus expresses thousands; by six figures, millions; by twelve, billions; and so on. Beyond trillions we have—taking the figures in groups of six—quadrillions, quintillions, sextillions, septillions, octillions, nonillions, &c. But occasion is very seldom found to employ these terms, and indeed it is difficult to form any distinct or definite idea of even a billion.

The system of notation in ordinary use is remarkable at once for its simplicity and its completeness. The selection of ten as the basis or radix of the system (whence numbers expressed in this way are said to be in the *denary* scale of notation) is in all probability to be traced to primitive calculations by means of the ten fingers. Ten is well chosen, being neither too large nor too small, but twelve might, in some respects, have been found more convenient. All numbers can be expressed with twelve or any other number as basis, just as with ten.[2]

2. *Numeration* is the art of reading figures employed to express numbers. The following table shows the places of the figures, as already described, up to billions:— Numeration.

(1.) Units
(2.) Tens.
(3.) Hundreds.
(4.) Thousands.
(5.) Tens of thousands
(6.) Hundreds of thousands.
(7.) Millions.
(8.) Tens of millions.
(9.) Hundreds of millions.
(10.) Thousands of millions.
(11.) Tens of thousands of millions.
(12.) Hundreds of thousands of millions.
(13.) Billions.

The figures 8,607,034,740,952, for example, are read thus:—Eight billions, six hundred and seven thousand and thirty-four millions, seven hundred and forty thousand, nine hundred and fifty-two. Ciphers are passed over in reading, their function being to determine the proper position of the significant figures. When the number of figures exceeds four, it is usual to print them off as above in groups of three, by means of commas. At the *odd* commas, reckoning from the right hand, we always read thousands; at the *even* commas, millions, billions, &c.

3. *Notation* has, in addition to the general meaning already explained, a special signification as the converse of numeration, *i.e.*, it is the art of representing by figures numbers that are given expressed in words.

4. *Addition* is the method of finding the *sum* of two or more given numbers, that is, the number to which they amount when taken together. Addition

Suppose a column, added in the ordinary way, amounts to 34. The 4 is set down under the column, and the 3, representing 30, is added with (or, as usually expressed, "carried to") the next column.

5. *Subtraction* is the method of finding the *difference* between two given numbers, that is, the number by which the greater number exceeds the less, or the *remainder* after the less is taken from the greater. Subtraction

In subtracting, say, 38 from 92, since 8 cannot be taken from 2, we "borrow" from the place of tens, *i.e.*, the 2 is increased by 10, and 8 taken from 12 leaves 4. The 10 added (or "borrowed") has to be taken away again, and this is done by taking 1 from 9 in the place of tens. But 3 has also to be taken from this 9; so first of all the 1 and 3 are added together, *i.e*, 1 is "carried" to the 3, and 4 taken from 9 leaves 5, giving 54 as the complete remainder. The "borrowing" process depends on the consideration that when the same amount is added to both numbers their difference is unaltered—it being remembered that *ten* in the upper line corresponds to *one* a place towards the left in the lower line.

6. *Multiplication* is a method of finding the result produced by adding a given number taken a given number of times. The number to be repeated is called the *multiplicand;* the number expressing the times it is taken, the *multiplier;* and the result obtained, the *product*. The Multiplication.

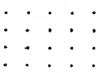
[1] In France, and by a few English writers a *thousand* millions is called a billion, a *thousand* billions a trillion, &c. The ordinary English usage is at least as convenient, and agrees (which the other does not) with the etymological formation of the words—the billion, trillion, quadrillion, &c., being respectively the second, third, fourth, &c., powers of a million.

[2] With twelve as basis (*i.e.*, in the *duodenary* scale), the number represented by the figures 8735 would be the sum of $8 \times 12 \times 12 \times 12$, $7 \times 12 \times 12$, 3×12, and 5, *i.e.*, 14,873 in the ordinary or denary scale. To convert 8735 of the denary into the duodenary scale, we find the twelves in it, that is, divide it by 12, the quotient by 12, &c. This gives (using the character *e* for eleven), 507*e*.

multiplicand and multiplier are also said to be *factors* of the product.

The multiplicand might be written down the required number of times, and the sum found by addition. But this tedious process is unnecessary when the numbers to be added are all the same We do not then require to pass from figure to figure, as when they are different. In adding six nines, for instance, we do not need to proceed step by step (as with $6+5+9+8+6+7=41$), but know the result, 54, at once from a table of products which is committed to memory.

When two numbers are to be multiplied together, either may be taken as the multiplier. For it is evident that the four rows of dots, five in a row, in the margin, are the same as the five rows, four in a row—according as we take the rows horizontally or vertically; that is, 4 times 5 and 5 times 4 amount to the same number.



The process of multiplication by a single digit—by 8, for instance—is nothing but an abridgement of the operation of writing the multiplicand eight times and adding. When there are more digits than one in the multiplier, we arrange the successive products in the well-known fashion, because the multiplication has to be by 10 times the second digit (counting from the right), 100 times the third, and so on. Thus, in multiplying 92058 by 734, the 2 of the multiplicand is really 2000; the 3 of the multiplier, 30; and the product of these, 6, *i.e.*, 60,000, falls by the ordinary process into its proper place.

The process of working may sometimes be considerably shortened by multiplying a product already obtained. Thus, to multiply by 568, we may multiply first by 8, and then take 7 times the result, obtaining the product by 56 at once. So with 549378, we may begin with 9, and multiply the 9 product by 6 for 54, and the 54 product by 7 for 378, observing to arrange the lines correctly, by placing under the right-hand figure of every multiplier the right-hand figure of the corresponding product.

Division. 7. *Division* is the method of finding how often one given number contains another.

Of these two numbers, the former is called the *dividend*, and the latter the *divisor*. The number expressing the times that the first contains the second is called the *quotient*. When the number of times is not exact, the excess of the dividend over the divisor taken the greatest number of times that the dividend contains it exactly is called the *remainder*.

As multiplication is a short method of addition, division (which is the converse of multiplication) is an abridged subtraction. Were we to subtract the divisor from the dividend, subtract it again from the remainder, and continue the process till a remainder less than the divisor were obtained, the number of subtractions would give the required quotient. But this operation is greatly shortened by means of multiplication. Thus, if it is required to find how often 9 is contained in 49, remembering that 5×9 is 45, and that this is the nearest product not greater than 49, we have at once the quotient 5 and remainder 4.

In dividing, *e.g.*, 167685 by 287, by the ordinary process of *long division*, we find (after, it may be, a trial or two) that 1676 is more than 5 times but less than 6 times 287. The first quotient figure is therefore 5, representing 500; and proceeding in the customary way, we take from the dividend 500 times the divisor, then 80 times, and then 4 times, with 77 over. The dividend, therefore, contains the divisor 584 times, with a remainder of 77.

When the divisor does not exceed 12, the operation is conducted mentally, and the quotient set down at once. This is called *short division*. If the divisor is made up of factors not greater than 12, short division may be employed, the factors being taken in succession. When there are two such divisors, the remainder of the whole division is obtained from the partial remainders, by multiplying the second of these by the first divisor, and adding the first to the product. Thus, in the annexed example, division by 48 gives a remainder of 32, for it will be seen that 725 is 5 more than 8 times 90, and 4352 is 2 more than 6 times 725. Therefore, 4352 is 2 more than the sum of 48 times 90 and 6 times 5, *i.e.*, it exceeds 48 times 90 by $6\times5+2=32$, or contains 48 90 times and 32 over.

```
6)4352
8)725—2
   90—5
```

Measures and Multiples of Numbers.—8. A *measure* of any number is a number that divides it without a remainder. A *multiple* of any number is a number that it divides without a remainder. A *common measure*, or *common multiple* of several numbers, is a number which is a measure or a multiple of each of them. Thus, 3 is a common measure of 12, 18, and 24; 60 is a common multiple of 6, 10, and 15. A measure of a number is sometimes called a *submultiple* of it. Measures and multiples.

A *prime number* is a number which no other, except unity, divides without a remainder; as 2, 3, 5, 7, 11, 13, 17, &c. Numbers which are divisible by other numbers without remainder, that is, which can be resolved into factors, are called *composite numbers*; as 4, 6, 8, 9, 10, &c. Any factors into which a composite number can be divided are called its *component parts*. Numbers are said to be *prime to each other* when they have no common measure, as 15 and 28. The *prime factors* of a number are the prime numbers of which it is the continued product. Thus, 2, 3, 7 are the prime factors of 42; 2, 2, 3, 5, of 60

9. To find the *greatest common measure* of two given numbers, the greater number is divided by the less; the former divisor is then divided by the remainder, and each successive divisor by the remainder obtained in dividing by it, till there is no remainder. The last divisor is the greatest common measure. Greatest common measure.

This depends on the two following principles:—(1.) If a number measures any other, it measures every multiple of that other; for obviously, since 7 measures 56, it also measures 12 times or 17 times 56; and, (2.) Every number that is a common measure of two others measures also their sum or their difference; for the sum or difference of, say, 13 times 8 and 22 times 8, must, it is evident, be some multiple of 8.

Thus, to find the greatest common measure of 475 and 589, dividing 589 by 475, we have the remainder 114; dividing 475 by 114, we have the remainder 19; and 114 divided by 19 leaves no remainder. Therefore, 19 is the greatest common measure. For any number that measures 589 and 475 will measure their difference, 114, and will, therefore, measure 456, which is a multiple of 114. Also, any common measure of 475 and 456 will measure their difference, 19. Therefore, no number greater than 19 can measure both 589 and 475. Again, 19 will measure both, for it measures 114, and therefore measures 456, a multiple of 114. Hence it measures 475, which is $456+19$, and also 589, which is $475+114$. Therefore, 19 measures both numbers, and since no greater number does so, it is their greatest common measure.

In seeking for measures or factors, it will be of advantage to attend to the following properties of numbers. (For the sake of brevity, we use "divisible" here for "divisible without remainder.")

(1.) A number is divisible by 2, if the last digit is divisible by 2; by 4, if the last *two* digits are divisible by 4; and by 8, if the last *three* digits are divisible by 8. For, to take the last case, the figures preceding the last three are a multiple of 1000, which is a multiple of 8. If, then, the last three figures are divisible by 8, so is the whole number.

(2.) Similarly, and for precisely similar reasons, a number is divisible by 5, if its last digit is so; *i.e.*, if the number ends with 5 or 0; by 25, if it ends with 25 or 75; and by 125, if it ends with 125, 625, 375, or 875.

(3.) A number is divisible by 9 when the sum of its digits is so divisible. This is a case of the important property that the division of a number by 9 produces the same remainder as the division of the sum of its digits by 9. Taking any number, *e.g.*, 583, we see that it is made up of 58 tens and 3; that is, of 58 nines and 58 and 3. Again, 58 is 5 tens and 8; that is, 5 nines and 5 and 8. Thus, 583 is made up of 58 nines, 5 nines, and $5+8+3$; that is, of nines + the sum of its digits. Therefore 583 and $5+8+3$ must give the same remainder when divided by 9.

A proof of multiplication, by "casting out the nines," depends on this property. If a number, made up, say, of nines and 7 over, be multiplied by another made up of nines and 5 over, their product must be nines and 35, that is, nines and 8 over; and unless this relation holds good, there must be an error in the multiplication.

(4.) Similarly, a number is divisible by 3, if the sum of its digits is so; for, if every number be made up of nines and the sum of its digits, it must be made of threes and the same sum.

(5.) A number is divisible by 11, if the sums of its alternate digits are equal, or if they differ by a multiple of 11. Take any number whose alternate digits are equal, or differ by a multiple of 11, as 8294. This is equal to the sum of 8000, 200, 90, and 4; that is, of 80 times 99, 80, twice 99, 2, 90, and 4. Leaving out the multiples of 99 (as being multiples of 11), we have $80+90+2+4$. But as $2+4$ and a multiple of 11 give $8+9$, therefore, if $80+90+2+4$ be divisible by 11, so must $80+90+8+9$ be, and *vice versa*. But $88+99$ is divisible by 11; so, therefore, is $80+90+2+4$, and so also 8294.

If, in finding the greatest common measure by the method described, a divisor occurs containing a factor that evidently does not measure one of the numbers given, that factor may at once be omitted, since it can be no part of the common measure. Thus, in finding the greatest common measure of 59241 and 223014, we get 13950 as a divisor. Now, 50 divides this, *i.e.*, $5 \times 5 \times 2$, and neither 5 nor 2 measures the first of the given numbers. We can therefore reduce 13950 to 279 at once, whence we immediately find 93 to be the greatest common measure.

Least common multiple

10. To find the *least common multiple* of two given numbers, divide either of the numbers by the greatest common measure of the two, and multiply the other number by the quotient. Thus, the greatest common measure of 30 and 48 is 6. Therefore the least common multiple is 48×5 or 30×8, *i.e.*, 240. For the product $5 \times 6 \times 8$ is evidently a common multiple of 30 (*i.e.*, 5×6) and 48 (*i.e.*, 6×8), and since 8 and 5 are prime to each other, this product must be the least that contains both 5×6 and 6×8.

To find the least common multiple of any given numbers, arrange them in a line, and strike out any of them that measure any of the others; take any number that measures all or part of the remainder, and divide all that it measures by that number, setting down the quotients and the undivided numbers in a second line; proceed with this second line as with the first, and continue this process till a line is obtained of numbers prime to each other. The continued product of the divisors and the numbers in the last line is the least common multiple required. This depends on the principle just demonstrated, that a common factor of two or more numbers needs to be taken but once for the common multiple.

In finding the least common multiple of 42, 45, 50, 54, 60, 63, 70, 75, and 90, for instance, we may divide in succession by 5, 7, 5, and 6. It is evident that 45 may be omitted, since it will measure every multiple of 90. The division by 5 is virtually the substitution for 50, 60, 70, 75, and 90, of the product $5 \times 10 \times 12 \times 14 \times 15 \times 18$, which is manifestly a common multiple of them. Then 14 and 18 are omitted, being contained in 42 and 54. Next we substitute for 42 and 63 the product $7 \times 6 \times 9$; omit 6 and 9 as being contained in 54; then take $5 \times 2 \times 3$, instead of 10 and 15; omit 2 and 3, as measures of 12; and, lastly, substitute $6 \times 9 \times 2$ for 54 and 12. The product of 5, 7, 5, 6, 9, 2, gives 18900 as the least common multiple.

If the divisors are all prime numbers, the result must be the *least* common multiple; and it is better to avoid using composite numbers as divisors, except when they measure *all* the numbers in the line. Had 10, for instance, been taken in the example as the first divisor, 75 would have remained in the second line, and the result obtained would have been five times too great. It is often found convenient to write the prime factors of the least common multiple, which is in the example $2 \times 2 \times 3 \times 3 \times 3 \times 5 \times 5 \times 7$.

Fractions.—11. If unity be divided into any number of equal parts, one or more of these parts is called a *fraction*. If, for example, we divide unity into 7 equal parts, and take 5 of these, we shall obtain the fraction we speak of as five-sevenths. (This, and what follows, may be familiarly illustrated by taking any object and dividing it in the way described—a straight line, for instance, thus, .) Fractions.

There are two kinds of fractions—*Vulgar Fractions*, often spoken of simply as *Fractions*, and *Decimal Fractions* or *Decimals*.

A vulgar fraction is represented by two numbers, called the *terms* of the fraction, which are written, the one above and the other below a horizontal line; thus, the fraction already mentioned is written $\frac{5}{7}$. The number under the line indicates the number of equal parts into which unity is divided, and is called the *denominator*,[1] as showing the "denomination" (see § 32) of the fraction. The number above the line, indicating the number of those equal parts that the fraction consists of, is called the *numerator*.

The most usual definition of a fraction is that which is given above. But it may be also defined or regarded as one number divided by another, the numerator being the dividend, and the denominator the divisor. Thus, the fraction $\frac{5}{7}$, which we have interpreted to mean 5 of the 7 parts into which unity is supposed to be divided, may also be regarded as the seventh part of 5 units. For, if each of 5 units be divided into 7 equal parts, there will be in all 35 of these parts, each of them equal to the seventh part of unity, and the seventh part of these 35 parts is 5 of them. That is, the seventh part of 5 units is the same as 5 seventh parts of unity, or $\frac{5}{7}$ according to the former definition. It follows from this that, when there is a remainder after division, the quotient is completed by the addition of a fraction, of which the remainder is the

[1] Though the word employed to express the denominator (*e.g.*, the "sevenths" in "five-sevenths") agrees in form with the ordinal numeral, this use of it is not ordinal. *The seventh day* means the seventh in order of time; but *the seventh part of a day* is one, *any* one of seven equal parts into which the day is regarded as divided. Some such distinct name as "fractional numerals" should be given to the words when used in the latter sense. The expressions "first part" and "second part" are never used in the fractional sense. For the latter "half" is used; there is no fractional corresponding to the former. $\frac{1}{32}$, however, is called the thirty-second part; and so $\frac{9}{32}$, $\frac{4}{21}$, &c., are read *nine thirty-seconds*, *four twenty-firsts*, &c.

numerator, and the divisor the denominator. For, let it be required to divide 76 by 9. Since 72 divided by 9 gives the quotient 8, and 4 divided by 9 gives $\frac{4}{9}$, 76 divided by 9 must be $8\frac{4}{9}$.

A *proper fraction* is one whose numerator is less than its denominator; as $\frac{9}{10}$, $\frac{12}{20}$. An *improper fraction* is one whose numerator is not less than its denominator; as $\frac{5}{5}$, $\frac{9}{5}$. A proper fraction is evidently less, and an improper fraction not less, than unity. A *mixed number* is an integer or whole number with a fraction annexed to it; as $8\frac{1}{2}$, $5\frac{7}{12}$. The integer and fraction here are to be considered as added together. A *simple fraction* is a single fraction that has both its terms whole numbers; as $\frac{4}{5}$, $\frac{8}{5}$. A *compound fraction* is a fraction of another fraction, or of a whole or mixed number; as $\frac{2}{3}$ of $\frac{5}{6}$, $\frac{3}{8}$ of $10\frac{2}{3}$. A *complex fraction* is one that has a fraction or mixed number for one of its terms or for both; as $\frac{\frac{3}{4}}{4\frac{1}{3}}$, $\frac{3}{4\frac{2}{7}}$, $\frac{6\frac{2}{3}}{5}$. A fraction is said to be *in its lowest terms* when the numerator and denominator have no common divisor.

12. If both terms of a fraction be multiplied, or both divided, by the same number, the value of the fraction will remain unchanged. For, if unity be divided into 7 equal parts, and again into 28 equal parts, it is evident that each of the former parts will be identical with 4 of the latter. 5 of the former will thus be equal to 20 of the latter; that is, $\frac{5}{7}=\frac{20}{28}$.

13. We multiply or divide a fraction by any number, if we multiply or divide the numerator by it. For it is evident that four times $\frac{2}{9}$ is $\frac{8}{9}$, since unity is divided into 9 parts in both cases, and the number of parts taken in the one case is four times the number taken in the other. Conversely, dividing $\frac{8}{9}$ by 4, we have $\frac{2}{9}$.

To multiply or divide either term of a fraction is the same as to divide or multiply the other. If, for instance, we divide the denominator by 3, we divide unity into one-third of the number of parts, and each of these parts must thus be three times greater than before. The fraction is therefore multiplied by 3. Or otherwise, dividing the denominator of $\frac{2}{9}$ by 3, we obtain $\frac{2}{3}$; and multiplying the numerator by 3, we get $\frac{6}{9}$, which (§ 12) is the same as $\frac{2}{3}$. Therefore, to divide a fraction, we may multiply the denominator,—a method which must be employed when the divisor is not a measure of the numerator.

14. To reduce a fraction to its *lowest terms*, divide both terms by their greatest common measure. The reason of this is evident from the definitions. The value of the fraction remains unchanged (§ 12). The results of operations in fractions should, with rare exceptions, be expressed in their lowest terms.

15. To reduce a *mixed number* to an *improper fraction*, the integer is multiplied by the denominator of the fraction, and the numerator added to the product. This gives the numerator of the required improper fraction, and the denominator of the given fraction is its denominator. Take, *e.g.*, $4\frac{5}{8}$. If unity be divided into 8 equal parts, 4 units will make 32 of these parts, and the fraction $\frac{5}{8}$ contains 5 of them; therefore $4\frac{5}{8}=\frac{37}{8}$. Conversely, to reduce an *improper fraction* to a *whole* or *mixed number*, divide the numerator by the denominator; the quotient is the integer required, and the remainder, if there is one, is the numerator of a fraction of which the given denominator is the denominator. Thus, $\frac{38}{7}=5\frac{3}{7}$; for, if unity be divided into 7 equal parts, 35 of these parts will be the same as 5 units; therefore 38 parts will be 5 units and 3 parts, *i.e.*, $\frac{38}{7}=5\frac{3}{7}$.

16. To reduce a *compound fraction* to a *simple one*, multiply the numerators together for the numerator of the simple fraction, and the denominators together for its denominator. Thus, $\frac{3}{4}$ of $\frac{5}{7}$ is equal to $\frac{15}{28}$. For, if we divide unity into 7 equal parts, and each of these again into 4, we shall have for the fraction $\frac{5}{7}$ 20 of these parts, *i.e.*, $\frac{20}{28}$ of unity. The fourth part of this is 5 of these parts, and therefore $\frac{3}{4}$ is 15 of them, *i.e.*, $\frac{3}{4}$ of $\frac{5}{7}$ is $\frac{15}{28}$.

Mixed numbers must be put in the form of improper fractions before the multiplication. The reduction of the result to its lowest terms may be effected by removing before multiplication any factors that are common to the numerators and denominators.

In such compound expressions as where one number is spoken of as one-fourth greater or less than another, the fourth is always to be taken of that number with which the comparison is made. Thus, 30 is *one-fifth* more than 25 (*i.e.*, $\frac{1}{5}$ of 25), but 25 is *one-sixth* less than 30 (*i.e.*, $\frac{1}{6}$ of 30).

17. In order to compare the values of fractions, or to add or subtract them, it is necessary to reduce them to others of equal value that *have the same denominator*. From the definition of a fraction we see at once that $\frac{5}{7}$ is greater than $\frac{4}{7}$, but we do not readily see whether $\frac{5}{12}$ is greater or less than $\frac{3}{8}$. If, however, we take the equivalents of these fractions, $\frac{10}{24}$ and $\frac{9}{24}$, unity being now divided into the same number of parts in both cases, we have like quantities to compare, and see that the former fraction is the greater. In practice it is usually the *least* common denominator that the fractions are compared by. To find this, we first find the least common multiple of the denominators (§ 10), then divide this by the denominator of each fraction separately, and multiply both terms of that fraction by the quotient.

Take, *e.g.*, the fractions $\frac{13}{15}$, $\frac{17}{20}$, $\frac{31}{36}$, and $\frac{38}{45}$. The least common multiple of the denominators is 180, and dividing this by 15, 20, 36, and 45, we get 12, 9, 5, and 4. Multiplying both terms of the fractions in succession by these numbers, we have $\frac{156}{180}$, $\frac{153}{180}$, $\frac{155}{180}$, and $\frac{152}{180}$. The value of the fractions has not been altered, and all have now the same denominator, 180, which we must obtain in each case, because we re-multiply the factors into which we resolved it. In practice, indeed, we merely divide 180 by 15, multiply 13 by the 12, and set down 180 under 156 at once.

18. To *add* fractions, reduce them to others having a common denominator, then add the numerators of these, and write the common denominator under the sum. Thus, $\frac{5}{12}+\frac{1}{8}+\frac{7}{20}=\frac{50}{120}+\frac{15}{120}+\frac{42}{120}=\frac{107}{120}$. In each of the reduced fractions unity is divided into 120 equal parts, and the fractions are respectively equivalent to 50, 15, and 42 of these parts; therefore the sum of the fractions must be $50+15+42=107$ of them, *i.e.*, $\frac{107}{120}$.

Compound fractions must be reduced to simple ones before addition. Mixed numbers *may* be brought to improper fractions, and so added; but it is generally preferable to add the whole numbers and the fractions separately, and then add the two results. The operation may often be shortened by first adding any of the given fractions whose denominator is considerably less than that of all the fractions; thus, to add $\frac{25}{36}$, $\frac{13}{24}$, $\frac{33}{56}$, $\frac{36}{47}$, the sum of the first three may be found first, amounting to $1\frac{52}{63}$. The addition of $\frac{36}{47}$ to this gives $2\frac{1761}{2961}$.

19. To *subtract* fractions, reduce them to others having a common denominator, take the difference of the numerators so found, and write the common denominator under it. The principle is precisely the same as in addition.

Compound fractions must be simplified as in addition. With mixed numbers the subtraction will generally be best effected by treating the fractions separately, borrowing and carrying, if necessary, on the principle explained in § 5. In subtracting $47\frac{25}{28}$ from $85\frac{23}{36}$, for instance, borrowing $\frac{252}{252}$ and carrying 1 gives $85\frac{413}{252}-48\frac{225}{252}=37\frac{188}{252}$, or $37\frac{47}{63}$.

20. To *multiply* fractions, multiply the numerators together for the numerator of the product, and the denominators together for the denominator. Thus, in multiplying $\frac{5}{8}$ by $\frac{7}{9}$, if we multiply $\frac{5}{8}$ by 7, we have $\frac{35}{8}$ (§ 13); but our multiplier, $\frac{7}{9}$, is the ninth part of 7; we must therefore divide $\frac{35}{8}$ by 9, which gives $\frac{35}{72}$ (§ 13).

When there are several fractions to be multiplied continuously together, we proceed in the same way. Mixed numbers are reduced to improper fractions, and common factors may be struck out, precisely as in § 16. When an integer has to be multiplied by a fraction, we may convert the integer into a fraction by putting 1 as the denominator; or we may multiply the integer by the numerator of the fraction and divide by the denominator, since to multiply by $\frac{7}{9}$ is, as has just been shown, to multiply by 7 and divide by 9. So, to multiply an integer by a mixed number, the common method is to multiply by the integer and the fraction of the latter separately, and add the results. In multiplying mixed numbers like $46\frac{1}{4}$ and $14\frac{1}{3}$ together, instead of using improper fractions, we may take the four products 46×14, $\frac{1}{4} \times 14$, $46 \times \frac{1}{3}$, and $\frac{1}{4} \times \frac{1}{3}$, and add them. The amount is $644 + 3\frac{1}{2} + 15\frac{1}{3} + \frac{1}{12} = 662\frac{11}{12}$.

21. To *divide* fractions, invert the terms of the divisor (*i.e.*, interchange the positions of the numerator and denominator), and multiply the dividend by the inverted fraction; thus, $\frac{5}{8} \div \frac{7}{9} = \frac{5}{8} \times \frac{9}{7} = \frac{45}{56}$. If we divide $\frac{5}{8}$ by 7, we have $\frac{5}{56}$ (§ 13). But since our divisor, $\frac{7}{9}$, is the ninth part of 7, in dividing by 7 we divide by a number nine times too large. The true quotient must therefore be nine times $\frac{5}{56}$, *i.e.*, $\frac{45}{56}$.

The common method of dividing an integer by a mixed number is a modification of this division. When, in dividing by $37\frac{4}{5}$, for instance, we multiply both divisor and dividend by 5, and then divide, we really multiply the dividend by $\frac{5}{189}$. Or the method may be explained on the principle (identical with that of § 12) that the multiplication of the divisor and dividend by the same number does not affect the quotient. As an instance of the division of a mixed number by an integer, let $3982\frac{22}{35}$ be divided by 54. The quotient is 73, with remainder $40\frac{22}{35}$; and to obtain the complete quotient, this remainder must be divided by 54 (see § 11), giving $\frac{1422}{35} \times \frac{1}{54} = \frac{79}{105}$; *i.e.*, $73\frac{79}{105}$ is the result of the division.

A *complex fraction* is reduced to a *simple one* by dividing the numerator by the denominator; thus,

$$\frac{6\frac{5}{12}}{10\frac{1}{9}} = \frac{77}{12} \times \frac{9}{91} = \frac{33}{52}.$$

When one term only is fractional, it will be found convenient to multiply both terms of the complex fraction by the denominator that occurs in the fractional term; thus,

$$\frac{13\frac{3}{4}}{22} = \frac{13\frac{3}{4} \times 4}{22 \times 4} = \frac{55}{22 \times 4} = \frac{5}{8}.$$

Decimals.

Decimals.—22. In the ordinary denary notation, a figure in combination with others has only the tenth part of the value it would have if removed a place towards the left (§ 1); thus, in 374, the 3 signifies 3 times 100; the 7, 7 times 10; the 4, simply 4. By an extension of this notation we obtain a species of fractions that are often of very great use, especially for purposes of comparison. If we mark the place of units by a point put after it, and write other figures after the point, we can denote by the first of these figures one-tenth of the value it would have in the units' place; by the second, one-hundredth part, and so on. In 374·691, then, the 6 is 6 times $\frac{1}{10}$, *i.e.*, $\frac{6}{10}$; the 9, 9 times $\frac{1}{100}$, or $\frac{9}{100}$; and the 1, $\frac{1}{1000}$. Whence, by giving these fractions a common denominator and adding them, we have $374{\cdot}691 = 374\frac{691}{1000}$. These *decimal fractions* or *decimals*, therefore, are fractions of which the numerator only is written, the denominator being the continued product of as many tens as there are decimal figures.

In addition, subtraction, multiplication, and division of decimals, the operations are, and from the structure of decimals must be, the same as the like operations with integers. The position of the decimal point in the results is the only thing that needs particular explanation.

Results, it may be mentioned here, are often expressed by decimals that are not exact, but approximate only, it being held sufficient to give the correct value to some assigned number of decimal places. An amount correct to four decimal places differs from the true amount by less than the ten-thousandth part of unity. See above, p. 524

To reduce a decimal to a vulgar fraction, write the decimal as the numerator of the fraction, and set under it for the denominator 1 followed by as many ciphers as there are decimal places. This follows at once from the definition of a decimal.

To reduce a vulgar fraction to a decimal, annex ciphers to both terms of the fraction—the same number in both cases; divide both terms by the significant figures of the denominator, and then write the numerator as a decimal, pointing off as many decimal places (prefixing ciphers, if necessary) as there are ciphers in the denominator. (See also § 25, *infra.*) Thus, $\frac{3}{400} = \frac{300}{40000} = \frac{75}{10000} = {\cdot}0075$. Here the vulgar fractions retain their values unchanged (§ 12), and from the last the decimal is set down according to the definition.

It very often happens that in dividing as above we find there must always be a remainder. In this case, however, a remainder we had before may soon recur, giving the same figure or group of figures over and over again in the quotient; thus $\frac{17}{36}$ is found to be ·47222.....; $\frac{53}{925}$ is ·05729729...... The recurring figures are distinguished by points placed over them, the above results being written ${\cdot}47\dot{2}$ and ${\cdot}05\dot{7}2\dot{9}$. We shall return to the consideration of these recurring decimals at § 26.

23. To *add* or *subtract* decimals, write the numbers under each other, placing units under units, &c., add or subtract as with integers, and place the decimal point under the points in the given numbers. This follows directly from the definition of decimals.

24. To *multiply* decimals, multiply as with integers, and point off as many decimal places as there are in both factors taken together. Thus, in $37{\cdot}64 \times {\cdot}082 = 3{\cdot}08648$, the 4 and 2 in the factors are $\frac{4}{100}$ and $\frac{2}{1000}$, their product is therefore $\frac{8}{100000}$, *i.e.*, ·00008; and so with the others.

If an approximate product be sufficient, the multiplication may be shortened thus. Let it be required to find the product, say, of 4·273 and 6·859 correct to three places of decimals. Write the figures of the multiplier in reverse order, with the unit figure under the third decimal place of the multiplicand. Begin each multiplication with the figure above the multiplier, adding what has to be carried from the right hand figure, and observing to carry the *nearest* ten (*i.e.*, for 36, for instance, not 3, but 4); place the first figures of each multiplication under each other; then add and point off three decimal places. It will be seen that every figure of the product falls into its proper place, *e.g.*, the 8 and 7, the 5 and 2, &c., each give thousandth parts.

$$\begin{array}{r} 4273 \\ \underline{9586} \\ 25638 \\ 3418 \\ 214 \\ \underline{38} \\ 29{\cdot}308 \end{array}$$

25. To *divide* decimals, divide as with integers, and point off as many decimal places in the quotient as the dividend has more than the divisor. This follows from the dividend being the product of the divisor and quotient. *Exs.* $228{\cdot}956 \div 3{\cdot}64 = 62{\cdot}9$; $2{\cdot}28956 \div 36{\cdot}4 = {\cdot}0629$; $22895{\cdot}6 \div {\cdot}364 = 62900$. In the second example, the

dividend having five decimal places and the divisor one, the quotient must have four; a cipher is therefore prefixed to the three figures. In cases like the third example, where the dividend has fewer decimal places than the divisor, the number has to be made up in the former by ciphers, and as far as the end of the ciphers making up that number the quotient must be an integer. The quotient may be pointed at any stage after as many decimal places of the dividend have been made use of as there are in the divisor, the first figure after this being always the first decimal. This is especially to be attended to when the division does not terminate, or when a few figures only are required; thus, 63·94 divided by ·237 to two decimal places gives 269·79; 10 divided by ·264 gives 37·87.

The method of converting a vulgar fraction into a decimal, given in § 22, is in effect the division of the numerator by the denominator, the result being expressed as a decimal. Thus, $\frac{83}{160} = 83 \div 160 = \cdot 51875$.

When the quotient is required to a given number of places only (as three in the example), the operation may be shortened by dropping the last figure of the divisor at each successive multiplication. But this must not be commenced till the figures required in the quotient are fewer than the figures in the divisor, and the carriage from the dropped figure is to be added in each instance.

26. We have seen that the division by means of which vulgar fractions are converted into decimals (§§ 22, 25) will, in certain cases, always leave a remainder. If the fraction be in its lowest terms, there *must* always be a remainder whenever the denominator contains any other prime number as a factor besides 2 and 5. For in adding ciphers we multiply by tens, and we introduce no other factor. It often happens that we can speedily discover what the decimal must be, so as to be able to set down any number of figures without further actual division. Unless the division terminate, the same figures will recur sooner or later; and the same figures must recur before we use as many ciphers as there are units in the divisor. Supposing the divisor is 17, we can only have the numbers from 1 to 16 as remainders; the quotient must therefore repeat itself after all these remainders occur, if not earlier. All do occur in dividing by 17; thus,

$$\frac{2}{17} = \cdot\dot{1}17647058823529\dot{4}.$$

The fraction $\frac{5}{12}$ must always be greater than the decimal ·41666...., however far the latter be extended; but we can make the difference as small as we choose. Thus ·416666 does not differ from $\frac{5}{12}$ by the millionth part of a unit. The form of the decimal $\cdot 41\dot{6}$ is used to show that the 6 is to be considered as repeated continually; and this being understood, we can say that the decimal is *equal to* $\frac{5}{12}$.

Decimals of this kind are called *Recurring Decimals*. They are sometimes distinguished as *Repeating* or *Circulating Decimals*, according as one figure or more than one recur; and as *Pure* or *Mixed*, according as the recurring figures stand alone or are preceded by non-recurring decimals. Thus, $\cdot\dot{1}4\dot{8}$ is a pure circulating decimal; $\cdot 18\dot{3}$ is a mixed repeating one.

27. To reduce a recurring decimal to a vulgar fraction, subtract the decimal figures that do not recur from the whole decimal; set down the remainder as the numerator of the fraction, and as many nines as there are recurring figures, followed by as many ciphers as there are non-recurring figures, as the denominator.

The reason of proceeding in this way will appear if, taking any mixed recurring decimal, we multiply it by as many tens as there are decimal places, and again by as many tens as there are non-recurring decimals, and subtract the second product from the first. Take, *e.g.*, $\cdot 79\dot{0}5\dot{4}$:

$$100000 \text{ times } \cdot 79\dot{0}5\dot{4} = 79054\cdot 054054054\ldots.$$
$$\text{and} \quad 100 \text{ times } \cdot 79\dot{0}5\dot{4} = 79\cdot 054054054\ldots.$$
$$\text{therefore} \quad 99900 \text{ times } \cdot 79\dot{0}5\dot{4} = 78975$$
$$\text{whence } \cdot 79\dot{0}5\dot{4} = \tfrac{78975}{99900}, \text{ i.e., } \tfrac{117}{148}.$$

In the case of pure recurring decimals, we have no subtraction, and the denominator consists entirely of nines. Thus $\cdot\dot{3} = \frac{3}{9} = \frac{1}{3}$; $\cdot\dot{2}\dot{7} = \frac{27}{99} = \frac{3}{11}$.

28. In practical arithmetic recurring decimals are little used, except in approximations. They can be added or subtracted readily to any number of places by extending all a place or two beyond what is required. When we have to multiply or divide by recurring decimals, we must convert them into vulgar fractions. They may themselves be multiplied or divided by integers or ordinary decimals, though in this case, too, it is often better to use vulgar fractions, especially when exact results are desired.

Powers and roots.

Powers and Roots of Numbers.—29. When a given number is multiplied by itself, the product multiplied again by the number, and so on, the result obtained is called the second, third, fourth, &c., *power* of the number, according as it is the product of the number repeated two, three, four, &c., times. Thus, $7 \times 7 \times 7 = 343$ is the third power of 7; $5 \times 5 \times 5 \times 5 = 625$, the fourth power of 5. The term "square" is nearly always used instead of "second power" (*e.g.*, 81 is the square of 9), and "cube" frequently instead of "third power." The power to which a number is raised is indicated by a small figure written over the number to the right; thus, 8^5 is the fifth power of 8.

The *square root* of a given number is the number which, when multiplied by itself, produces the given number. And so, in general, whatever *power* one number is of another, the same *root* is the second of the first. Thus, 7 is the third root, or cube root, of 343; 5 is the fourth root of 625; 2 is the fifth root of 32. The sign $\surd$ (which is really an *r*, from *radix*, a root) prefixed to a number indicates a root of it. The simple sign stands for the square root; a figure is placed over it to denote other roots. Thus, $\surd 100$ is the square root of 100; $\sqrt[4]{256}$, the fourth root of 256.

Extraction of square root.

30. To extract the *square root* of a given number, divide it into periods of two figures, by putting a point over every second figure, commencing with that in the units' place; set down as the first figure of the root, the largest number whose square does not exceed the first or left-hand period; place the square of this number under the first period, and subtract it from it; to the remainder annex the next period; place before this as a trial divisor twice the root figure; consider how often the former (omitting the right-hand figure) contains the latter, and set down the number that expresses this as the next figure of the root; place also this root-figure to the right of the trial divisor; multiply by it the divisor thus completed; subtract the product from the number formed of the former remainder and the period taken down; add another period to the remainder now found; then double the whole root for a new trial divisor, and proceed as before.

```
      58̇21̇69̇(763
      49
      --
  146)921
      876
      ---
  1523)4569
       4569
       ----
```

The 58 of the example being 580000, the 49 must be 490000, and the root 700. So the 146 is 1460: the 921, 92100; the 6 is 60; and so on. This explains the principle of pointing in periods of two figures.

In place of doubling the whole root for every trial divisor, it will be sufficient to add to the preceding complete divisor its last figure; thus, $146 + 6 = 152$. The 7 has been already doubled in 14, and this doubles the 6.

The reason of proceeding as above will appear from the composition of an ordinary product. Thus, 23×23 is the sum of the four products 20×20, 3×20, 20×3, and 3×3, *i.e.*, 20^2, twice 20×3, and 3×3. Taking away, then, the square of 20, *i.e.*, 400, the remainder must be the sum of $2 \times 20 \times 3$, and 3×3, *i.e.*, 3 times the sum of 2×20 and 3, which we obtain by the method adopted.

If there is a remainder, ciphers may be taken down in pairs, and as many decimal places obtained as we please. In this case there must always be a remainder, since no unit multiplied by itself produces ciphers. After getting half the decimal places required, we may proceed by contracted division (§ 25).

To extract the square root of a vulgar fraction, we find the roots of the numerator and denominator separately. For, since $\frac{3}{4} \times \frac{3}{4} = \frac{9}{16}$, the square root of $\frac{9}{16}$ must be $\frac{3}{4}$. If either term of the fraction is not a complete square, it should be reduced to a decimal. Thus, $\sqrt{\frac{1}{2}} = \sqrt{\cdot 5} = \sqrt{\dot{0}\cdot\dot{5}0} = \cdot 7071067812$ nearly.

Extraction of cube root.

31. To extract the *cube root* of a given number, point off the number from the units' place into periods of three figures; write under the first period the greatest cube contained in it, subtract, and annex the next period to the remainder; then, regarding the root found as tens, multiply the square of it by 3 for a trial divisor, and divide by this for the next figure of the root; to the trial divisor add three times the product of the two root numbers (the first being tens), and also the square of the last root figure; multiply the sum by the last root figure; subtract the product from the number obtained by taking down last period; annex the next period to the remainder, and proceed as before.

For demonstration of the reason of this process, see ALGEBRA, vol. i. p. 528. It depends on the form of the product obtained in raising a number to its third power. Thus, $24 \times 24 \times 24$ is 24 times $20^2 + 2 \times 20 \times 4 + 4^2$, which will be found to be $20^3 + 3 \times 20^2 \times 4 + 3 \times 20 \times 4^2 + 4^3$. And this is 20^3 added to 4 times $3 \times 20^2 + 3 \times 20 \times 4 + 4^2$, which agrees with the process described above.

II. Practical Arithmetic.

32. Having explained in the foregoing sections the various operations of arithmetic, we now proceed to consider them in their combinations and practical applications. What has been said up to this point refers to numbers merely as numbers, or numbers in the abstract. Now they are to be regarded as applied to particular things, or representing particular magnitudes. Numbers so regarded are called *concrete;* and we now treat of *concrete* as distinguished from *abstract* arithmetic. Concrete numbers frequently represent not so much number as quantity. To form a distinct and accurate idea of 5 lb of tea bought for 15s., it is not necessary to think of the tea as divided into five portions, or as paid for with fifteen pieces of money.

It would be found extremely (indeed intolerably) inconvenient to have to make all payments, great and small, by means of one particular species of coin, or to serve out all quantities of goods, using only one kind of weight or measurement. Various monies, weights, and measures are therefore in customary use, this or that being employed in each particular case according to circumstances. When these measures are of the same kind, differing only in the unit of one of them being so many times the unit of another, they are said to be of different *denominations;* as, pounds, shillings, pence; or again, yards, feet, inches.

In addition and subtraction, the quantities added and subtracted must be either abstract numbers or concrete quantities of the same kind. In multiplication, the multiplicand may be concrete, but the multiplier is regarded in the process as abstract. If 20 men, for example, receive £5 each, the £5 is not multiplied by 20 *men*, but taken 20 *times*, the number of times merely corresponding to the number of men. In division, when the dividend is concrete, the divisor may be abstract, giving a concrete quotient of the same kind as the dividend, or concrete giving an abstract quotient. Thus, £100 may be divided into 20 parts, giving £5 as quotient, or it may be divided into parts of £5 each, giving as quotient the abstract number 20, *i.e.*, containing £5 20 times. A fraction is strictly abstract, though we often write £$\frac{5}{9}$ and the like for $\frac{5}{9}$ of £1.

33. The following are the tables of monies, weights, and measures in common use:—[1] Tables.

I. *Money.*

4 farthings	=	1 penny, *d.*
12 pence	=	1 shilling, *s.*
20 shillings	=	1 pound, £ or *l.*

II. *Avoirdupois Weight.*

16 drams, *drs.*	=	1 ounce, *oz.*
16 ounces	=	1 pound, *lb.*
28 pounds	=	1 quarter, *qr.*
4 quarters	=	1 hundred-weight, *cwt.*
20 hundredweights	=	1 ton.

III. *Troy Weight.*

24 grains, *grs.*	=	1 penny-weight, *dwt.*
20 pennyweights	=	1 ounce, *oz.*
12 ounces	=	1 pound, *lb.*

IV. *Length.*

12 inches, *in.*	=	1 foot, *ft.*
3 feet	=	1 yard, *yd.*
5½ yards	=	1 pole or perch, *po.*
40 poles	=	1 furlong, *fur.*
8 furlongs	=	1 mile, *mi.*

V. *Surface.*

144 square inches	=	1 square foot.
9 sq. feet	=	1 sq. yard.
30¼ sq. yards	=	1 sq. pole.
40 sq. poles	=	1 rood, *ro.*
4 roods	=	1 acre, *ac.*

VI. *Solidity.*

1728 cubic inches	=	1 cubic foot.
27 cubic feet	=	1 cubic yard.

VII. *Capacity.*

4 gills	=	1 pint, *pt.*
2 pints	=	1 quart, *qt.*
4 quarts	=	1 gallon, *gal.*
2 gallons	=	1 peck, *pk.*
4 pecks	=	1 bushel, *bus.*
8 bushels	=	1 quarter, *qr.*

VIII. *Time.*

60 seconds, *s.*	=	1 minute, *m.*
60 minutes	=	1 hour, *hr.*
24 hours	=	1 day.
365 days	=	1 year, *yr.*

On these tables we make the following remarks:—

I. The guinea is 21 shillings, and the crown 5 shillings. Sales are often made in guineas, though the coin is not now used. Farthings are always written as fractions of a penny. $10\frac{3}{4}d.\ \frac{7}{8}q.$ means tenpence three farthings and seven-eighths of a farthing.

III. *Apothecaries' weight* agrees with this, except that the ounce (℥) is divided into 8 drams (ʒ), and the dram into 3 scruples (℈) of 20 grains.

[1] By an Act of Parliament, passed in 1824, the imperial standard weights and measures are connected in the following way with the *mean solar day*, the length of which is fixed invariably:—The *yard of* 36 inches is determined from the length of a pendulum, vibrating once in a second, which, in the latitude of London, is 39·13929 inches; the *pound troy* of 5760 grains, from a cubic inch of distilled water, weighing 252·458 grains; and the *gallon* as being the space occupied by 10 lb avoirdupois (*i.e.*, 70,000 grains troy) of distilled water, equivalent to 277·274 cubic inches,—all these verifications being made with thermometer at 62° Fahr. and barometer at 30 inches.

IV. In measuring cloth, the yard is divided into 4 quarters, the quarter into 4 nails of $2\frac{1}{4}$ inches.

V. To measure land, the surveyor's chain of 100 links is used. The chain is 22 yards long, and 10 square chains make an acre.

VII. The gallon and lower denominations are liquid measures; the quart and those above it are for dry goods.

VIII. The year, strictly speaking, is 365·24224 days. Every fourth year (leap year) has 366 days.

34. *Reduction* is the method of expressing quantities in a denomination lower or higher than that in which they are given.

To reduce a higher denomination to a lower, multiply in succession by the numbers which show the times that the unit of each denomination (beginning with that given) contains the unit of the one next below it till the denomination is reached to which the quantity is to be reduced. If quantities in intermediate denominations are given, add each as its denomination is reached.

To reduce a lower denomination to a higher, divide in succession by the numbers which show the times that the unit of each denomination (beginning with that given) is contained in the unit of the next above it, observing that the remainder after such division is of the denomination of the dividend.

Sometimes the two processes are combined; thus, in reducing guineas to crowns, we multiply by 21, obtaining shillings, and then divide by 5.

35. *Compound Addition* and *Compound Subtraction* are the addition and subtraction of quantities expressed in more than one denomination.

Compound addition. In Compound Addition, arrange the quantities according to their denominations, each under its proper heading; add the lowest, and reduce the sum by division to the next higher, setting down the remainder, and carrying the quotient; add the others, including carriage, in the same way. Suppose that several sums of money are added, and the farthings amount to 29, that is to $7\frac{1}{4}$d., the $\frac{1}{4}$d. is set down and the 7d. carried to the pence column, and so in other cases.

Compound subtraction. In Compound Subtraction, arrange the quantities as in Compound Addition, placing the greater amount over the other, and subtract, beginning with the lowest denomination. If in any case the lower number exceeds that above it, increase the latter by as many as make one of the next higher denomination, and afterwards add one to that denomination in the lower line. In subtracting, *e.g.*, 1 qr. 25 lb from 3 qr. 17 lb, since 25 cannot be taken from 17, a quarter, *i.e.*, 28 lb, is added to the 17, making 45; from this 25 is subtracted, leaving 20 lb, and the quarter "borrowed" is taken away again by being added to the 1 qr. The remainder is thus 1 qr. 20 lb.

Fractions of the lowest denomination are to be added or subtracted according to §§ 18, 19; thus, £72, 8s. $3\frac{9}{14}$d. − £45, 17s. $6\frac{17}{21}$d. = £26, 10s. $8\frac{5}{6}$d.

Compound multiplication. 36. *Compound Multiplication* is multiplication in which the multiplicand is expressed in more than one denomination.

When the multiplier does not exceed 12, multiply the different denominations by it, beginning with the lowest, and setting down and carrying as in Compound Addition. When the multiplier consists of several figures, multiply by each separately in the same way, taking them from right to left, and setting the result of each successive multiplication always one place further towards the left in each denomination, and add the results as thus arranged. In the accompanying example the above arrangement puts the product by 90 in the place of tens; and the sums to be reduced to higher denominations are 30 farthings, 104 pence, 148 shillings. If the multiplier be a composite number, we may multiply by the factors in succession. When the multiplier consists of two or more figures, the multiplication is often performed by the whole quantity at once.

£63	12	$7\frac{3}{4}$	
		94	
254	10	$7\frac{0}{4}$	= 4 times.
572	13	$9\frac{3}{4}$	= 90 times.
£5981	8	$8\frac{1}{2}$	= 94 times.

37. *Compound Division* is division in which either the dividend or both dividend and divisor are expressed in more than one denomination. Compound division.

(1.) To find the amount that a given amount contains a given number of times, divide the highest denomination by the given number, reduce the remainder to the next lower denomination, adding the corresponding term of the dividend; divide again, and proceed in the same way with the other denominations. The denominations of the quotient correspond to those of the dividend.

Let it be required, for instance, to divide £370, 16s. $1\frac{3}{4}$d. into 58 equal shares. As 58 shares of £6 each amount to £348, £6 is part of the quotient, and there remains £22, 16s. $1\frac{3}{4}$d. Reducing £22, 16s. to shillings (456), we find that this gives 58 shares of 7s. each, with 50s. over. Similarly we obtain 10d. and 1 farthing, with 29 farthings over, which, since $\frac{29}{58}=\frac{1}{2}$, is just half a farthing for each of the 58 shares. The quotient then is £6, 7s. $10\frac{1}{4}$d. $\frac{1}{2}$q.

(2.) To find the number of times that one given amount contains another, reduce both to the same single denomination, and then divide the one by the other.

To find, for example, how often 12s. $9\frac{3}{4}$d. is contained in £171, 13s. 9d., since 12s. $9\frac{3}{4}$d. = 615 farthings, and £171, 13s. 9d. = 164820 farthings, the number of times the second amount contains the first must be 164820 ÷ 615, *i.e.*, 268. It is to be observed that the quotient here is an abstract number.

38. In multiplying or dividing by fractions or mixed numbers, we follow the methods explained in §§ 20, 21. As an illustration, we give here the multiplication of £24, 5s. $9\frac{1}{2}$d. $\frac{6}{7}$q. by $62\frac{5}{12}$, where we may note that in the division by 12 we have to divide $2\frac{2}{7}$ farthings, giving $\frac{16}{7}$q. × $\frac{1}{12}=\frac{4}{21}$q., and that in adding the fraction we have $\frac{15}{7}+\frac{4}{21}=2\frac{3}{21}+\frac{4}{21}=2\frac{1}{3}$q.

	£24	5	$9\frac{1}{2}$	$\frac{6}{7}$
			$62\frac{5}{12}$	
12)	121	9	$0\frac{1}{2}$	$\frac{2}{7}$
	10	2	$5\frac{0}{4}$	$\frac{4}{21}$
	48	11	$7\frac{1}{4}$	$\frac{5}{7}$
	145	14	$10\frac{1}{4}$	$\frac{1}{7}$
	£1516	2	$7\frac{1}{4}$	$\frac{1}{3}$

39. *Reduction of Fractions and Decimals.*—To find the proper value of a fraction or a decimal of any denomination, multiply the fraction or the decimal by the numbers in succession that reduce the denomination to lower denominations. Reduction of fractions.

Thus, to find the value of $\frac{59}{96}$ of a pound, it is manifest that this is $\frac{59}{96}$ of 20 shillings, *i.e.*, $\frac{59}{96}\times 20$s. = $12\frac{7}{24}$s., or 12s. $3\frac{1}{2}$d.; and so in other cases.

To find the value of a fraction of a quantity consisting of different denominations, we may either first reduce the quantity to one denomination, or we may multiply the compound quantity by the numerator, and divide by the denominator of the fraction; thus, $\frac{2}{9}$ of £5, 7s. $11\frac{1}{4}$d. being the same as the ninth part of twice the amount, we may multiply by 2 and divide by 9, obtaining £1, 3s. $11\frac{3}{4}$d. $\frac{1}{3}$q. as the result.

40. To reduce any amount to the fraction or the decimal of another denomination or amount, reduce both amounts to the same denomination, and write them as the terms of a fraction, the quantity of which the fraction is required being made the denominator. If the decimal is required, convert the vulgar fraction into a decimal.

Thus, to reduce 13s. $1\frac{1}{2}$d. to the fraction and also to the decimal of a pound, since a pound contains 480 halfpence, a halfpenny is $\frac{1}{480}$ of a pound, and therefore 13s. $1\frac{1}{2}$d., *i.e.*, 315 halfpence, is £$\frac{315}{480}$ = £$\frac{21}{32}$ = £·65625.

It is often sufficient to throw the expressions into the reduced form, without actually performing the reduction, and divide the numerator of the complex fraction so obtained by the denominator. Thus, to find the fraction of £$46\frac{31}{50}$ that $\frac{3}{4}$ of $46\frac{2}{5}$ guineas is, both terms may be expressed as shillings,—$\frac{3}{4} \times \frac{232}{5} \times \frac{21}{1}$, and $\frac{2331}{50} \times \frac{20}{1}$; whence, dividing the former by the latter, the required fraction is found to be $\frac{29}{37}$.

In reducing a compound quantity to a decimal of a higher denomination, it is generally best to proceed by successive divisions, beginning with the lowest denomination, and inserting the others as they occur, as in the accompanying example, where 13 cwt. 8 ℔ 12 oz. is found to be ·65390625 of a ton. It is to be noted that the integers here are inserted from the data, and the decimals obtained by division. The form, though somewhat incongruous, is convenient.

```
   16) 12 oz.
   28)  8·75 ℔.
    4)   ·3125 qrs.
  2,0)1,3·078125 cwt.
         ·65390625 tons.
```

Practice. 41. *Practice* is the name given to a method of calculating prices from certain rates being *aliquot parts* (that is, exact measures) of other rates.

The basis of this species of calculation is generally £1, and the given price is broken up into portions, the first of which is an aliquot part of a pound, and each of the others an aliquot part of some one before it. By the method adopted we virtually multiply the different aliquot parts in succession by the number of articles given. The sum of the result is the total price.

Proportion 42. *Proportion.*—When the first of four quantities is the same multiple or the same fraction of the second that the third is of the fourth, the first is said to have the same *ratio* to the second that the third has to the fourth, and the four quantities are said to be *proportionals*, or *in proportion.* Thus, since 30 is $\frac{5}{6}$ of 36, and 50 is $\frac{5}{6}$ of 60, the numbers 30, 36, 50, and 60 form a proportion.

The proportion is written $30 : 36 = 50 : 60$, or, more commonly, $30 : 36 :: 50 : 60$. This is read 30 is to 36 as 50 is to 60. It may also be written $\frac{30}{36} = \frac{50}{60}$.

The ratio of two numbers is thus equivalent to the fraction that the one is of the other; and a fraction may therefore be defined as the ratio of the numerator to the denominator.

Ratio is a mere abstract relation between two numbers, or between two concrete quantities of the same kind. The ratio of 4s. to 6s., or of 48d. to 72d., is not shillings or pence, but the abstract fraction $\frac{2}{3}$.

If two quantities of one kind be proportional to two of another kind, when any three are given, the fourth can be found. If, for instance, we know the value of any quantity of goods, we can determine the value of any other given quantity, or the quantity that has any assigned value, —it being always understood that the rate is the same in both cases; that is, that were the quantity doubled, trebled, halved, &c., so also would the value be, or, in other words, that the quantity is proportional to the value. Questions of this sort occur with very great frequency in practical arithmetic. The three quantities given are usually arranged as the first three terms of a proportion, whence the fourth term is found.

The rule by which we proceed in such cases of *Simple Proportion*, as it is called, has often the name given to it of the *Rule of Three.* It is as follows:—Of the three quantities given, set that down for the third term which is of the same kind as what is required. Consider whether the amount to be found will be greater or less than this third term; if greater, make the greater of the two remaining quantities the second term, and the other the first term; but if less, put the less term second, and the greater first. Having thus arranged or "stated" the three terms of the proportion, multiply the second and third together, and divide the product by the first.

The first and second terms must be reduced to the same denomination, and it will often be convenient to reduce the third term to the lowest denomination contained in it.

Ex. 1. If 54 yards of cloth cost 63s., what will 30 yards cost at the same rate?

Stating by the rule, we have 54 yards : 30 yards :: 63s., whence the fourth term is $\frac{30 \times 63}{54} = 35$s.

This process is to be explained by the consideration that, since the rate of price is the same for both quantities, the one price must be the same fraction of the other that the one quantity is of the other; that is, $\frac{54 \text{ yds}}{30 \text{ yds.}} = \frac{63\text{s}}{\text{the price required}}$, or $\frac{30}{54} = \frac{\text{the number of shillings required}}{63\text{s.}}$ Multiplying each of these equal fractions by 63, we have $\frac{30}{54} \times 63 = 35$, the number of shillings required, as above.

The first and second terms are to be stated according to the rule, because their ratio is equal to that of the third and fourth, and must therefore be a proper or an improper fraction, according as the other is so. After the proportion is stated, and the terms reduced, any common factor may be removed from the first and second terms, or from the first and third; for, as will appear from the working above, this is virtually reducing a fractional expression to lower terms.

Ex. 2. A bankrupt, whose debts amount to £1275, pays 14s. 6d. in the pound. What do his creditors lose?

Since 14s. 6d. is paid, there is 5s. 6d. loss for every pound of debt, and the question is—If £1 give 5s 6d. loss, what will £1275 give? The "stating," therefore, is— £1 : £1275 :: 5s. 6d., and the result, £350, 12s. 6d. Particular care must be taken, when all the terms are money, as here, that the first and second be of the same kind. In this instance these terms are *debt;* and the third term, *loss*, corresponds to the term required.

Ex. 3. If 91 men could perform a piece of work in 78 days, in what time could 21 men do it, working at the same rate?

Here, if the number of men were doubled, trebled, halved, &c., the time required would be one-half, one-third, double, &c., the given time; or as the former is increased the latter is diminished in the same proportion, and *vice versa.* The time in this case is said to be *inversely proportional* to the number of men. We have then as equal ratios $\frac{21 \text{ men}}{91 \text{ men}} = \frac{78 \text{ days}}{\text{days required}}$; that is, the "stating" of the proportion is 21 men : 91 men :: 78 days, according to the rule, and the result 338 days. The process may also be explained thus:—The work will be 91×78 times what 1 man can do in 1 day, or $\frac{91 \times 78}{21}$ times what 21 men can do in 1 day, *i.e.*, it will be $\frac{91 \times 78}{21}$ days' work for 21 men.

43. *Compound Proportion.*—The ratio of two quantities frequently depends on a combination of other ratios. If, for instance, we have to compare the times required for building two walls, one twice the length, twice the height, and twice the thickness of the other, the men employed on the former being half the number employed on the other, and the day half the length, each of these separate conditions implies double the number of days. Each condition gives the ratio 1 : 2, and the result must correspond to the *product* of all the ratios, that is, it is 1 : 32. This is an instance of what is called compound proportion. Compound proportion.

In such cases set down for the third term the quantity which is of the same kind as that required. State each proportion as though it alone had to be considered, writing them under each other. Multiply the product of all the second terms by the third term, and divide the result by the product of the first terms.

Ex. If 36 men, working 10 hours a day, perform three-fifths of a piece of work in 17 days, how long must 25 men work daily to do the rest of it in 16 days?

Men,	25 : 36 :: 10
Fifths of the work,	3 : 2
Days,	16 : 17

$$\frac{36 \times 2 \times 17 \times 10}{25 \times 3 \times 16} = \frac{51}{5} = 10\tfrac{1}{5} \text{ hours a day.}$$

The length of the day will be greater the fewer the men and the fewer the days are, and less the less the work is; we therefore state as above.

44. It not unfrequently happens that ratios have to be compounded, or other reductions made, before we can state the proportion which will give the required result. We give an example or two of this.

Ex. 1. Though the length of my field is one-seventh greater than that of my neighbour's, and its quality is one-ninth better, yet, as the breadth of mine is one-fourth less, his is worth five guineas more than mine. What is my field worth?

The length of his field is to that of mine as 1 to $1\frac{1}{7}$, *i.e.*, as 7 to 8. The other ratios are 9 : 10 and 4 : 3 (see § 16 *ad fin.*). Therefore the values of the fields are as $7 \times 9 \times 4$ to $8 \times 10 \times 3$, *i.e.*, as 21 to 20, and the difference of these values being £5, 5s., we have the proportion 1 : 20 :: £5, 5s., which gives £105 as the worth of my field.

Ex. 2. If 9 men or 15 women, working 10 hours a day, could reap a field in 8 days 6 hours, in how many days of $10\frac{1}{2}$ hours each could 10 men and 12 women reap a field one-fourth larger?

Since 15 women do as much as 9 men do in the same time, 12 women will do $7\frac{1}{5}$ times a man's work, for $15 : 12 :: 9 : 7\frac{1}{5}$. Therefore 10 men and 12 women will do $17\frac{1}{5}$ times a man's work. From this the stating in the margin follows. The result is $56\frac{1}{4}$ hours, *i.e.*, 5 days $3\frac{3}{4}$ hours, the day being $10\frac{1}{2}$ hours long.

$$17\tfrac{1}{5} : 9 :: 86 \text{ hrs.}$$
$$4 : 5$$

Ex. 3. A dealer who has bought 9 oxen and 5 sheep for £186, 2s. 6d., would lose £2 by exchanging 2 oxen for 11 sheep. What is the price of an ox?

The price of 2 oxen being the price of 11 sheep and £2 more, the price of 9 oxen will be (from the ratio 2 : 9) $49\frac{1}{2}$ times the price of a sheep and £9 more. Hence from the data, $54\frac{1}{2}$ times the price of a sheep and £9 more will amount to £186, 2s. 6d.; *i.e.*, $54\frac{1}{2}$ times the price of a sheep is £177, 2s. 6d., and therefore a sheep cost £3, 5s. Also, since the price of 2 oxen is that of 11 sheep and £2 more, 2 oxen cost £35, 15s. + £2, *i.e.*, £37, 15s.; therefore 1 ox cost £18, 17s. 6d.

Proportional parts. 45. *Proportional Parts.*—To divide a number or quantity into parts in proportion to given numbers, state and work out the proportions,—As the sum of the given numbers is to each of them in succession, so is the number to be divided to the several parts required.

If, for example, a bankrupt owes A £580, B £935, C £675, and D £770, and his assets amount to £999, the stating 2960 : 580 : £999 gives £195, 15s. as A's share, and the others are found similarly.

Here, too, there may be a compound proportion, as when different sums are invested for different times. The division in those cases must be in proportion to the amounts invested, and also to the time; each amount is therefore to be multiplied by its time.

Applications of Proportion.—46. In commercial and financial transactions frequent use is made of proportion; and very often, when it is not directly employed, computations are performed according to formulæ or rules which rest on this as a basis. Advantage is very generally taken of the convenience of 100 as a standard of reference or comparison, proportional relations being stated as at such and such rates per cent. This occurs continually in the calculation of interest, discount, stock-exchange operations, &c., as well as in the expression of mercantile losses and gains.

47. *Interest* is the allowance given by the borrower to the lender for the use of money lent. It is usually computed at a rate agreed upon of so many pounds for every hundred lent for a year; this is called the *rate per cent.* The interest of £564, for instance, for 3 years 4 months at $3\frac{3}{4}$ per cent. per annum, is to be found by a compound proportion, the meaning being—If the interest of £100 for 1 year be £$3\frac{3}{4}$, what will the interest of £564 be for $3\frac{1}{3}$ years? The result (£70, 10s.) may be obtained by the general rule based on this and similar proportions—Multiply the amount lent (called the *principal*) by the rate per cent. and by the number of years, and divide the product by 100. When the time is given in days, the fraction of a year is taken that the days amount to. Interest.

$$£100 : 564 :: 3\tfrac{3}{4}$$
$$1 : 3\tfrac{1}{3}$$

Money is laid out at *Compound Interest*, when at the end of a year or other assigned period the interest that has accrued is not paid to the lender, but is put to interest along with the amount originally lent. Here the simple interest has to be computed for each successive year or period, and added to the principal or former amount.

48. *Commission* is the allowance paid to an agent for transacting commercial business, and usually bears a fixed proportion or percentage, as may be agreed on, to the amount of value involved in the transactions. *Brokerage* is the allowance paid to a broker for buying or selling shares in the public funds, or bargaining otherwise with reference to money investments. *Insurance Premiums* are payments in return for which the owner of the property insured is entitled to receive the assured value of it in the event of its being destroyed. In all these the rates are commonly stated at so much per cent., and the computation is similar to that for interest, but simpler, as the element of time does not enter into it. Commission. Brokerage. Insurance.

49. *Discount* is a deduction allowed for a payment being made at a date prior to the time when the full amount is exigible. The *true discount* on a money payment due on the expiration of a certain time is the excess of the amount over its *present value*—the present value being the sum which, laid out at interest, would in the given time amount to the given sum. Suppose, for instance, it is required to find the true discount on £664 due 10 months hence at $4\frac{1}{2}$ per cent. Here the interest of £100, being £$4\frac{1}{2}$ in 12 months, will in 10 months be £$3\frac{3}{4}$, *i.e.*, £100 would amount to £$103\frac{3}{4}$ in 10 months, and the discount of £$103\frac{3}{4}$ due 10 months hence is therefore £$3\frac{3}{4}$. Hence the stating £$103\frac{3}{4}$: £664 :: £$3\frac{3}{4}$, which gives as the discount £24. The present value is seen from this to be £640. A banker or merchant, in discounting a bill, charges interest instead of discount, and would in this instance gain the interest of £24, since the £24, the true *discount* of £664, is evidently the *interest* of £640. Discount.

50. In calculations relating to mercantile *Profit and Loss*, which are also effected by proportion, it must be carefully remembered that the percentage of gain or loss is always reckoned on the *buying price*, unless the contrary is expressly stated. Thus, let it be required to find the cost of goods that are sold for £448, 17s. 6d. at a loss of $6\frac{1}{4}$ per cent. Since goods that cost £100 are sold for £$93\frac{3}{4}$, we have the stating £$93\frac{3}{4}$: £$448\frac{7}{8}$ :: £100, which gives £478, 16s. as the cost price. Profit and loss.

(G. M'A.)

ARIUS (Ἄρειος), a well-known name in ecclesiastical history, identified with the origin and spread of the first great "heresy" in the Christian church. Arius is supposed to have been a native of Cyrenaica in Africa, but nothing is really known of his birth or of his early training. He first comes clearly into view as a presbyter of the Church of Alexandria, in the commencement of the 4th century, engaged in conflict with his bishop, Alexander. At a previous period he is said to have been connected with the Meletian schism, and on this account to have been excommunicated by Peter of Alexandria, who had ordained him deacon. But if so, he had regained a position of importance in the Alexandrian Church, as he is found, under Peter's successor, Achillas, in charge of one of the great city churches, Baucalis or Boucalis, where he continued to discharge his duties with apparent faithfulness and industry for six years after the accession of Alexander, the third bishop in order with which ecclesiastical tradition connects him. Theodoret (*Hist. Eccl.*, i. 2) does not hesitate to say that Arius was chagrined because Alexander, instead of himself, was appointed to succeed Achillas in the see of Alexandria, and that the beginning of his heretical attitude is, in consequence, to be attributed to discontent and envy. But this is so common an explanation of heretical movements with the early church historians, that it is not to be received without reserve. Upon the whole, there is no evidence that Arius was animated by mere personal considerations in the advocacy of his doctrinal opinions. Rather, it seems evident, as Neander says (*Church Hist.*, vol. iv. 25), that he thought he was only unfolding the traditionary church doctrine. Although an African he appears to have been trained in the school of Antioch, under Lucian, and there to have imbibed a strong leaning towards the subordination system as to the relation of the Father and Son, which prevailed in that school. Probably it was this training, and a natural lack of insight and speculative depth, which led him into a line of negative thought, from which the church had hitherto wisely abstained. Yet the idea of his craft and ambition deeply pervades early Christian history. In his well-known treatise against eighty heresies (*Lib. II. Hær.*, lxix. c. 3), Epiphanius describes him as a man "inflamed by his own opinionativeness; of tall stature, with a downcast look; his figure composed like that of a subtle serpent, to deceive the guileless by his crafty exterior." "His dress," he adds, "was simple; his address soft and smooth, calculated to persuade and attract, so that he had drawn away seven hundred virgins from the church to his party."

The views of Arius first attracted attention about 319 A.D. According to the church historian Socrates (lib. i. c. 5), Bishop Alexander, in addressing the presbyters and other clergy on the doctrine of the Trinity, dwelt so strongly on the consubstantial unity of the Father and the Son that Arius charged him with holding Sabellianism. But, according to Sozomen, a contemporary historian of the 5th century, Arius made himself conspicuous by the advocacy of his special opinions, and Alexander only interfered after being charged with remissness in leaving him so long to disturb the faith of the church. Having called Arius and his opponents before him, Alexander heard their respective arguments, and finally, after due examination, gave judgment against Arius. The result was a wide-spread commotion, extending not only through Africa, but other provinces of the Roman empire. Bishops joined issue with bishops; congregations were violently excited; and the greatest mystery of the Christian religion became a subject of irreverent controversy among women and children. Even the heathen joined in the profane uproar. Arius himself cannot be excused from stirring up this popular and unworthy clamour; for he composed verses, under the name of Thalia (Θαλεία), which appear to have been a sort of popular miscellany for diffusing his opinions. He addressed at the same time an elaborate letter to Eusebius of Nicomedia, which remains to this day one of the clearest statements of his dogmatic position. It sets out with a complaint of the persecution which he had suffered at the hands of Alexander, who had driven him and his adherents (he says) out of the city as impious men or atheists (ἀθέους), "merely for dissenting from his public declaration that 'as God is eternal so is His Son'—when the Father, then the Son—the Son is present in God without a birth (ἀγεννήτως), ever begotten (ἀειγενής), an unbegotten-begotten (ἀγεννητογενής);—an eternal God, an eternal Son; the Son is from God himself." . . . . "These blasphemies we cannot bear to hear even," he says, "no, not if the heretics should threaten us with ten thousand deaths. What, on the other hand, do we maintain? that the Son is not unoriginate (ἀγέννητος), nor part of the Unoriginate, nor made of any previously existing substance, but that by the will and purpose of God He was in being before time (πρὸ χρόνων καὶ πρὸ αἰώνων), perfect God, the only begotten (πλήρης Θεὸς, μονογενής); that before this generation or creation He was not (πρὶν γεννηθῇ . . . . οὐκ ἦν)," &c.

There is another letter to the same purpose, but more moderate in statement, addressed to Alexander after his banishment; and the student will find in those letters, and in the Thalia, the most original and trustworthy account of the opinions of Arius. "We believe," he says in the letter to Alexander, "in one God alone without birth, alone everlasting, alone unoriginate . . . . We believe that this God gave birth to the only begotten Son before eternal periods (πρὸ χρόνων αἰωνίων), through whom He made these periods (αἰῶνας) and all things else; that He gave birth to Him, not in semblance, but in truth, giving Him a real existence (ὑποστήσαντα), at His own will so as to be unchangeable, God's perfect creature, but not as other creatures . . . . not, as Valentinus (a Gnostic of the 2d century) maintained, a development (προβολήν); nor, again, as Manichæus, a consubstantial part (μέρος ὁμοούσιον); nor as Sabellius, Son and Father at once (υἱοπάτερα), which is to make two out of one, . . . but created by the will of God, and endowed with His own glorious perfections—yet not so that the Father did thereby deprive himself of attributes which are His without origination (ἀγεννήτως), being the Source (πηγή) of all things; so that while there are three persons (ὑποστάσεις) yet God is alone the Cause of all things and unoriginate. The Son, on the other hand, is originate, begotten by the Father time-apart. The Son is not, therefore, co-eternal or co-unbegotten with the Father, as if these were two unbegotten principles; but God is before all things as (μονάς) single and the principle of all, and therefore before Christ also."

On the one side, therefore, Arius denied of Christ that He was *unoriginate;* or part of the Unoriginate; or consubstantial (ὁμοούσιον) with the Father; or without beginning (ἄναρχος); or a mere development of God. The Son, he said, "did not exist before He was begotten (οὐκ ἦν πρὶν γεννηθῇ)." In other words, "He is of a substance that once was not (ἐξ οὐκ ὄντων),"—hence the name of *Exoucontians* sometimes given to his followers. But, on the other side, Arius affirmed of the Son that He was in being before time (προχρόνων); that he was perfect God (πλήρης Θεός); only begotten (μονογενής); that God made the worlds or ages (αἰῶνας) through Him; that He was the making or offspring of the Father, and yet not as one amongst things made (γέννημα ἀλλ' οὐχ ὡς ἓν τῶν γεγεννημένων).

Such were the questions which distracted the church beyond all precedent in the beginning of the 4th century, and led to the first great œcumenical council, which was convened in Nicæa in 325. The account of the proceedings of this council will be given under its own heading. It requires only to be mentioned here, that after various turns in the controversy, it was finally decided against Arius, that the Son was "of the same substance" (ὁμοούσιον) with the Father, "very God of very God." Constantine embraced the decision of the council, and resolved to uphold it. Arius and the two bishops of Marmarica and Ptolemais, who refused to subscribe the creed of Nicæa, were excommunicated and banished to Illyria; and even Eusebius of Nicomedia, who accepted the creed, but not its anathemas, was exiled to Gaul. Alexander returned to his see triumphant, but died soon after, and was succeeded by Athanasius, his deacon, who had been the soul of the orthodox party of Nicæa, and with whose indomitable fortitude and strange vicissitudes the further course of the controversy is bound up. This will be explained in detail under the heading ATHANASIUS, and it only remains for us to sketch at present what is known of the future career of Arius.

Although defeated at the Council of Nicæa, Arius was by no means subdued. He obtained means of access to Constantia, the sister of the emperor, who, on her deathbed, strongly urged her brother to reconsider the question, and to recall the heresiarch from banishment. Restored to court, he, along with the Eusebian party, who, although professing to accept the Nicene doctrine, were in reality indifferent, if not hostile, to it, renewed the theological strife, in which Athanasius was nothing loth to join. Interchanges, now of friendly recognition and now of menace, passed betwixt the emperor and the intrepid bishop of Alexandria, who obstinately refused to reinstate Arius as presbyter. At length, on the banishment of Athanasius to Treves in 336, Arius returned to Alexandria to claim his old position; but even in the absence of the bishop the people rose in uproar against the heretic, and the emperor was forced to recall him to Constantinople. There the bishop was reluctantly compelled to profess his willingness to receive him once more into the bosom of the church, but before the act of admission was completed Arius was taken suddenly ill, while walking with a friend in the evening, and died in a few moments. This was interprêted by the adherents of the Nicene theology as a special interposition of Providence on their behalf, and they openly gave thanks to God in the church. The modern reader will look with less credulity upon an event which was probably quite natural in its occurrence, but he will hardly see any cause in it for lamentation. The character of Arius, if not originally tainted by self-seeking and restless ambition, appears to have gathered something of this taint in the course of his career, and the most impartial student of church history fails to see anything in it to admire beyond the pertinacity of his courage and his faithful devotion to his own opinions.

The Followers of Arius.—The death of Arius, as described above, did not extinguish the Arian party. On the contrary, they continued active and zealous *within* the church for upwards of fifty years, or till the second general council at Constantinople, in 381. Afterwards they may be said to have existed, as a distinct Christian sect, outside the Catholic Church, till about the middle of the 7th century. Constantine, while strongly disposed at first to enforce the Nicene decrees, was gradually won to a more conciliatory policy by the influence especially of Eusebius of Cæsarea, and his namesake, Eusebius of Nicomedia. On the other hand, the Nicene doctrine found the most able and ardent defender in Athanasius, the young deacon who had attended Bishop Alexander at the council, and who shortly afterwards succeeded him in the see of Alexandria. An unceasing contention ensued betwixt the Eusebian and Athanasian factions of the church. Constantius, who succeeded his father in 337, strongly favoured the former, or semi-Arian party, and successive synods were called with the view of adjusting differences and compelling uniformity of faith. "The highways were covered," says an ancient historian (Ammianus, xxi. 15, quoted by Gibbon, vol. iii. 67, Milman's ed.) "with troops of bishops galloping from every side to these assemblies." At length the tenet of the *Homoiousion* was substituted for that of the *Homoousion* at the Council of Rimini (Ariminum) in 360. But the war of words raged as fiercely as ever during the reigns of Julian (the Apostate) and his successors till after the accession of Theodosius the Great, under whose auspices the Council of Constantinople was convened and the Nicene doctrine was confirmed and finally accepted as the catholic doctrine of the church. Even then, however, Arianism was warmly espoused by several of the German nationalities then assailing the empire. The entire nation of the Ostrogoths became Arian; the Visigoths followed their example, till, at the request of their king, Reccared, they embraced the catholic faith at the Council of Toledo in 589. The Vandals in Africa, the Suevi in Spain, and the Burgundians in Gaul, were all for a time zealous Arians, and the heresy maintained its influence amongst the Lombards in the north of Italy to a later period than elsewhere. Gradually, however, it perished as a distinctive national type of Christianity before the growth of mediæval Catholicism, and the name of Arian ceased to represent a definite form of Christian doctrine within the church, or a definite party outside of it. Individual Christian teachers of great eminence, such as John Milton and Samuel Clark, and even Ralph Cudworth, have been accused of Arianism, but even where, as in Milton's case, the accusation seems well founded, the peculiar heresy known by that name has never assumed any influence, or regained, for any length of time, its influence in the church. (J. T.)

ARIZONA, a territory of the United States, bounded N. by Utah, E. by New Mexico, S. by Mexico, and W. by California and Nevada, with an estimated area of 113,900 square miles. According to the Act creating it a territory in 1863, Arizona comprises all the lands of the United States formerly belonging to New Mexico, extending from W. long. 109° to the California line. Since then, however, the N.W. corner has been ceded to Nevada. The territory lies in the basin of the Colorado River, which enters it in about 37° N. lat., and forms its western boundary southwards from 36°. In the north there is an extensive but barren plateau, with an average elevation of 7000 feet, through which the Colorado cuts its way, and forms one of the most remarkable gorges in the world, the length being about 300 miles, and the perpendicular walls reaching heights of from 3000 to 6000 feet. South of this plateau is the valley of the Colorado Chiquito (Little Colorado, or Flax River), which joins the Colorado in 36° 15′ lat. N. and 113° long. W., while further south the ground rises into another plateau, the main portion of which is known as the Mogollon Mountains. In this district the country is reported to be beautiful and fertile, the mountains covered with noble pine-trees, and the valleys clothed with rich grama grass. Further south, again, is the basin of the Gila, with its numerous tributaries, obliquely crossed by detached prolongations of the Sierra Madre of Mexico. The inhabitants of Arizona are mostly Indians. Of these 4300 Pinas and Maricopas occupy a reservation of 64,000 acres on the Gila River; 4000 Papagoes, a wandering tribe in the south-eastern part of the territory, have no grounds allotted them; 4000 Mohaves have 75,000 acres on the Colorado River; 2000 Yumas live near the mouth of the Colorado, but belong to the Mohave reservation; while 1500 Hualapais and 8000 or 12,000 Yavapais and Apaches, without settled habitations,

live in a state of continual warfare with their neighbours. Civilisation, however, is gradually asserting her claim to those fertile districts. Arizona is rich in mineral products—nearly all the mountains in the south and centre yielding gold, silver, copper, and lead. Lime, gypsum, and coal are also present, and salt of excellent quality exists in extensive deposits. The vegetable productions are iron-wood, mesquite, cotton-wood, sycamore, ash, oak, willow, walnut, prickly pear, cactus, aloe, artemisia; and, under cultivation, grapes, figs, oranges, lemons, tomatoes, tobacco, Indian corn, and the other cereals. Much of the land produces two crops in the year. The towns are all of inconsiderable size, and the whole white population of the territory, in 1870, did not amount to more than 9658. The capital is Tucson, in Pima county; and the other towns, Arizona City and Prescott. Many interesting remains exist of the early inhabitants of this region. See a paper by W. A. Bell, *J. of Roy. Geog. Soc.*, 1869; *Colorado Exploration;* S. W. Cozzens, *The Marvellous Country.*

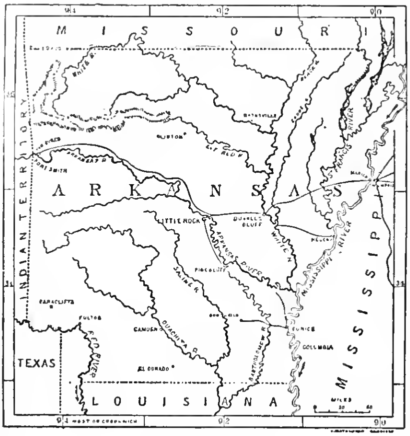
ARK OF NOAH, the vessel constructed by Noah for preservation from the approaching deluge. The Biblical account of it is contained in Genesis vi. 14–22. See NOAH.

ARK OF THE COVENANT, ARK OF THE REVELATION (E.V. ark of the testimony, Exod. xxv. 16, 22, &c.), are the full names of the sacred chest of acacia wood, overlaid with gold, which occupied the holiest place in the tabernacle and temple, and through which the idea of the constant presence of the covenant God with the people of Israel received symbolical expression. The Old Testament religion conceived of God as spiritual, and so could not think to secure His presence by the use of images. But the notion of communication between the spiritual God and His people still took the form of a *tryst* or *meeting* (מוֹעֵד E.V. wrongly, *congregation*, Exod. xxvii. 21, &c.), under conditions of time and place divinely appointed (Exod. xx. 23, 24), and the idea of purely spiritual approach to God without any local and symbolical point of *rapport* between heaven and earth was reserved for the New Testament (John iv. 21, *ff.*) In accordance with this view, certain fixed sanctuaries, consecrated by former revelations, were fit places for man to draw near to God. But the constant presence of God with the nation in its wanderings could not be realised without a portable sanctuary, the central point of which was very fitly the chest in which was contained the "revelation" (Exod. xxv. 16, xl. 20), that is, the tables of stone with the ten commandments (Exod. xxxi. 18; Deut. x. 5), which formed the basis of the covenant. This meaning of the ark is symbolically expressed by the addition of an upper piece called the *kappóreth* (E.V. mercy-seat), which was wholly of gold, and surmounted by two cherubim or symbolical winged figures, which, in the Old Testament, are always associated with the idea of local manifestations of the God who, though inaccessible to man, yet reveals himself to him. The space above the *kappóreth* and between the cherubim was conceived as the point of meeting between God and man (Exod. xxv. 22; Lev. xvi. 2); and the name *kappóreth*, which has been very variously interpreted, is probably derived from the atoning ordinances through which alone the high priest, as the people's representative, ventured to come face to face with this awful spot (Lev. xvi.)

The ark contained nothing but the tables of the law, 1 Kings viii. 9. That the pot of manna and Aaron's rod were also contained in it is an opinion resting on Heb. ix. 4, and Rabbinical tradition, but quite without evidence from the Old Testament (Exod. xvi. 33; Num. xvii. 10). That the presence of God to his people above the *kappóreth* was marked not only by artificial symbols, but by a miraculous cloud, is not certainly taught in Lev. xvi. 2, where the cloud is, according to many interpreters, the incense cloud of verse 13.

As the permanent pledge of God's gracious presence, the ark preceded the people in their march, and led them on to victory (Num. x. 33–36). During the conquest of Canaan it stood in the headquarters of the invaders, first at Gilgal, and then at Shiloh, nor does it appear to have ceased to move from place to place during the insecure period of the Judges (compare 2 Sam. vii. 6 with 1 Chron. xvii. 5), though the pre-eminence of the tribe of Ephraim seems to have kept it for the most part within their territory. At the close of this period we find it established in Shiloh. But the old tradition, that the ark is essentially the sanctuary of the armed host of Israel, with the Levites for its body guard, was not yet extinct. and it was brought into the field and captured by the Philistines in the fatal battle of Ebenezer, which broke the supremacy of Ephraim (1 Sam. iv.) Though soon restored by the Philistines who, smitten by a plague, feared to retain it, the ark could not be replaced in the central sanctuary, which had probably been destroyed in the war, and it remained in obscurity till David brought it to Zion, and again gave to the nation a religious as well as a political centre. Even in David's time the ark was carried into the field by the armies of Israel (2 Sam. xi. 11); but the king, who had himself so long maintained his religious life in banishment from the national sanctuaries, was the first clearly to express the conception, that God's help could reach forth to those who were far from Zion without any material pledge (2 Sam. xv. 25; compare Psalm iii. 4, and the idea of a heavenly temple, Psalm xviii.) So soon as this idea was reached, the importance of the ark (which ceased to be carried beyond the temple) was lost in the gradually increasing weight laid on the fixed sanctuary of Zion. Probably it was altogether lost in the counter-reformation of Manasseh, for soon after, in the beginning of the reign of Josiah, Jeremiah (iii. 16) speaks of it as missing and anxiously sought for, though 2 Chron. xxxv. 3 seems to imply that it was subsequently restored. But Jeremiah teaches that the religious significance of Jerusalem is quite independent of this symbol, and the wild legends of its preservation at the taking of Jerusalem (2 Mac. ii. and elsewhere) only show that the popular mind was unable to share the view that the ark was now an obsolete relic. More poetical is the tradition that the ark was raised to heaven, there to remain till the coming of the Messiah, which embodies the spiritual idea that a heavenly pledge of God's covenant faithfulness had superseded the earthly symbol. Compare with this Rev. xi. 19. (Ample traditional material will be found in the younger Buxtorf's dissertation *De Arca Fœderis*, Basel, 1659. For historical treatment of the subject compare especially Ewald's *Geschichte*, vol. ii., and essays by Graf in Merx's *Archiv*, i. 78, and by Kuenen in the *Theologisch Tijdschrift* for 1872, together with the usual works on Biblical Antiquities.) (W. R. S.)

ARKANSAS, one of the south-western states of the North American Union, situated between lat. 33° and 36° 30′ N., and long. 89° 45′, and 94° 40′ W., with an area of 52,198 square miles. It is bounded N. by Missouri, E. by Tennessee and Mississippi, from which it is separated by the Mississippi River, S. by Louisiana, and W. by the Indian territory. It belongs to the great basin of the Mississippi, being watered by that river and by several of its main tributaries, which are all more or less navigable. Of these the principal are the St Francis, in the north-east; the White River with its affluents, the Cache, Little Red, and Black Rivers in the north; and notably the Arkansas, which, entering the state at Fort Smith, traverses it in a south-easterly direction until it joins the Mississippi at Napoleon. The southern part of the state is watered by the Washita in the east, and by a bend of the Red River in the west. The eastern part of the state, bordering on the Mississippi, is low and swampy, and is annually overflowed. Westward the country gradually attains a greater elevation, passing off into hills and undulating prairies, which lead up to the Ozark Mountains, beyond which, again, an elevated plain stretches towards the Rocky



Sketch Map of Arkansas.

Mountains. The Ozark Mountains do not exceed 2000 feet in height, and the only other great masses of elevation are the Black Hills and the Washita Hills. A geological survey of the whole territory was commenced at the state expense by Dr David D. Owen, in 1857, and two volumes of Reports were published in 1858 and 1860. In the district north of the Arkansas River, the three leading formations are the "mill-stone grit, with its associate shales and conglomerate; the subcarboniferous limestone and its associate chert, shales, and sandstones; and the magnesian limestones, and their associate sandstones, calciferous sand-rocks and chert, belonging to the lower Silurian period." The mineral products are reported to be very considerable, "including zinc, manganese, iron, lead, and copper; marble, whet and hone stones, rock-crystal, paints, nitre-earths, kaolin, granite, freestone, limestone, marls, green-sand, marly limestones, grindstones, and slate." The zinc ores are said to compare very favourably with those of Silesia, while the argentiferous galena produces a high average percentage of silver. Of coal, anthracite, and lignite, there are abundant supplies. A great number of mineral and thermal springs occur in various parts of the state, the most remarkable and most frequented groups lying to the south of the Arkansas in Hot Springs county. The heat of several attains 146° or 148° Fahr. Among what are called natural curiosities may be mentioned the sandstone dam across Lee's Creek in Crawfurd county, the Mammoth Spring in Fulton, which is supposed to have underground connection with Howel's Valley in Missouri, and is said to pour forth its water "at the rate of 8000 (?) barrels per minute," the Bee Rock in White county, and the crystalline productions of Magnet Cove. It need hardly be said that there is great variety of soil in such a state as Arkansas. Along the river "bottoms" the alluvium is dark, rich, and deep, and yields excellent crops. The chief crops cultivated are maize, wheat, cotton, and tobacco, as well as apples and other fruits. There is a natural flora of great richness, a complete list of which is given in Dr Owen's second report. The trees and shrubs most frequently occurring are poplars, oaks, pines, sweet gum, sycamore, black locust, ash, elm, hickory, dogwood, elder, palma-christi, black spice, papaw, mocker-nut, wild vine, &c. The fauna of Arkansas includes the buffalo, eland, red-deer, beaver, otter, hare, racoon, wild turkey, goose, and quail, as well as bears and wolves among the mountains. The climate of the lower districts is decidedly unhealthy, largely on account of the lack of wholesome water; but in the upper regions it is quite salubrious. Hitherto Arkansas has been mainly agricultural, but it is rapidly advancing in the development of its mineral wealth, in the extension of its railway communication, in the embankment and guidance of its rivers, in the reclaiming of its waste but fertile lands, in the progress of manufactures and industries, and in the establishment of educational and benevolent institutions. At the census of 1870 the population amounted to 484,471, comprising 362,115 whites and 122,169 coloured persons. In 1860 the population amounted to 435,450, so that an increase of more than 10 per cent. has taken place between these two periods, principally in the white population. The capital is Little Rock, originally a French settlement, situated on the Arkansas River, and occupying a very central position in the state; population, 18,000. Arkansas was first colonised by the French, in the 17th century, and in 1720 Louis XV. made a grant of land on the Arkansas to the well-known John Law, but this led to no results of importance. In 1763 the territory was handed over to Spain, but returned to France in 1800. In 1803 it was purchased by the United States, along with the rest of what was then called Louisiana, and was established as a separate non-Indian territory in 1819. It was received into the Union as a slave state in 1836; and during the American Civil War, 1861–65, its Convention sided with the Confederate States, joining that organisation May 6, 1861.

Arkansas, a river of North America, which rises in the Rocky Mountains, in lat. 39° N., long. 106° W., 10,000 feet above the level of the sea, flows with a generally eastward direction through Colorado and part of Kansas, then turns to the south-east, and so proceeds through the rest of Kansas, the north-east part of the Indian territory, and the state to which it gives its name, and finally falls into the Mississippi at Napoleon in lat. 33° 40′ N. The length of its course is stated at 2170 miles, and its drainage-area at 178,000 square miles. It receives a large number of tributaries, of which the most important are the Cimarron, Rio Nutria, and Canadian River. It is navigable for steamboats of about 4 feet draught 40 miles above Little Rock, and during flood for some 150 miles further to Fort Gibson.

ARKLOW, a sea-port and market town in the county of Wicklow, Ireland, 50 miles from Dublin, the inhabitants of which are principally engaged in the fisheries and in copper-mines. There are oyster-beds on the coast, but the produce requires to be freed from a peculiar flavour by the purer waters of the Welsh and English coast before it is fit for food. The ruins of the ancient castle of the Ormonds, demolished in 1649 by Cromwell, still exist, but there are no traces of the monastery founded by Fitzwalter. In 1789 the Irish insurgents were defeated by the royal troops near Arklow Bridge. Population (1871), 5178.

ARKWRIGHT, Sir Richard, famous for his inventions in cotton spinning, was born at Preston in Lancashire, in 1732, of parents in humble circumstances. He was the youngest of thirteen children, received but a very indifferent education, and was bred to the trade of a barber. In the year 1760 he had established himself in Bolton-le-Moor, where he exchanged the trade of a barber for that of an itinerant hair-merchant; and having discovered a valuable chemical process for dyeing hair, he was in consequence enabled to amass a little property. It is unfortunate that very little is known of the steps by which he was led to those inventions that have immortalised his name. His residence in a district where a considerable manufacture of linen goods, and of linen and cotton mixed, was carried on, must have given him ample opportunities of becoming acquainted with the various processes that were in use in the cotton manufacture, and of the attempts that had been made and were then making to improve them. His attention was thus naturally drawn to this peculiar department; and, while he saw reason to conclude that it was likely to prove the most advantageous in which he could engage, he had sagacity and good fortune to invent and improve those extraordinary machines by which, unlike most inventors, he amassed vast wealth, at the same time that he added prodigiously to the demand for labour, and to the riches and comfort of the civilised world.

The *spinning-jenny*, invented in 1767 by Hargraves, a carpenter at Blackburn in Lancashire, gave the means of spinning twenty or thirty threads at once with no more labour than had previously been required to spin a single thread. The thread spun by the jenny could not, however, be used, except as weft, being destitute of the firmness or hardness required in the longitudinal threads or warp. But Mr Arkwright supplied this deficiency by the invention of the *spinning-frame*—which spins a vast number of threads of any degree of fineness and hardness. It is not difficult to understand the principle on which this machine is constructed, and the mode of its operation. It consists of two pairs of rollers, turned by means of machinery. The lower roller of each pair is furrowed or fluted longitudinally, and the upper one is covered with leather, to make them take a hold of the cotton. If there were only one pair of rollers, it is clear that a carding of cotton, passed between them, would be drawn forward by the revolution of the rollers; but it would merely undergo a certain degree of compression from their action. No sooner, however, has the carding, or *roving* as it is technically termed, begun to pass through the first pair of rollers, than it is received by the second pair, which are made to revolve with (as the case may be) three, four, or five times the velocity of the first pair. By this ingenious contrivance the roving is drawn out into a thread of the desired degree of tenuity, a twist being given to it by the adaptation of the spindle and fly of the common flax wheel to the machinery. Such is the principle on which Arkwright constructed his famous spinning-frame. It is obvious that it is radically different from the previous methods of spinning either by the common hand-wheel or distaff, or by the jenny, which is only a modification of the common wheel. The idea was entirely original, and was perfected and reduced to practice with consummate skill. Arkwright stated that he accidentally derived the first hint of his great invention from seeing a red-hot iron bar elongated by being made to pass between rollers; and though there is no mechanical analogy between that operation and his process of spinning, it is not difficult to imagine that, by reflecting upon it and placing the subject in different points of view, he might be led by it to his invention. The precise date of the discovery is not known; but it is most probable that the idea had occurred to his mind as early as the period when Hargraves was engaged in the invention of the jenny, or almost immediately after. Not being himself a practical mechanic, Arkwright employed John Kay, a watchmaker at Warrington, to whom we shall afterwards have to refer, to assist him in the preparation of the parts of his machine. An application in 1767 to Mr Atherton of Liverpool for pecuniary assistance was unsuccessful, though he is said to have sent some workmen to assist in the construction of the machine, the first model of which was set up in the parlour of the house belonging to the Free Grammar School at Preston.

His inventions being at length brought into a pretty advanced state, Arkwright, accompanied by Kay, and a Mr Smalley of Preston, removed to Nottingham in 1768, in order to avoid the attacks of the same lawless rabble that had driven Hargraves out of Lancashire. Here his operations were at first greatly fettered by a want of capital. But Mr Strutt of Derby, a gentleman of great mechanical skill, and largely engaged in the stocking manufacture, having seen Arkwright's inventions, and satisfied himself of their extraordinary value, immediately entered, conjointly with his partner, Mr Need, into partnership with him. The command of the necessary funds being thus obtained, Arkwright erected his first mill, which was driven by horses, at Nottingham, and took out a patent for spinning by rollers in 1769. But as horse-power was found too expensive, he built a second factory, on a much larger scale, at Cromford in Derbyshire, in 1771, the machinery of which was turned by a water-wheel, after the manner of the famous silk-mill erected by Sir Thomas Lombe. Having made several additional discoveries and improvements in the processes of carding, roving, and spinning, he took out a fresh patent for the whole in 1775; and thus completed a series of machinery so various and complicated, yet so admirably combined and well adapted to produce the intended effect in its most perfect form, as to excite the admiration of every one capable of appreciating the ingenuity displayed and the difficulties overcome.

When the vast importance of these discoveries became generally known, it is not surprising that every effort should have been made to have the patents set aside, and Arkwright deprived of the profit and honour to be derived from them. But an attentive consideration of the various proceedings relative to this subject will show that there are no good grounds for crediting the statement made in the Court of King's Bench in 1785, and again repeated by Mr Guest in his work on the cotton manufacture, which ascribes the invention of spinning by rollers to Highs, or Hayes, from whom Arkwright is said to have learned it.

Arkwright's *first* patent for spinning by rollers, which is the essential part of his inventions, was obtained, as we have previously stated, in 1769; and its value and importance were no longer doubtful after the establishment of the factory at Cromford in 1771. The success which attended this novel method of spinning naturally excited the strongest desire on the part of the Lancashire manufacturers to participate in the advantages to be derived from it; and the fair presumption is that, instead of attempting clandestinely to pirate the invention, they would, had they conceived there were any good grounds to go upon, have at once contested the validity of the patent. But no such attempt was made till 1781, *twelve* years after the date of the first patent, and *six* years after the date of the second. And even then, Arkwright's opponents came forward only in consequence of his having resolved to vindicate his rights, which had begun to be invaded on all sides, by raising an action against Colonel Mordaunt for an infringement of his patent. Mordaunt was supported by a combination of manufacturers; and, as they felt the question to be of the greatest importance, it is all but impossible to suppose that anything would be omitted on their part which was conceived likely to contribute to their success. The case having been tried in the Court of King's Bench, after Trinity term, July 1781, the decision was unfavourable to Arkwright. But it is of importance to observe, that no attempt was made at the trial to charge him with having purloined the inventions of others, and that the verdict was given on the sole ground of the *description of the machinery in the specification being obscure and indistinct.* Arkwright admitted that this was partly the case; adding, however, that the obscurity had been intended only to prevent foreigners from pirating his inventions. On any other principle, indeed, his conduct would be inexplicable; for, as his inventions were fully known to hundreds of workmen in his own employment, and as he had sold the privilege of using them to many persons in different parts of the country, it is impossible to suppose that he could either have expected or intended to conceal his inventions after the expiration of his patent. In consequence of the result of this trial, Arkwright and his partners prepared a "case," setting forth the value of the inventions, and the circumstances which had led to the indistinctness complained of in the specification, which they at one time intended to lay before Parliament, as the foundation of an application for an Act for their relief. But this intention was subsequently abandoned; and in a new trial (Arkwright *v.* Nightingale), which took place in the Court of Common Pleas on the 17th of February 1785, Lord Loughborough, the presiding judge, having expressed himself favourably with respect to the sufficiency of the specification, a verdict was given for Arkwright. On this, as on the former trial, nothing was stated against the originality of the invention.

In consequence of these conflicting verdicts, the whole matter was brought, by a writ of *scire facias*, before the Court of King's Bench, to have the validity of the patent finally settled. And it was not till this third trial, which took place before Mr Justice Buller and a special jury, on the 25th of June 1785, that Arkwright's claim to the inventions which formed the subject of the patent was disputed. To support this new allegation, Arkwright's opponents brought forward, for the first time, Highs, or Hayes, a reed-maker at Bolton. He stated that he had invented a machine for spinning by rollers previously to 1768; that he had employed the watchmaker Kay to make a model of that machine; and Kay was produced to prove that he had communicated that model to Arkwright, and that that was the real source of all his pretended inventions. Having no idea that any attempt was to be made at so late a period to overturn the patent on this new ground, Arkwright's counsel were not prepared with evidence to repel this statement; but it was stated by Mr Sergeant Adair, on a motion for a new trial on the 10th of November of the same year, that he was furnished with affidavits contradicting, in the most pointed manner, the evidence that had been given by Kay and others with respect to the originality of the invention. The court, however, refused to grant a new trial, on the ground that, whatever might be the fact as to the question of originality, the deficiency in the specification was enough to sustain the verdict. But, independently altogether of the statements made on the motion for a new trial, the improbability of the story told by Highs and Kay seems glaring and obvious. Highs states in his evidence that he had accused Arkwright of getting possession of his invention by means of Kay so early as 1769, or about that period. Where, then, it may be asked, was this Mr Highs ever since that period, and particularly during the first trial in July 1781, and the second in February 1785? Living in Lancashire, associating with manufacturers, and in the habit, as he declares in his evidence, of making machines for them, he could not fail to be speedily informed with respect to the vast importance and value of the invention Arkwright had purloined from him. It is impossible but he must have been acquainted with the efforts that were making by the Lancashire manufacturers to set aside the patents; and is it to be supposed, had he really been the inventor, that he would have remained for *sixteen* years a passive spectator of what was going forward? that he would have allowed Arkwright to accumulate a princely fortune by means of *his* inventions while he remained in a state of poverty? or that he would have withheld his evidence when the manufacturers attempted to wrest from Arkwright what he had so unjustly appropriated? A single hint from Highs or Kay would, had their story been well founded, have sufficed to force Arkwright to give them a share of his profits, or would have furnished the manufacturers with the means they were so anxious to obtain, of procuring the immediate dissolution of the patents. But it has never been alleged that Arkwright took any pains to conciliate these persons; on the contrary, he treated Highs with the most perfect indifference, and not only dismissed Kay from his service, but even threatened to prosecute him on a charge of felony. The supposition that persons with so many and such overpowering temptations to speak out, and with no inducement of any sort to be silent, should have kept so important a secret for so many years is almost incredible; and it is infinitely more consistent with probability to suppose that the story of Highs and Kay had been manufactured for the occasion than that it was really true. None of Arkwright's most intimate friends ever had the slightest doubt with respect to the originality of his invention. Some of them, indeed, could speak to the circumstances from their own personal knowledge; and their testimony was uniform and consistent.

On their introduction, Arkwright's machines were regarded by the lower classes as ever more adverse to their interests than those of Hargraves, and repeated attacks were made on the factories built for them. But however extraordinary it may appear, it was amongst the manufacturers that the greatest animosity existed against Arkwright; and it required all the prudence for which he was so remarkable to enable him to triumph over the powerful combination that was formed against him. At the outset of the business they unanimously refused to purchase his yarn; and when his partners, Messrs Strutt and Need, had commenced a manufacture of calicoes, the manufacturers strenuously opposed a bill to exempt calicoes from a discriminating duty of 3d. a yard laid on them over and above the ordinary duty of 3d. by an old Act of Parliament. Luckily, however, the manufacturers failed of their object; and, in 1774, an Act of Parliament was obtained (14 Geo. III. cap. 72) for the encouragement of the cotton manufacture, in which fabrics made of cotton are declared to have been *lately* introduced, and are allowed to be used as "a lawful and laudable manufacture;" the duty of 6d. the square yard on such cottons as are printed or stained being at the same time reduced to 3d. But this disgraceful spirit of animosity, which must, had it been successful, have proved as injurious to the interests of the manufacturers as to those of Arkwright, did not content itself with actions in the courts of law, or a factious opposition to useful measures in Parliament, but displayed itself in a still more striking and unjustifiable manner. A large factory, erected by Arkwright at Birkacre, near Chorley, in Lancashire, was destroyed by a mob collected from the adjacent country, in the presence of a powerful body of police and military, without any one of the civil authorities requiring them to interfere to prevent so scandalous an outrage.

Fortunately, however, not for himself only, but for his country and the world, every corner of which has been benefited by his inventions, Arkwright triumphed over every opposition. The same ingenuity, skill, and good sense, which had originally enabled him to invent his machine and get it introduced, enabled him to overcome the various combinations and difficulties with which he had subsequently to contend.

Though a man of great personal strength, which he is said to have displayed, when young, in election riots at Preston, Arkwright never enjoyed good health. During the whole of his memorable career of invention and discovery, he was labouring under a very severe asthmatic affection. A complication of disorders at length terminated his truly useful life in 1792, at his works at Cromford, in the sixtieth year of his age. He was high sheriff of Derbyshire in 1786; and, having presented a congratulatory address from the wapentake of Wirksworth to his Majesty George III., on his escape from the attempt on his life by Margaret Nicholson, received the honour of knighthood. No man ever better deserved his good fortune, or has a stronger claim on the respect and gratitude of posterity. His inventions have opened a new and boundless field of employment; and while they have conferred infinitely more real benefit on his native country than she could have derived from the absolute dominion of Mexico and Peru, they have been *universally* productive of wealth and enjoyment.

ARLES (*Arelate*), a city of France, in the department of Bouches du Rhône, 46 miles north-west of Marseilles, in lat. 43° 40′ 18″ N., long. 4° 37′ 46″ E. It stands on the left bank of the Rhone, where that river divides to form its delta. It is generally well built, with regular streets and fine quays. The public buildings consist of the town-hall, dating from Louis XIV., and built after plans by Mansart; the cathedral of St Trophime, founded in the 7th century and remarkable for its portico; a college, museum, school of navigation, and public library. The building of railway waggons, &c., is largely carried on, as well as the manufacture of silk, glass-bottles, and soap, and the sausages of Arles are famed for their excellence. The trade in agricultural produce, oil, wine, fruits, cattle, wool, and salt, is considerable. A canal (called after the city) has been constructed from Arles to the harbour of Bouc on the Mediterranean, and a connection is formed with the canals of Beaucaire and Craponne. The latter affords communication with the Durance. Population in 1872, 24,695.

Arelate was an important town at the time of Cæsar's invasion, and subsequently received a Roman colony, and became under the later emperors one of the most flourishing towns on the further side of the Alps. It was pillaged in 270 A.D., but restored and embellished by Constantine, who made it his principal residence, and founded what is now the suburb of Trinquetaille. After the fall of the Roman empire the city passed into the power of the Visigoths, and rapidly declined. It was plundered in 730 by the Saracens, but in the 10th century became the capital of a kingdom of the same name, formed by Bozon from the two kingdoms of Burgundy. In the 12th century it was a free city, governed by *consuls* and *podestats* after the model of the Italian republics, which it also emulated in commerce and navigation. In 1251 it submitted to Charles of Anjou, and from that time onwards followed the fortunes of Provence. A number of ecclesiastical councils have been held here, as in 314,—when the Donatists were condemned,—354, 452, and 475. Arles still possesses many monuments of Roman architecture and art, the most remarkable being the ruins of an amphitheatre (*arènes*), capable of containing 20,000 spectators, which was turned, by Abd-el-Rahman, into a fortress and flanked with four massive towers, of which two are still standing. There are also a theatre, in which, besides the famous Venus of Arles, discovered in 1651, many other remains have been found; an ancient obelisk of a single block, 47 feet high, erected in 1676 in the *Place Royale*; and the ruins of two temples, an aqueduct, and a triumphal arch. There is, besides, a Roman cemetery of great beauty, which has been laid out as a public pleasure-ground, and bears the name of Aylscamps or Eliscamps, which hardly conceals the original designation, "*Elysii Campi*." (See Clair, *Monuments d'Arles*, 1837; Millin, *Voy. dans les départ. du Midi de la France*; Estrangin, *Etudes archéol. sur Arles*.)

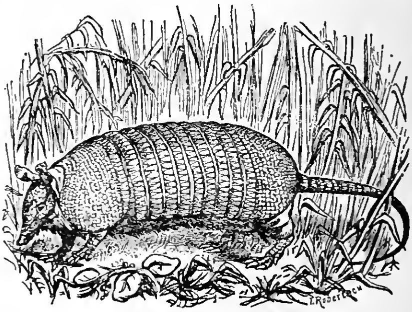
ARLON (*Orolaunum* in the Antonine Itinerary), the capital of the Belgian province of Luxemburg, is situated on a rising ground in the midst of a well-cultivated plain. It is a flourishing place of some 5000 or 6000 inhabitants, who are engaged in the manufacture of iron-wares, tobacco, crockery, and clay-pipes, and carry on a trade in grain. Antiquities found on the spot seem to indicate a Roman settlement. Under its present name the town is mentioned in 870. At one time an independent marquisate, it was united to the countship of Luxemburg in 1214. In the neighbourhood was the nunnery of Clairefontaine or Bardenburg, established about 1216, which is now a foundry.

ARMADA, a Spanish word, meaning generally an armed force or fleet, is applied specially to designate the great expedition sent out against England in 1588 by Philip of Spain. His principal motive for this enterprise was the desire to strike a decisive blow at the Protestant faith, of which England was then the bulwark. For many months the whole energies of the Spanish nation had been directed towards the construction and equipment of the requisite ships. In 1587 everything was nearly ready, but the sailing of the expedition was delayed for a year by Drake, who made a bold dash into the harbour of Cadiz and destroyed nearly a hundred ships, with immense stores of provisions. A further delay was caused by the sudden death of the marquis of Santa Cruz, who had been originally intrusted with the chief command. His loss was a serious blow to the Spanish cause, for he was an experienced sailor. The duke of Medina Sidonia, a man almost entirely ignorant of naval affairs, was then made admiral. All preparations being at length completed, the great fleet sailed from Lisbon on the 29th (19th o. s.) May 1588. It consisted of 129 large vessels, and carried 19,295 soldiers, 8460 sailors, besides slaves as rowers, and 2431 cannon. Their destination was the coast of Flanders, where Alexander Farnese, prince of Parma, was lying with about 35,000 men and a flotilla of boats. This force was to be landed on the Isle of Thanet at the mouth of the Thames, under the protection of the Armada, which would be able to keep the Channel perfectly clear. Another body of troops was then to be landed further north; and it had been hoped at one time that the duke of Guise would effect a diversion by landing a force on the west coast. These plans, however, were considerably deranged by the length of time occupied in preparing the expedition, and by the further delays encountered. For the fleet had scarcely sailed from Lisbon, when it was overtaken by a severe storm, which shattered several of the ships, and compelled them all to put in for repairs at Coruña. It was the 22d (12th) July before they finally sailed from Spain. England meanwhile had not been idle; when the news arrived that the great expedition was really about to set out, the most intense enthusiasm took possession of the people, who gladly furnished ships and stores, and raised volunteer bands for coast defence. The command of the army was given to the earl of Leicester, who took his post, with about 16,000 men, at Tilbury to oppose the landing of Parma. About 45,000 were assembled round the Queen, to protect her person. The royal navy, which consisted of about thirty ships, was at once put in order, and gradually increased, by the addition of merchantmen and privateers, to about 180 vessels. These carried about

18,000 sailors, but they had not half the weight of the Spanish artillery, and they were scantily supplied with ammunition and provisions. The ships, however,—those of the Queen in particular,—were in splendid order, and the sailors were the finest in England. The lord high admiral was Lord Howard of Effingham, who had under him Drake, Hawkins, Frobisher, and others, the most celebrated mariners of the age. He took his station with the main body of the ships, about eighty in number, at Plymouth, and another squadron, under Lord Seymour, cruised off Dunkirk, commanding the straits and blockading the prince of Parma. Meantime news was brought to England that the Armada had encountered severe storms, and that the expedition was given up. So much faith was put in this report that several ships began to discharge their crews. Howard, however, sailed down towards Coruña, and discovered that the report had no foundation. On the 29th (19th) July, the fleet was observed entering the Channel, and the beacon-lights along the coast gave warning to England that the dreaded enemy was at hand. That evening Howard's ships were moored so as to be able to slip out of Plymouth Sound at a moment's notice. On the following day the Armada was seen standing up the Channel in the form of a crescent, seven miles long, and numbering 150 ships. They passed Plymouth towards evening, and during the night the English fleet sailed out of the Sound, and took up a position to windward. On the following day the action began by the duke of Medina Sidonia attempting to close and come to a general engagement. But he found this to be impossible; the English ships, light and admirably handled, sailed so swiftly, and were manœuvred with such dexterity, that it was out of his power to inflict any injury on them. Their fire also was rapid and deadly, while the Spanish guns were worked slowly, and generally sent the shot far over the light English vessels. Dismayed at their want of success, the Spanish fleet stood off up the Channel, closely pursued by the English. Throughout all the next week the same tactics were pursued; the English, hovering on the rear of the Armada, harassed and weakened it without coming to a general engagement. At length, on the 6th August (27th July), Medina Sidonia cast anchor in the roads of Calais, and sent messengers to the prince of Parma, asking him for ammunition and light vessels, and suggesting that he should now attempt his landing on the coast of England. But the prince declared that it was impossible to cross the Channel while the English fleet was on the sea, that he had no light ships, and that the state of the weather prevented him sending such ammunition as he could spare. Lord Howard had now been joined by Seymour's squadron and by many private ships, but he and the other commanders were still in the deepest anxiety. They were almost destitute of provisions and powder, and did not yet know what damage they had inflicted on the Armada, which, after all their endeavours, seemed now to have reached its destination. At last it was resolved to drive the Spanish fleet out into the open sea, and to effect this by means of fire-ships. Eight ships were selected and filled with combustibles, their rigging was smeared with pitch, and on the night of the 7th August (28th July) they were drifted down with the tide and set on fire. The Spaniards, in great alarm, immediately cut their cables and cleared off from the shore. Next morning Drake pursued them, while Howard remained for some time to attack a galleon that had gone ashore during the night. The Spanish fleet was scattered over a large space off Gravelines, and Drake at once began the action, driving them together into a confused mass by his rapid firing and swift manœuvring, and forcing the whole towards the coast of Flanders. Had his ammunition held out he might have completed the ruin by driving them on shore; as it was, the injury inflicted by this one day's fighting was enormous. Nearly 4000 men were killed and many ships were disabled, and the hopes of the Spaniards were broken. Their courage completely deserted them; and next day, when a council of war was held, it was resolved to try the perilous voyage to Spain by the North Sea and Pentland Firth rather than again face Drake and the English fleet. The whole fleet, still numbering 120 vessels, stood off accordingly towards the North Sea. Drake and Howard pursued for some days, till want of provisions compelled them to return. But the weather proved a sufficiently formidable enemy to the unhappy Spaniards. The continuous violent gales which accompanied them along their route, by the north of Scotland and the wild Irish coast, completely shattered their unseaworthy vessels. The shores were strewn with wrecks, and many hundreds of unfortunates who were saved from the sea were slain by the Irish. Constant sickness had decimated the troops, and when at length, in September and October, fifty-four shattered vessels reached Spain, they conveyed only 9000 or 10,000 men, and these were in a pitiable state from sickness and want.

A full account of the Armada is given in the curious Spanish work, *La felicisima Armada, &c.*, published in 1588, a copy of which, with Lord Burleigh's manuscript notes, is in the British Museum. Froude (*History*, vol. xii.) gives valuable extracts from Spanish manuscripts bearing on the expedition.

ARMADILLO, a family of South American mammals (*Dasypidæ*), belonging to the order Edentata, and distinguished by the peculiar nature of their external covering. This consists of a bony case, partly composed of solid buckler-like plates, and partly of movable transverse bands, the latter differing in number with the species, and, to a certain extent, with the age and sex of the individual, and giving to the entire body a considerable degree of flexibility. The under parts are destitute of bony covering, but in every case are more or less thickly covered with hair. The legs of the armadillo are short, and its movements usually slow, although, when pursued, it is said to be able to outrun a man. In danger, however, it chiefly depends for safety on its long, powerful claws, by which it can bury itself, in a few minutes, several feet below the surface of the ground. Most of the species are nocturnal in their habits, with small, weak eyes, but highly developed organs of hearing and smelling. They all possess molar teeth, and, with the exception of a single species, those only. Their food consists principally of fruits, roots, worms, and insects, but a few species are more carnivorous, greedily devouring the semi-putrid carcases of the wild



The Peba (*Tatusia Peba*, Owen).

cattle of the *pampas*, and even, it is said, burrowing into human graves. All the species are eaten by the natives and by the Portuguese and Spanish settlers, who esteem them a delicacy when roasted in the shell. The habitat of the armadilloes, extending from Mexico and Texas southward to Patagonia, is the region which, during the Tertiary period, was inhabited by the Glyptodons—gigantic armadilloes as large as the rhinoceros, whose remains are found abundantly in the bone-caves of Brazil.

ARMAGH, an inland county of Ireland in the province of Ulster, situated between lat. 54° 3′ and 54° 31′ N., and long. 6° 14′ and 6° 45′ W.; comprising an area of 328,086 statute acres, of which 178,064 are under tillage, 100,137 in pasture, 4670 in plantation, and 28,177 in waste, &c., while 17,038 acres are under water. It is bounded on the N. by Lough Neagh, on the E. by the county of Down, on the S. by Louth, and on the W. by Monaghan and Tyrone. The general surface of the county is gently undulating and pleasingly diversified; but in the northern extremity, on the borders of Lough Neagh, is a considerable tract of low, marshy land, and the southern border of the county is occupied by a barren range of hills, the highest of which, named Slieve Gullion, attains an elevation of 1893 feet, being the highest mountain in Ulster excepting Slieve Donard in the county of Down. The summit of Slieve Gullion, commanding one of the finest prospects in the province, is crowned by a large cairn or pile of stones, which forms the roof of a singular cavern of artificial construction. In the western portion of the county are the Few Mountains, a chain of abrupt hills mostly incapable of cultivation.

The soil of the northern portion of the county is a rich, brown loam, on a substratum of clay or gravel, with an abundance of limestone near Armagh and other places. Towards Charlemont there is much reclaimable bog resting on a limestone substratum. The eastern portion of the county is generally of a light friable soil; the southern portion rocky and barren, with but little bog except in the neighbourhood of Newton Hamilton. The climate of Armagh is considered to be one of the most genial in Ireland, and less rain is supposed to fall in this than in any other county.

The county is well watered by numerous streams. The principal are the Callen, the Tynan, and the Tallwater, flowing into the Blackwater, which, after forming the boundary between this county and Tyrone, empties itself into the south-western angle of Lough Neagh. The Tara, the Newtown-Hamilton, the Creggan, and the Fleury flow into the Bay of Dundalk. The Cam or Camlin joins the Bann, which, crossing the north-western corner of the county, falls into Lough Neagh to the east of the Blackwater. The Newry canal, communicating with Carlingford Lough at Warrenspoint, six miles below Newry, proceeds northwards through the county of Armagh for about 21 miles, joining the Bann at Whitecoat. The Ulster Canal commences at Charlemont on the River Blackwater, near its junction with Lough Neagh, proceeding through the western border of the county, and passing thence to the south-west by Monaghan and Clones into Upper Lough Erne, after a couse of 48 miles.

The geological features of the county are various and interesting. The granite of Slieve Gullion, an offset of the granite district of Down, is often used for millstones, being very hard and fine grained. The Newry Mountains and the Fathom Hills are also composed of granite. Around Camlough large beds of mica-slate exist. Slate quarries have been worked partially at Dorcy, Newtown-Hamilton, Creggan Duff, and in the neighbourhood of Crossmaglen. Lead mines have been worked, but without much success, in several parts of the county. There are extensive deposits of lignite in the district near Lough Neagh. The other mineral substances found are potters' clay and a variety of ochres.

The total population in 1821 amounted to 197,427 souls. In 1831 the population was 220,134, and in 1841 it was 232,393, but in 1851 the numbers had declined to 196,085, and by the census of 1871 it was 179,260.

The land is in general but indifferently cultivated, yet owing to the occupation of the peasantry in the linen manufacture they are better lodged, clothed, and fed than in most other parts of Ireland. The cultivation of grain has been for some time slightly on the decrease, and the number of acres under flax diminished from 27,245 in 1866 to 7530 in 1872; but in the green crops there has been considerable increase. The total number of acres under crops amounted in 1872 to 172,550, viz., wheat, 10,599; oats, 68,487; barley, bere, and rye, 379; beans and pease, 254; potatoes, 32,799; turnips, 7998; other green crops, 3287; flax, 7530; meadow and clover, 41,164.

The farms are in general very small, and show less tendency to decrease in number than in most other parts of Ireland. In 1872 there were 6220 holdings of less than five acres each. Notwithstanding this, their owners are generally in circumstances of comparative comfort, owing to their employment in the linen manufacture. There are few who do not keep at least one cow, or a few sheep; none but the poorest cottar is without a pig. The usual diet is oatmeal, potatoes, and milk-porridge, varied sometimes by salt-herrings. The better description of farmers use animal food, chiefly bacon and poultry.

The principal manufacture, and that which has given a peculiar tone to the character of the population, is still that of linen, though it has somewhat declined of late. It is noways necessary to the promotion of this manufacture that the spinners and weavers should be congregated in large towns, or united in crowded and unwholesome factories. On the contrary, most of its branches can be carried on in the cottages of the peasantry. The men devote to the loom those hours which are not required for the cultivation of their little farms; the women spin and reel the yarn during the intervals of their other domestic occupations. Smooth lawns, perennial streams, pure springs, and the open face of heaven, are necessary for perfecting the bleaching process. Hence the extensive bleachers dwell in the country with all their assistants and machinery. Such is the effect of this combination of agricultural occupations with domestic manufactures, that the farmers are more than competent to supply the resident population of the county with vegetable, though not with animal food; and some of the less crowded and less productive parts of Ulster receive from it a considerable supply of oats, barley, and flour. Apples are grown in such quantities as to entitle the county to the epithet applied to it, the orchard of Ireland.

The antiquities consist of cairns and tumuli; the remains of the fortress of Eamania near Armagh, once the residence of the kings of Ulster; the Dane's Cast, an extensive fortification in the south-east of the county, extending into the county of Down; spears, battle-axes, collars, rings, amulets, medals of gold, ornaments of silver, jet, and amber, &c., have also been found in various places. The religious houses were at Armagh, Clonfeacle, Killevy, Kilmore, Stradhailloyse, and Tahenny. Of military antiquities the most remarkable are Tyrone's ditches, near Poyntz-Pass, Castle Roe, the fort of Navan, the castles of Criff-Keirn and Argonell, and that in the pass of Moyrath.

Armagh, together with Louth, Monaghan, and some smaller districts, formed part of a territory called Orgial or Urial, which was long subject to the occasional incursions of the Danes.

The county was made shire ground in 1586, and called Armagh after the city, by Sir John Perrott. When James I. proceeded to plant with English and Scotch colonists the vast tracts escheated to the crown in Ulster, the whole of the arable and pasture land in Armagh, estimated at 77,800 acres, was to have been allotted in sixty-one portions. Nineteen of these, comprising 22,180 acres, were to have been allotted to the church, and forty-two, amounting to 55,620 acres, to English and Scotch colonists, servitors, native Irish, and four corporate towns,—the swordsmen to be dispersed throughout Connaught and Munster. This project was not strictly adhered to in the county of Armagh, nor were the Irish swordsmen or soldiers transplanted into Connaught and Munster from this and some other counties.

Armagh is now divided into eight baronies, viz., Armagh, Fews Lower and Upper, Oneiland East and West, Orior Lower and Upper, and Tiranny. It contains twenty-nine parishes and parts of parishes, the greater number of which are in the archdiocese of Armagh, and a few in the diocese of Dromore. The county is in the Belfast military district, having barracks at Armagh and Newry. The constabulary force has its headquarters at Armagh, the county being divided into five districts. Assizes are held at Armagh, where the county prison, the county infirmary, and the district lunatic asylum are situated. The only savings bank in the county is at Armagh. There are two poor-law unions, Armagh (partly in Tyrone) and Lurgan (partly in Antrim and Down). The valuation of rateable property in 1872 amounted to £410,757. The chief towns are—Armagh, population in 1871, 8946; Lurgan, 10,632; Portadown, 6735; and part of Newry, with 5321 inhabitants, the remainder of this place, with 9616 inhabitants, being in the county of Down. The county returns three members to the imperial parliament, two for the county generally,—constituency in 1873, 7044; and one for Armagh city,—constituency, 621.

In the towns and level parts of the county the Protestant religion, in its two principal forms of the Episcopal and Presbyterian, predominates; but the Roman Catholic faith is prevalent in the mountainous and less cultivated parts. By the census returns of 1871 the Roman Catholics number 85,057, or nearly one-half of the gross population. The number of children at school in 1871 amounted to 19,887, of whom 14,838 attended the various "National Schools." There were in the same year twenty-one persons who knew nothing but the native Erse, and 3903 were able to speak both that language and the English.

ARMAGH, a city and parliamentary borough in the above county, 64 miles north of Dublin, in lat. 54° 20′ 55″ N., and long. 6° 37′ 57″ W. It derives its name of *Ard-macha*, or High Field, from its situation on the sides of a steep hill called Drumsailech, or the Hill of Willows, which rises in the midst of a fertile plain. Of high antiquity, and, like so many other Irish towns, claiming to have been founded by St Patrick, it long possessed the more important distinction of being the metropolis of Ireland; and, as the seat of a flourishing college, was greatly frequented by students from other lands, among whom the English and Scotch were said to have been so numerous as to give the name of Trian-Sassanagh, or Saxon Street, to one of the quarters of the city. Of a synod that was held here as early as 448, we have interesting memorials in the *Book of Armagh*. Exposed to the successive calamities of the Danish incursions, the English conquest, and the English wars, and at last deserted by its bishops, who retired to Drogheda, the venerable city sank into an insignificant collection of cabins, with a dilapidated cathedral covered with shingles. From this state of decay, however, it was raised by the unwearied exertions of Primate Robinson (otherwise Lord Rokeby), which, seconded as they have been by similar devotion on the part of his successors of the Beresford family, have made of Armagh one of the best-built and most respectable towns in the country. As the ecclesiastical metropolis of both the Anglican and Roman organisations, it possesses two cathedrals—of which the Catholic is of the more recent construction—and two archiepiscopal palaces. As the county town it has a court-house, a prison, a lunatic asylum, and a county infirmary. Besides these, there is a fever hospital, erected by John George Beresford; a college, which Primate Robinson was very anxious to raise to the rank of a university; a public library founded by him, and containing upwards of 14,000 volumes; an observatory, which has become famous from the efficiency of its astronomers; and a number of churches and schools. Almost all the buildings are built of the limestone of the district, but the Anglican cathedral is of red sandstone. Population of the parliamentary borough in 1871, 8946.

ARMAGNAC, a district of the south of France, corresponding to a large part of the present department of Gers, with portions of the neighbouring territory, erected in the 10th century into a countship in favour of Bernard the Squint-eyed (le Louche), son of the count of Fezinsac. The family thus founded at various times exercised great influence on the destinies of France, especially in the persons of John I. (d. 1373), Bernard VII. (d. 1418), John IV. (d. 1451), and John V. (d. 1473). Under Bernard VII. the name Armagnacs was given to the party of the house of Orleans, which carried on so ruthless a contest with the house of Burgundy during the imbecile reign of Charles VI. In 1444–5, the Emperor Frederick III. of Germany obtained from Charles VII. a large army of Armagnacs to enforce his claims in Switzerland, and the war which ensued took the name of the Armagnac war (*Armagnakenkrieg*). In Germany the name of the foreigners, who were completely defeated in the battle of St Jakob on the Birs, not far from Bâle, was mockingly corrupted into *Arme Jacken*, Poor Jackets, or *Arme Gecken*, Poor Fools. On the death of Charles of Armagnac, in 1497, the countship was united to the crown by Charles VII., but was again bestowed on Charles, the nephew of that count, by Francis I., who at the same time gave him his sister Margaret in marriage. After the death of her husband, by whom she had no children, she married Henry of Albret, king of Navarre; and thus the countship of Armagnac came back to the French crown along with the other dominions of Henry IV. In 1645, Louis XIV. erected a countship of Armagnac in favour of Henry of Lorraine, count of Harcourt, in whose family it continued till the Revolution. James of Armagnac, grandson of Bernard VII., was made duke of Nemours in 1462, and was succeeded in the dukedom by his second son, John, who died without issue, and his third son, Louis, in whom the house of Armagnac became extinct in 1503.

ARMENIA (*Hayasdani* or *Haikh*, in the native language), formerly an extensive country of Western Asia, which is now divided between Turkey, Russia, and Persia. Its political relations, and consequently its geographical limits, were subject to frequent variation, but in its widest extent it may be described as reaching from the Caucasus in the N. to the Mountains of Kurdistan in the S., and from the Caspian Sea in the E. to Asia Minor in the W., frequently, indeed, somewhat overlapping with the last-mentioned geographical division. From a very early period a distinction was drawn between Greater Armenia (*Armenia Major, Medz Hayotz*), to the east of the Euphrates, and Lesser Armenia (*Armenia Minor, Phokhr Hayotz*), lying to the west. The former is more properly Armenia. It consists for the most part of an elevated table-land, about 7000 feet above the level of the sea, culminating in the peaks of Mount Ararat, and sinking towards the plains of Iran on the east and those of Asia Minor in the west, while it is frequently broken by glens and valleys. It is watered by the Euphrates, the Tigris, the Aras, and the Kur, all of which have their sources within its borders; and, like other mountainous countries, it possesses a large number of lakes. The most important of these are Van or Aghtamar, Sevan or Khabodan, and Urmiah or Keghem. The country is naturally fertile, producing grain, cotton, tobacco, and grapes, but for many centuries it has been sadly neglected. It abounds in romantic scenery and luxuriant pasture. The beauty of the district of Ararat especially has been celebrated by patriotic historians like Moses of Khorene and Lazarus of Pharb. In the time of its greatest prosperity, Armenia Major was divided into fifteen provinces, and contained a large number of flourishing and important towns. The capital for many centuries, under the Haikian dynasty, was Armavir, to the north of the Araxes, but it was changed for Artaxata (Ardashad) towards the close of the first century of our era. Erovant II. (58–78 A.D.) built Erovantashad and Pakaran, and adorned them with the spoils of the earlier cities. From the 2d to the 4th century the royal residence was at Valarsabad, which no longer exists, and, under the Pagratid dynasty, the chief town was first Shiragavan and afterwards Ani, the remains of which still testify to its magnificence. (Texier, *Description de l' Arménie;* Brosset, *Ruines d'Ani,* 1860, 1861.) Other places of importance were Erzeroum, Van or Shamiramaguerd, Nakhjuan, Amid, and Pakovan. Divided and incorporated by the three great empires already mentioned, Armenia has no longer a separate existence, and details regarding the present condition of the country that formerly bore the name come more appropriately elsewhere. The Russian portion extends south to the Aras, and is mainly included in the government of Erivan; the Persian share is absorbed in Azerbijan; and Turkish Armenia is principally contained in the province of Erzeroum. The chief towns in the first are Erivan, Etchmiadzin, Ordubad, and Alexandropol; in the second, Urumiyah; and in the third, Erzeroum and Van.

According to their own legendary history, in which ancient traditions are curiously incorporated with Biblical lore, the Armenians are descendants of Haik, a son of Togarmah, the grandson of Japhet, who fled from the tyranny of Belus of Assyria and settled in the country which now, in their language, bears his name. The conquest of the land by Semiramis, and the revolt of Barvir against Sardanapalus, are the chief events in the early ages. Tigranes or Dikran is regarded as the contemporary and ally of Cyrus, and the history of his reign is recorded in detail. His son, Vahakin, who succeeded him, was celebrated for his strength, and was deified after his death. The dynasty came to an end in the person of Vahi, who was defeated by Alexander the Great, 328 B.C.

The Armenians threw off the Macedonian yoke in 317 B.C., and chose Ardvates as their king; but on his death, about thirty-three years afterwards, they submitted to the Seleucids of Syria. About 190 B.C., Artaxias, who had been appointed governor by Antiochus the Great, took advantage of that monarch's defeat by the Romans and proclaimed Armenia Major independent. It was this prince who afforded an asylum in his court to the exiled Hannibal. The example of revolt was followed in Lesser Armenia by Zadriades, whose descendants maintained their position till the time of Tigranes II., when their territory was annexed to Greater Armenia.

About the middle of the 2d century B.C., the great Parthian king, Mithridates I., who had already extended his empire over Syria, established his brother, Valarsaces (Wagharshag), in Armenia, and thus rendered him the founder of one of the most important branches of the Arsacid family. The new king greatly promoted the prosperity of the country by founding cities, establishing laws, and rewarding persons of talent. The most celebrated of his successors was his great-grandson, Tigranes II., who made himself master of Syria, the Lesser Armenia, and many Parthian provinces, and would, probably, have been the founder of an extensive empire had not the solicitations of his father-in-law, Mithridates of Pontus, brought him into collision with the Romans. In reward for the submission which he ultimately made to Pompey, he was allowed to keep possession of Armenia, with the exception of the provinces of Sophene and Gordyene, which were erected into a separate kingdom for his son, Tigranes. He continued a faithful ally of the Romans till his death, about 55 B.C., when he was succeeded by his son, Artavasdes, who, having adopted a more independent policy, was taken prisoner by Antony and carried to Alexandria, where he was afterwards beheaded by Cleopatra in 30 B.C.

Arsacid dynasty, 149 B.C.–428 A.D.

Roman influence and supremacy

A period follows of nominal Roman supremacy and actual anarchy; 170 independent families all asserting themselves to the best of their ability, and a few of them succeeding in establishing their petty principalities. At length a usurper, Erovant, an Arsacid by the female line made himself in some sort master of all the kingdom about 58 A.D., and maintained his position till he was expelled by Ardashes (Exedarus), a more direct representative of the race, who was repeatedly dethroned and restored by Parthian and Roman interference, but managed to do something for the amelioration of his country.

Subjection to Persia, 232 A.D.

When the Arsacids were driven from the Persian throne by the Sassanid Artaxerxes (Ardeshir), Chosroes the Great of Armenia naturally took up arms in their defence; and he maintained the contest till his assassination by Anag, an Arsacid prince of Persia, when Armenia became subject to the Persian dynasty, 232 A.D. In the massacre of the royal family which ensued, none escaped but Tiridates (Tirdat), a son of Chosroes, who fled to Rome, and afterwards, with the help of the Romans, established himself on the throne, 259 A.D. The first act of his reign was the persecution of the Christians, who had begun to take root in the country during the previous century. St Gregory, surnamed the Illuminator, was cast into prison; but the king being, as he supposed, miraculously cured of a dangerous distemper by the saint, the Christian religion was embraced by himself and most of his people. The introduction of Christianity tended to arouse the animosity of the Persians; and from this period Armenia became the theatre of almost uninterrupted struggles between that nation and the Romans, until Theodosius the Great agreed to cede to Persia the eastern part of the country, which was thence called Persarmenia, while the western part was annexed to the Roman empire. Theodosius nominated Arsaces IV., then nominal king of Armenia, governor of the western division; and the Persian king, to conciliate the people, appointed Chosroes III., a descendant of another branch of the Arsacids, governor of the eastern part. The rule of the Arsacids in Persarmenia ended with Ardashes IV., who was dethroned by Bahram V. of Persia in 428; and from that date Armenia ceased to be a kingdom, and was ruled till 632 by Persian *marzbans* or governors. The Persians had all along endeavoured to subvert Christianity, and for that purpose had recourse to the most cruel persecutions. Frequent insurrections were the consequence, one of the most remarkable being that which was led by Vartan (see Neumann's *History of Vartan, by Elisæus,* 1830). From 632 till 839 Armenia was the scene of almost incessant struggles between the Greeks and Mahometans, while its own native princes added to the confusion by their rivalries and strife.

Pagratid dynasty, 743-1079.

Ashod, a member of the Pagratid family, which claimed to be of ancient Jewish origin, became master of Central and Northern Armenia about 743, and, being recognised by the caliphs as an independent prince, founded a dynasty which continued till 1079, when Cakig II was assassinated, and his kingdom incorporated with the Greek empire.

Ardzrunian dynasty, 908-1080.

Another family, which claimed the parricide sons of Sennacherib as its founders, held possession of the province of Vasburagan and some of the neighbouring territory, and maintained its independence till 1080, when it likewise succumbed to Byzantium.

Merwanid dynasty, 984-1085.

During the same period the district north-west of lake Van was held by the Mussulman race of the Merwanids,—called by the Armenians the princes of Abrahuni,—who gave a nominal submission now to the Byzantine government and now to the sultans.

Rhupenian dynasty, 1080-1393.

Rhupen (Ruben), a relative of the last king of the Pagratid dynasty, retired to the north of Cilicia, and founded in the shelter of the Taurus a small principality, which gradually extended its boundaries to the Mediterranean, and became known as the kingdom of Lesser Armenia. The Rhupenians entered into alliance with the Crusaders, and formed, along with the kings of Cyprus, the last bulwark of Christianity in the East. They welcomed as allies the Mongolian hordes that overran Asia in the 13th century, and shared in the hostility and vengeance of the Mamelukes. The last king of the family, Leon, or Ghevond VI., was taken prisoner in spite of a vigorous defence at Gaban in 1375, and, after six years of captivity in Egypt, wandered through Europe till his death, at Paris, in 1393. (See Langlois, *Essai sur les rois de la dyn. Roupénienne*, St Petersb., 1860; *Documents pour servir à l'hist. des Lusignans de la P. Arm.*, 1859; *Le Trésor des chartes d'Arménie*, 1863.)

About the middle of the 14th century the Kurds had possession of the south of Armenia, the Persians of the north, and the Ottomans of the west. The whole was subjected to the sway of Timour, of whose cruelties a graphic account has been left by the Armenian, Thomas of Medzoph (see Nève's *Etude sur Thomas de Medzoph*). It was mainly governed by Persian officials during the next century, the only national authority being the patriarch. In 1604 Shah Abbas, in his contest with Ahmed I., laid the whole country waste, and forcibly transplanted about 40,000 of the inhabitants into Persia, where they settled principally in Ispahan and New Julfa, as they fondly called the city which they founded Since then the Armenians have had no political position as a nation, though they continue to form an important and valuable portion of the population in Russia, Turkey, and Persia, and their colonies have spread into almost all quarters of the globe. It was calculated, about 1850, that there were approximately four millions of Armenians in the world, of whom 2,500,000 were inhabitants of the Ottoman empire, 1,200,000 of the Russian empire, 25,000 in the empire of Austria, 150,000 in Persia and Azerbijan, 25,000 in continental India and the Archipelago of Asia, and the remaining 100,000 scattered in various countries (Dulaurier). According to a recent statistician of Turkey (Lejean), there are 400,000 Armenians in the European part of the empire, of whom more than 200,000 are in Constantinople itself. Originally a brave and warlike people, they have become distinguished for their peaceful character and their submissiveness to the government of every country in which they live. (See the articles of Dulaurier and Prince Dadian in *Revue des D. Mondes*, 1854 and 1867.)

ARMENIAN CHURCH, THE, is one of the oldest Eastern Christian churches not in communion with the orthodox Greek Church or with the Church of Rome.

1. *History.*—This is divided into three periods, from 34 to 302 A.D., from 302 to 491, and from 491 to the present time. (1.) The first period is mainly legendary. The Church of Armenia claims an older than apostolic foundation. Our Lord, they say, corresponded by letter with Akbar, prince of Ur or Orfa; and the apostle Thaddeus, accompanied by Bartholomew and Judas, preached the gospel, and founded a Christian church in Armenia as early as the year 34 A.D. But whatever the value of these primitive traditions, Armenia could hardly be said to have a church at all during this first period, although there are evident traces of Christian worship in the country at a very early time. (2.) The historical founder of the Armenian Church was S. Gregory, called the "Illuminator." He was a prince of the reigning family of the Arsacidæ, who, having been converted to Christianity, was eager for the conversion of his countrymen. In his missionary work he endured many persecutions, but at last managed to win over the king of Armenia and a considerable portion of his subjects. At the king's desire Gregory went to Cæsarea, or Sis, and was there consecrated bishop of Armenia (302 A.D.) His successors afterwards assumed the title of Patriarch, subsequently Catholicos, and under their rule the infant church grew and prospered. It had to struggle against the opposition of heathen fellow-countrymen and Persian conquerors, but it succeeded in establishing itself in the hearts of the people. The Bible was translated in 410 A.D.; the Liturgy, said to be very old, was improved; and the Armenian bishops took part in several of the synods of the church, notably in the third œcumenical council (Ephesus, 431 A.D.) About 450 A.D. the Armenian Church suffered a severe persecution, which prevented any of the bishops being present at the fourth œcumenical council (Chalcedon, 451 A.D.), at which Eutyches and his followers, the extreme opponents of Nestorius, were condemned. The Armenian Church never accepted the decisions of the Council of Chalcedon, and, in 491 A.D., the patriarch, in full synod, solemnly annulled them. This act led to the separation of the Armenian from the orthodox Greek Church. (3.) The period of schismatic existence divides into three—(*a*), from 491 A.D. to the middle of the 15th century; (*b*), from the middle of the 15th to the middle of the 18th centuries; (*c*), from 1746 down to the present time. It is difficult to account for the schism of the Armenian Church; according to common report, the Armenians were Eutychians, and were virtually cut off from the church when the Council of Chalcedon condemned that heresy, but their own account of the matter in their authoritative documents is very different. They allege that they were misled by false reports when they annulled the fourth council; that it was reported to them that the council had decided in favour of the Nestorian heresy, and that this mistake was confirmed by a letter to the patriarch upon the subject from the bishop of Rome, in which certain words were used which might easily be interpreted in the Nestorian sense. The Patriarch Narses, in his letter to the Emperor Manuel Comnenus, in 1166, distinctly repudiates the Eutychian heresy, but it is to be noted that, in defending the doctrinal views

of his church, he employs the somewhat vague terms in use before the Council of Chalcedon, not those stricter definitions which were in use afterwards; he employs σύμμιξις, for instance, in its pre-Chalcedonian meaning, not ἕνωσις. However occasioned, the separation was gradual; Armenian bishops attended the 5th, 6th, and 7th œcumenical councils (2d of Constantinople, 553; 3d of Constantinople, 680; 2d of Nicæa, 788), and the church acknowledges the decrees of those councils as binding. Cut off from the Eastern Church, the Armenian bishops became all the more closely identified with their native country, and kept alive patriotic feeling in times of great national distress. In spite of many national calamities, foreign domination, internal dissensions, and even banishment, the Armenian Church preserved its character, doctrine, and discipline until the middle of the 15th century, when great dissensions arose which resulted in a schism. These quarrels were occasioned by Jesuit missionaries, who endeavoured to make the Armenians adopt the doctrine, liturgy, and ceremonies of the Roman Church. They succeeded in prevailing upon a great number of the adherents of the Armenian Church to separate from the community and join the communion of Rome. The Catholic Armenians, as they are called, first became a separate community towards the end of the 16th century; their existence has proved a source of great weakness to the orthodox church, and through their exertions the old persecutions were revived. This state of matters went on until the middle of the 18th century, when the patriarch sought and obtained the intervention of Peter the Great of Russia. Since then the Armenian Church has found shelter under the protection of Russia. There is a reformation now going on in the Armenian Church, and a Reformed Church has arisen, which seeks to ally itself with the Calvinist Churches of Europe and America.

2. *Doctrines.*—These are almost identical with those of the orthodox Greek Church. The Armenians accept the first three, and the fifth, sixth, and seventh œcumenical councils, denying that of Chalcedon only, but, as has been explained, they, in their authoritative documents, reject the Eutychian heresy, which that council was called to condemn. The chief source of information as to the doctrine is contained in the letter of Narses above referred to. They reject the Western addition of *filioque* to the Nicene Creed, and deny the distinctive doctrines of the Roman Church.

3. The *Liturgy* is said to date from the 1st century, and to have been founded on that of the Church of Jerusalem. St Gregory remodelled it, and introduced the Nicene Creed, using that edition which contains the damnatory clause, and adding a conclusion of his own. Prayers of John Chrysostom and of Basil the Great were introduced in 430 A.D. Prayers are said for the dead, and entreaty is made for the pardon of their sins, but the church does not believe in purgatory, nor admit of indulgences. The holy days are Sundays, the chief feasts observed in the Eastern Church, and ten national saints' days. Christmas is celebrated on the 6th of January, on the day of the Epiphany, and not on the 25th of December.

4. *Sacraments.*—The Church of Armenia has the seven sacraments: baptism, confirmation, the eucharist, penance, ordination, marriage, and extreme unction. *Baptism* is by immersion; the child is immersed three times; it is then anointed with holy oil, is confirmed, and partakes of the eucharist in both elements. *Confirmation* is administered to children immediately after baptism. The *eucharist* is administered in both elements to all members of the church; the bread is always unleavened, and the wine is not mixed with water. Confession must precede the partaking of the eucharist, save in the case of children under seven years of age. *Penance* consists of confession and fasting. *Ordination* is by anointing with the holy oil. The *marriage service* is almost the same as in the Greek Church. In *extreme unction* only priests are anointed with oil. Laity have the prayers said over them, but are not anointed.

5. *The Clergy.*—There is the threefold order—bishops, priests, and deacons; and there are three degrees of episcopal rank—the archbishops (chief among whom is the patriarch or catholicos), the bishop, and the vartabed, or doctor of theology, who has frequently charge of a diocese, with episcopal functions. The clergy are further divided into the black and the white. The black clergy are monks, and are alone eligible for the higher clerical offices; the white clergy include the parish priests and lower clergy. The clergy may marry before ordination, but not after; and a priest's widow is not allowed to remarry. The priesthood is hereditary. During his father's or grandfather's lifetime the heir may follow a secular calling; but he must leave this and enter the priest's office on the death of the priest he is heir to. There are four patriarchs, who have their seats at Constantinople, Jerusalem, Sis, and Etchmiadzin. The clergy of all ranks are supported entirely by the free-will offerings of the people.

Authorities:—*The Life and Times of S. Gregory the Illuminator*, translated by S. C. Malan, 1868. (This is a translation of authoritative papers, and includes a short summary of the state of the Armenian Church. It is founded on authoritative documents.) *The Divine Liturgy of the Armenian Church*, transl. by S. C. Malan, Lond. 1870 (very carefully done). *Histoire, Dogmes, Traditions et Liturgie de l'Eglise Arménienne*, Paris, 1855 (fuller, but not so accurate). *Codex Mysterii Missal Armenorum seu Liturgia Armena*, Rome, 1677 (Lat. and Armen. Later editions of the Liturgy published at Rome belong to the Catholic Armenian Church, and are worthless). (T. M. L.)

ARMENIAN LANGUAGE. The Armenian or Haikan language is an offshoot of the Iranian branch of the Indo-Germanic family of languages. Its earliest stage is probably represented in the cuneiform inscriptions of Van, on which see Hincks, in *Jour. R. Asiatic Soc.*, vol. ix. (1848), and Mordtmann. in *Zeitschrift d. deutschen morgenl. Gesellschaft*, vol. xxvi. (1872). The existing literature of the Armenians dates from the 4th century, and is essentially and exclusively Christian. The translation of the Old Testament by Sahag Bartevatsi, and of the New by Miesrob, are among its oldest monuments. The dialect in which this version is written, and in which it is still publicly read in their churches, is called the old Armenian. The modern Armenian not only departs from the elder form by dialectic changes in the native elements of the language itself, but also by the great intermixture of Persian and Turkish words, which has resulted from the conquest and subjection of the country, and by the character of inversion in the structure of its sentences. Of its two principal dialects,—the Western, spoken in Constantinople and Asia Minor, and the Eastern, spoken by the Armenians scattered over Tartary, Persia, and India,—the latter approaches more nearly to the idiom of the ancient language. According to Philostratus (*Vita Apollonii*, ii. 2), the Armenians had an alphabet of their own in the 2d century A.D., of which, however, no traces remain. The invention of the present alphabet is ascribed to Miesrob at the beginning of the 5th century; it is probably an amplification of the previous one upon the Greek system of arrangement, and consists of thirty-eight letters, the two last of which, ô and f, were added after the 12th century. The order of writing is from left to right. The capital letters are used in inscriptions, and at the beginning of sentences and proper names. As to its phonetic elements, the Armenian language is rough and consonantal, with the accent on the last syllable. It possesses no grammatical gender, except that a masculine is sometimes made feminine by the addition of *uhi*, and that the words for *man* and *woman* may be prefixed to nouns to express their natural gender; there is no dual. The declension is divided into vowel and consonantal declensions, each again being subdivided into strong and weak There are seven cases, including an instrumental. The nine demonstrative pronouns are regulated by the demonstrative letters *s*, *t*, *n*, the first of which expresses proximity, the second lesser, and the last greater distance. The verb has four conjugations, according to the class vowels, *e*, *a*, *u*, *i*, and four tenses,—present, imperfect, aorist, and future, the last two having two forms. In its syntactical structure the old Armenian resembles most nearly the classical Greek. The best and most recent *Grammars* are by H. Petermann (Berlin, 1872), and M. Lauer (Vienna, 1869); *Dictionaries* by Aucher and Brand (2 vols., Venice, 1821), and by A. Calfa (Paris, 1861), which comprises also the modern dialects. A good Grammar of the modern Armenian (Western dialect) is that of E. Riggs (Constantinople, 1856). There is an essay on the dialect of Tiflis, by H. Petermann, in *Abhandlungen der K. Academie der Wissenschaften*, Berlin, 1867. The best recent surveys of Armenian literature are by H. G. O. Dwight (*Jour. Amer. Or. Soc.*, iii.) and M. Patcanian (*Mélanges Asiatiques*, iv.) See also, by the last-mentioned writer, "Recherches sur la formation de la langue Arménienne," in *Journal Asiatique*, August and September 1870.

ARMENIAN LITERATURE. With the exception of a few fragments incorporated in later writers, the pre-Christian literature of Armenia has totally perished. The early Armenians seem to have possessed a body of traditional and historical songs analogous to the *Shah-nameh* of Persia, the memory of which lingered long among the common people, especially in the province of Koghten. Portions of these have been preserved by Moses of Khorene, and investigated by several modern scholars (see *Vebk Hnuin Hayasdani*, i.e., *Chants hist. et pop. de l'Ancienne Arménie*, J. B. Emin, Moscow, 1850; Dulaurier, *Rev. des D. Mondes*, 1852, vol. xiv.; "Etudes sur les chants hist. de l'anc. Arménie," in *Journal Asiatique*, 1852). With the introduction of Christianity a great development of literary activity took place, which chiefly expended itself, however, in translations from the Syriac and Greek. Armenian students were found in Athens and Byzantium, Alexandria and Rome, and some of them attained celebrity in their chosen pursuits. To this tendency we owe the preservation, in Armenian, of many works that have perished in their original languages. Such are the Chronicle of Eusebius, some of the works of Philo, Bardesanes, Faustus of Byzantium, Lerubna of Edessa, &c. (see Wenrich, *De auctorum Græcorum versionibus Arabicis, Armeniacis, &c.*, Leipsic, 1842). The 5th century was one of the most flourishing periods of Armenian literature. It was then that Miesrob accomplished that modification and development of the Armenian alphabet which has frequently procured him the honour of being regarded as its inventor (see Fr. Muller, *Ueber den Ursprung der Armenischen Schrift*, 1865). The Old Testament was translated from the Septuagint by Isaac or Sahak, the patriarch (critical edition, Ven. 1805). These learned men were succeeded by a number of worthy disciples, such as Esnig of Golp (Koghb), Goriun the biographer of Miesrob, and David the Invincible, a keen student of Greek philosophy, who has left us *Philosophical Definitions* and translations from Aristotle (see "La vie et les ouvrages de David le phil. Armén.," by Neumann in *Journal Asiatique*, 1829). Yeghishe or Elisæus wrote a very popular account of the wars of Vartan against the Persians, which has been frequently translated (Neumann, London. 1830). Moses of Khorene is one of the most important as well as best known historians of his native country. In the 6th century all connection with the centres of Greek culture being cut off by the Persian monarchs, Armenian literature became almost extinct. In the 7th century John the Mamigonian continued Zenob's *History of Daron* (Taron); Sebeos composed a history of Heraclius; Ananias of Shirag was the author of astronomical works, and Theodorus and Sahak wrote upon theological subjects. Among the writers of the 8th century the chief place is held by John of Osdin and Stephanus of Siunia; and in the 9th century we find John the Catholikos, Thomas Ardzruni, and Miesrob of Hayotz-dsor. In the 10th century, Khosrov the Great, Ghevond or Leontius the Presbyter, Gregory of Narek, Moses of Kalkand, and Stephanus Asolik (Assoghik) may be mentioned; and in the 11th, Aristakes of Lastiverd, a national historian, and Matthew Yeretz (*i.e.*, the Presbyter) of Edessa, the biographer of Chrysostom.

The 12th and 13th centuries form a second great period of Armenian literature, during which the influence of Syriac is again perceptible. Gregory Magistros, who introduced the Arabic system of versification into his native language, Narses of Lampron, Mekhitar Kosh (see *Journ. Asiat.*, 1841), John Vanacan (*i.e.*, the Monk), Vardan the Great (*Journ. Asiat.*, 1867), Vahram, and Sempad, are a few of the numerous writers of note. From the 14th to the 18th century there is a falling off, the most important work, perhaps, being Thomas of Medzoph's *History of Timour*. In the 18th century a revival took place, which was mainly due to the Mekhitarists of Venice (see Langlois, *Notice sur le couvent Arménien de l'île Saint-Lazare de Venise*, Paris, 1863), and since then Armenian literature has acquired a development which is remarkable in the absence of national unity. Printing presses have been established in most of the cities where Armenians are numerous, the ancient writers have been published and studied, the vernacular literature has been enriched both by original productions and translations, and magazines and newspapers have been established in many of the centres of Armenian activity. The study of the Armenian language and literature by the savants of Western Europe has shared in the general development of Indo-European philology. The earlier labours of Rivola (1633), Villote, La Croze, Osgan, Villefroy, and Freret have been almost completely eclipsed by such men as Saint Martin (an Armenian by race), Dulaurier, Langlois, Boré, and Prudhomme in France; Nève in Holland; Emin, Patcanian, and Brosset in Russia; and Windischmann, Marle, Spiegel, Justi, Neumann, and Petermann in Germany.

See Somal's *Quadro della storia let. di Arm.*; Karikin, *Hist. de la lit. Arm.*; Patcanian, "Cat. de la lit. Arm.," in *Mélanges Asiat.*, vol. iv. Petersb., 1860; Neumann's *Versuch einer Gesch. der Arm. Lit.*; Alishan's *Tableau succinct de l'hist. et de la lit. de l'Arm.*, 1860; Hamachod's *Chronological succ. of Arm. Patriarchs* (in Armenian).

ARMENIAN VERSION. The Armenian version of the Bible was undertaken in the year 410 by Miesrob, with the aid of his pupils Joannes Ecclensis and Josephus Palnensis. It appears that the patriarch Isaac first attempted, in consequence of the Persians having destroyed all the copies of the Greek version, to make a translation from the Peshito; that Miesrob became his coadjutor in this work; and that they actually completed their translation from the Syriac. But when the above-named pupils, who had been sent to the ecclesiastical council at Ephesus returned, they brought with them an accurate copy of the Greek Bible. Upon this Miesrob laid aside his translation from the Peshito, and prepared to commence anew from a more authentic text. Imperfect knowledge of the Greek language, however, induced him to send his pupils to Alexandria to acquire accurate Greek scholarship; and, on their return, the translation was accomplished. Moses of Khorene, the historian of Armenia, who was also employed, as a disciple of Miesrob, on this version, fixes its *completion* in the year 410; but he is contradicted by the date of the Council of Ephesus, which necessarily makes it subsequent to the year 431. In the Old Testament this version adheres closely to the LXX., but, in the book of Daniel, it has followed the version of Theodotion. Its most striking characteristic is, that it does not follow any known recension of the LXX. Although it more frequently agrees with the Alexandrine text, in readings which are peculiar to the latter, than it does with the Aldine or Complutensian text, yet, on the other hand, it also has followed readings which are only found in the last two. Bertholdt accounts for this mixed text by assuming that the copy of the Greek Bible sent from Ephesus contained the Lucian recension, that the pupils brought back copies according to the Hesychian recension from Alexandria, and that the translators made the latter their standard, but corrected their version by aid of the former. The version of the New Testament is equally close to the Greek original, and also represents a text made up of Alexandrine and Occidental readings. This version was afterwards revised and adapted to the Peshito, in the 6th century, on the occasion of an ecclesiastical union between the Syrians and Armenians. Again, in the 13th century, an Armenian king, Hethom or Haitho, adapted the Armenian version to the Vulgate, by way of smoothing the way for a union of the Roman and Armenian churches. Lastly, the bishop, Uscan, who printed the first edition of this version at Amsterdam in 1666, is also accused of having interpolated the text, by adding all that he found the Vulgate contained *more* than the Armenian version. The existence of the verse 1 John v. 7, in this version, is ascribed to this supplementary labour of Uscan. It is clear from what has been said, that the critical uses of this version are limited to determining the readings of the LXX. and of the Greek text of the New Testament which it represents, and that it has suffered many alterations which diminish its usefulness in these respects.

ARMENTIÈRES, a well-built and flourishing town, in the department of Nord in France, on the Lys, nine miles N.W. of Lille. It carries on considerable manufactures of leather, cotton, cloth, linen, lace, soft-soap, beet-root sugar, salt, &c. Situated as Armentières is on the frontier, its annals are full of instances of military occupation and pillage, from the 14th century downwards. Population, 15,579.

ARMFELT, Gustav Mauritz, Baron, afterwards **Count**, eldest son of a Finnish nobleman, was born at Juva in 1757. He entered the army and gained the favour of Gustavus III., who appointed him to a post in the service of the Crown Prince, and afterwards made him general of a division of the army in the war against Russia. He was successful in his military operations, and also materially aided the king in quelling a conspiracy of the officers. In 1790 he signed the treaty of peace at Verela; and two years later, when Gustavus was mortally wounded by an assassin, Armfelt was named by him governor of Stockholm. But the regent Charles, the late king's brother, was not well disposed towards him, and he took an opportunity to leave the country as ambassador to Naples. While there he entered into a conspiracy to depose the regent. This was discovered; he was outlawed and condemned to death, and his associates were severely punished. The accession of Gustavus IV. restored him to his honours, and after the revolution of 1809, by which the ex-regent became king, he was made president of the military council. Being suspected of having a share in the poisoning of the prince of Augustenburg, he fled from Sweden and took refuge at the Russian court, where he received the highest honours. He died in 1814 at Tzarskoe-Selo.

ARMINIUS, James, a distinguished Dutch theologian, author of the modified Reformed theology that receives from him its name, was born at Oudewater, South Holland, 1560. Arminius is a Latinised form of his family name Hermanns or Hermannson. His father, a cutler, died while he was an infant, leaving a widow and three children. Theodore Æmilius, a priest, who had turned Protestant, adopting James, removed with him to Utrecht, but died when his charge was in his fifteenth year. Rudolph Snellius, the mathematician, a native of Oudewater, then a professor at Marburg, happening at the time to visit his early home, met Arminius, saw promise in him, and undertook his maintenance and education. But hardly was he settled at Marburg when the news came that the Spaniards had besieged and taken Oudewater, and murdered men, women, and children, sparing only certain matrons and maids, "who had been sold by auction to the soldiers at two or three dollars each." Arminius hurried home, but only to find all his relatives slain. In February the same year (1575), the university of Leyden had been founded, and was becoming a rallying point and nursery for the nascent literary genius, theological activity, and scholarship of the country. Arminius seized the opportunity thus afforded of pursuing his studies at home. The six years he remained at Leyden (1576–82) were years of active and innovating thought in Holland. The War of Independence had started conflicting tendencies in men's minds. To some it seemed to illustrate the necessity of the State tolerating only one religion, but to others the necessity of the State tolerating all. Richard Koornhert argued, in private conferences and public disputations, that it was wrong to punish heretics, and his great opponents were, as a rule, the ministers, who maintained that there was no room for more than one religion in a State. Casper Koolhaes, the heroic minister of Leyden—its first lecturer, too, in divinity—pleaded against a too rigid uniformity, for such an agreement on "fundamentals" as had allowed Reformed, Lutherans, and Anabaptists to unite. Leyden had been happy, too, in its first professors. There taught in theology William Feugueræus, a mild divine, who had written a treatise on persuasion in religion, urging that as to it "men could be led, not driven;" Lambert Danæus, who deserves remembrance as the first to discuss Christian ethics scientifically, apart from dogmatics; John Drusius, the Orientalist, one of the most enlightened and advanced scholars of his day, settled later at Franeker; John Kolmann the younger, best known by his saying that high Calvinism made God "both a tyrant and an executioner." Snellius, Arminius's old patron, now removed to Leyden, expounded the Ramist philosophy, and did his best to start his students on the search after truth, unimpeded by the authority of Aristotle. Under these men and influences, Arminius studied with signal success; and the promise he gave induced the merchants' guild of Amsterdam to bear the further expenses of his education. In 1582 he went to Geneva, studied there awhile under Theodore Beza, but had soon, owing to his active advocacy of the Ramist philosophy, to remove to Basle. After a short but brilliant career there he returned to Geneva, studied for three years, travelled, in 1586, in Italy, heard Zarabella lecture on philosophy in Padua, visited Rome, and, open-minded enough to see its good as well as its evil, was suspected by the stern Dutch Calvinists of Popish leanings. Next year he was called to Amsterdam, and there, in 1588, was ordained to the ministry. He soon acquired the reputation of being an elegant preacher and faithful pastor. He was commissioned to organise the educational system of the city, and is said to have done it well. He greatly distinguished himself by fidelity to duty during a plague that devastated Amsterdam in 1602. In 1603 he was called to a theological professorship at Leyden, which he held till his death in 1609.

Arminius is best known as the founder of the anti-Calvinistic school in Reformed theology, which created the Remonstrant Church in Holland (see REMONSTRANTS), and contributed to form the Arminian tendency or party in England. He was a man of mild and liberal spirit, broadened by varied culture, constitutionally averse to narrow views and enforced uniformity. He lived in a period of severe systematising. The Reformed strengthened itself against the Roman Catholic theology by working itself, on the one hand, into vigorous logical consistency, and supporting itself, on the other, on the supreme authority of the Scriptures. Calvin's first principle, the absolute sovereignty of God, had been so applied as to make the divine decree determine alike the acts and the destinies of men; and his formal principle had been so construed as to invest his system with the authority of the source whence it professed to have been drawn. Calvinism had become, towards the close of the 16th century, supreme in Holland, but the very rigour of the uniformity it exacted provoked a reaction. Richard Koornhert could not plead for the toleration of heretics without assailing the dominant Calvinism, and so he opposed a conditional to its unconditional predestination. The two ministers of Delft, who had debated the point with him, had, the better to turn his arguments, descended from the supralapsarian to the infralapsarian position, *i.e.*, made the divine decree, instead of precede and determine, succeed the fall. This seemed to the high Calvinists of Holland a grave heresy. Arminius, fresh from Geneva, familiar with the dialectics of Beza, appeared to many the man able to speak the needed word, and so, in 1589, he was simultaneously invited by the ecclesiastical court of Amsterdam to refute Koornhert, and by Martin Lydius, professor at Franeker, to combat the two infralapsarian ministers of Delft. Thus led to confront the questions of necessity and free will, his own mind became unsettled, with the result, that the further he pursued his inquiries the more he was inclined to assert the freedom of man and limit the range of the unconditional decrees of God. This change in doctrinal belief became gradually more apparent in his preaching and in his private conferences with his clerical associates, and occasioned much controversy in the ecclesiastical courts. The controversy was greatly embittered, and the differences correspondingly sharpened, by his appointment to the professorship at Leyden. He had as colleague Francis Gomarus, a strong supralapsarian, perfervid, irrepressible; and their collisions, personal, official, political, tended to develop and define their respective positions. Arminius died, worn out by uncongenial controversy, before his system had been elaborated into the logical consistency it attained in the hands of his celebrated successor, Simon Episcopus, but though inchoate in detail, it was in its principles clear and coherent enough. These may be thus stated:—

1. The decree of God is, when it concerns His own actions, absolute, but when it concerns man's, conditional, *i.e.*, the decree relative to the Saviour to be appointed and the salvation to be provided is absolute, but the decree relative to the persons saved or condemned is made to depend on the acts—belief and repentance in the one case, unbelief and impenitence in the other—of the persons themselves.

2. The providence or government of God while sovereign, is exercised in harmony with the nature of the creatures governed, *i.e.*, the sovereignty of God is so exercised as to be compatible with the freedom of man.

3. Man is by original nature, through the assistance of divine grace, free, able to will and perform the right; but is in his fallen state, of and by himself, unable to do so; needs to be regenerated in all his powers before he can do what is good and pleasing to God.

4. Divine grace originates, maintains, and perfects all the good in man, so much so that he cannot, though regenerate, conceive, will, or do any good thing without it.

5. The saints possess, by the grace of the Holy Spirit, sufficient strength to persevere to the end in spite of sin and the flesh, but may so decline from sound doctrine as to cause divine grace to be ineffectual.

6. Every believer may be certain or assured of his own salvation.

7. It is possible for a regenerate man to live without sin.

Arminius's works are mostly occasional treatises drawn from him by controversial emergencies, but they everywhere exhibit a calm, well-furnished, undogmatic, and progressive mind. Characteristic are such sayings as these in letters to his friend, Uitenbogaert:—"Truth, even theological truth, has been sunk in a deep well, whence it cannot be drawn forth without much effort." "I should be foolish were I to concede to any one so much of right in me, as that he should be able to disturb me as often as he had a mind. Be this my brazen wall, a conscience void of offence. Forward let me still go in my search after truth, and therein let me die with the good God on my side, even if I must needs incur the hatred and ill-will of the whole world." He was essentially an amiable man, who hated the zeal for an impossible orthodoxy that constrained "the church to institute a search after crimes which have not betrayed an existence, yea, and to drag into open contentions those who are meditating no evil." His friend Peter Bertins, who pronounced his funeral oration, closed it with these words,—"There lived a man whom it was not possible for those who knew him sufficiently to esteem; those who entertained no esteem for him are such as never knew him well enough to appreciate his merits."

The works of Arminius (in Latin) were published in a single quarto volume in 1631. The first volume of an English translation, with copious notes, by James Nichols, was published in 1825, the second in 1828, but the third and concluding volume is still due. A life was written by Casper Brandt, son of Gerard Brandt, the historian of the Dutch Reformation, and published in 1724; republished and annotated by the historian Mosheim in 1725; translated into English by the Rev. John Guthrie, and published in 1854.

(A. M. F.)

ARMISTICE, a temporary suspension of hostilities by mutual agreement between two nations at war, or their respective forces. An armistice may be either general or particular: in the first case, there is a complete cessation of hostile operations in every part of the dominions of the belligerent powers; in the second, there is merely a temporary truce between two contending armies, or between a besieged fortress and the force besieging it. A general armistice cannot be concluded by the commanders-in-chief unless special authority has been previously delegated to them by their respective governments; otherwise, any arrangement entered into by them requires subsequent ratification by the supreme powers of the states. A partial truce may be concluded by the officers of the respective powers, without any special authority from their governments, wherever, from the nature and extent of the commands they exercise, their duties could not be efficiently discharged without their possession of such a power. The conduct of belligerent parties during an armistice is regulated by the following general conditions, which, however, may be set aside by special agreement:—(1.) Each party may do, within the limits prescribed by the truce, whatever he could have done in time of peace. For example, he can raise troops, collect stores, receive reinforcements, and fortify places that are not actually in a state of siege. (2.) Neither party can take advantage of the armistice to do what he could not have done had military operations continued. Thus he cannot throw provisions or reinforcements into a besieged town, and neither besiegers nor besieged are at liberty to repair their fortifications or erect new works. (3.) All things contained in places, the possession of which was contested, must remain in the state in which they were before the armistice began. Any infringement by either party of the conditions of the truce entitles the other to recommence hostile operations without previous intimation.

ARMORICA. The Armorici were, in Cæsar's time, the Celtic inhabitants of the coast from the Loire to the Seine. The word appears to be composed of "*ar*," near, and "*mor*," the sea, and would originally be applicable to any maritime population. It is said to be akin to "Morini," and "Pomerania" (Po-more). In the Middle Ages the name Armorica was still further narrowed into an equivalent for Brittany. See Celtic Literature.

ARMS and ARMOUR. The history of arms and armour forms one of the most suggestive chapters in the history of civilisation. The use of stone weapons appears to have been universally characteristic of the earlier, as it is still distinctive of the ruder races of mankind. The forms of the weapons fabricated in this intractable material were of necessity few and simple. The commonest and most widely distributed type is that of the imperforate axe, varying from the roughly-dressed wedge of flint, to the finely-shaped and highly-polished lenticular "celt." They were fabricated of flint, diorite, greenstone, serpentine, indurated clay-slate, in short, of almost every material capable of being worked into the desired form, and of retaining the requisite sharpness of edge. Spear-heads and arrow-points were chipped in flint with such surprising dexterity and skill, that they were nearly as effective as those subsequently fabricated in metals, and not much inferior in form and finish. The highest efforts of the ancient stone-workers culminated in the short leaf-shaped knife-dagger of flint, suggestive of the form which afterwards became the characteristic weapon of the Bronze Age, the leaf-shaped sword. These knife-daggers of flint exhibit considerable variety of form, though always of the same type. They vary also in size, but seldom exceed about 12 inches in length. They are never ground or polished, but delicately chipped to a straight edge, while the flakes are so regularly removed from the convex portions of the blade as to give a rippled or wavy surface, and the corners of the handle are delicately crimped, thus producing an appearance of great beauty and finish.

Fig. 1.—Leaf-shaped flint Dagger.

The Bronze Age.—In the earliest interments in which the weapons deposited with the dead are of other materials than stone, a peculiar form of bronze dagger occurs. It consists of a well-finished, thin, knife-like blade, usually about 6 inches in length, broad at the hilt and tapering to the point, and always riveted to the handle by massive rivets of bronze. It has been found associated with stone celts, both of the roughly-chipped and the highly-polished kind, showing that these had not been entirely disused when bronze became available. A later type of bronze dagger is a broad, heavy, curved weapon, usually from 9 to 15 inches in length, with massive rivets for attachment to an equally massive handle. The leaf-shaped sword, however, is the characteristic weapon of the Bronze Period. It is found all over Europe, from Lapland to the Mediterranean. No warlike weapon of any period is more graceful in form or more beautifully finished. The finish seems to have been given in the mould without the aid of hammer or file, the edge being formed by suddenly reducing the thickness of the metal, so as to produce a narrow border of extreme thinness along both sides of the blade from hilt to point. The handle-plate and blade were cast in one piece, and the handle itself was formed by side plates of bone, horn, or wood, riveted through the handle-plate. There was no guard, and the weapon, though short, was well balanced, but more fitted, however, for stabbing and thrusting than for cutting with the edge. The Scandinavian variety is not so decidedly leaf-shaped, and is longer and heavier than the common British form; and instead of a handle-plate, it was furnished with a tang on which a round, flat-topped handle was fastened, like that of the modern Highland dirk, sometimes surmounted by a crescent-like ornament of bronze. A narrow, rapier-shaped variety, tapering from hilt to point, was made without a handle-plate, and attached to the hilt by rivets like the bronze daggers already mentioned. This form is more common in the British Isles than in Scandinavia, and is most abundant in Ireland. The spear-heads of the Bronze Period present a considerable variety of form, though the leaf-shaped predominates, and barbed examples are extremely rare. Some British forms of this weapon are of great size, occasionally reaching a length of 27 inches. The larger varieties are often beautifully designed, having segmental openings on both sides of the central ridge of the blade, and elaborately ornamented with chevrony patterns of chased or inlaid work both on the socket and blade. Arrow-points are much rarer in bronze than in flint. In all probability the flint arrow-point (which was equally effective and much more easily replaced when lost) continued to be used throughout the Bronze Period. Shields of bronze, circular, with hammered-up bosses, concentric ridges, and rows of studs, were held in the hand by a central handle underneath the boss. The transition period between the Bronze and Iron Ages in Central Europe is well defined by the occurrence of iron swords, which are simple copies of the leaf-shaped weapon, with flat handle-plate previously fabricated in bronze. These have been found associated with articles assigned to the 3d or 4th century B.C.

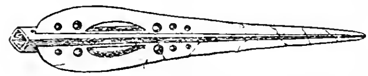

Fig. 3.—Bronze Spear head, length 19 inches.

The Greek Heroic Age.—The Greek sword of the heroic age is described by Homer as double-edged, long, sharp, and trenchant, the blade of bronze, and the hilt and scabbard adorned with gold or silver studs. In the Homeric combats, however, the spear, lance, or javelin always plays the principal part, and the sword is only used when the combatants meet at close quarters, the spear having failed to decide the contest. Both sword and spear appear to have been of the forms which are characteristic of these weapons in the Bronze Age of Central and Northern Europe. The bow of Pandarus is described as made of ibex-horn and strung with sinews. The arrow-head is the only part of the warrior's equipment which Homer expressly describes as of iron, and the mode of its insertion in a split in the head of the shaft, where it was made fast by a ligature of sinew, is precisely that which is still adopted by modern savages with their arrow-points of flint. The defensive armour of the heroic ages was also entirely of bronze. In consisted of helmet, cuirass, greaves, and shield. The helm was sometimes a simple casque, or close-fitting headpiece, but more frequently adorned with crest and plumes. The cuirass of bronze was often elaborately engraved and adorned with gold. The greaves covered the leg to the instep, and were either of bronze or some similar compound metal of great toughness and flexibility. The shield, round or oval in form, is described as of bronze, backed or covered with hide, and decorated with bosses and concentric rings of metal. We have a gauge of the size of Hector's shield in the lines—

> "Hector of the gleaming helm
> Turned to depart; and as he moved along
> The black bull's-hide his neck and ancles smote,
> The outer circle of his bossy shield."
>
> *Il.* vi. 116-118.

Greek Historic Age.—In the early historic ages the characteristic weapons of the Greek armies were determined by the military tactics of the period. The mode of fighting in heavy phalanx necessitated the use of long, heavy spears. The Hoplites when massed in phalanx stood sixteen deep, the men of each rank close together, shield touching shield, the pikes of each line, 21 to 24 feet long, projecting from 2 to 13 feet in front of the foremost rank at equal distances. The shield of the early monuments, though still large, is not nearly so large as that of Hector, usually reaching from the shoulder to the knee, and still retaining its round or oval form and bold convexity. On the early vases the shields are represented as adorned with a great variety of devices. We now find the helm having a lengthened neck-guard, side-guards for the face, frontlet, and prolonged crest, sweeping gracefully over the rounded top of the head-piece and falling down the back. At the time of the Peloponnesian war the linen corselet, so much in favour among the Egyptians, Assyrians, and Asiatics generally, was introduced instead of the heavy cuirass of the Hoplites, and a smaller shield substituted for the larger and heavier one previously in use, while the length of the sword was considerably increased. The light-armed troops were furnished with a light javelin provided with a strap or thong attached to the middle to assist in hurling it. The mounted troops were similarly equipped as to their defensive armour, and furnished with a longer sword, a javelin, and a short dagger.

Egyptian.—The strength of the Egyptian armies in the earliest times consisted of archers, who fought either on foot or from chariots. The Egyptian bow was somewhat shorter than the height of a man. The string was of hide, catgut, or cord. The arrows varied from 24 to 34 inches in length, and were usually of reed, winged with three feathers and pointed with heads of bronze. These were sometimes cast with sockets and sometimes with tangs. Arrow-heads of flint are occasionally found in the tombs along with those of bronze, and Sir Gardner Wilkinson remarks on this, that "flint arrow-heads were not confined to an ancient era, nor were they peculiar to Egypt alone; the Persians and other Eastern peoples frequently used them even in war." The Egyptian archers were provided with a falchion, dagger, mace, or battle-axe, for close combat; their defensive armour consisted of a quilted head-piece and coat, but they carried no shield, which would have been an impediment to the free use of the bow The infantry were classified according to the weapons with which they fought, as spearmen, swordsmen, clubmen, and slingers. The spears were 5 or 6 feet long, with large triangular or leaf-shaped heads of bronze, socketed and fastened to the shaft by a single rivet through the socket. The spearmen fought in close phalanx, and were furnished with shields of a peculiar form, rectangular below and semicircular above, like a round-headed door, about half the height of a man. Their shields were covered with bull's hide, having the hair outwards, strengthened by rims and studs of metal, and furnished with a round sight-hole in the middle of the semicircular upper part. They had quilted helmets, and cuirasses of bronze scales or quilted with bands of metal, but no greaves. The early Egyptian sword was of bronze, straight, double-edged, tapering from hilt to point, and varying from 30 to 36 inches in length. Axes, with short handle and an oblong or crescentic blade, with segmental openings, fastened to the handle and unsocketed, maces and clubs of various forms, and short, leaf-shaped daggers of bronze, were also used.

Assyrian.—The Assyrian sword, as represented on the monuments, resembled the Egyptian, but was worn on the left side, slung in a nearly horizontal position by the waist-belt. The bow was also a favourite weapon with the Assyrians, and lances, spears, and javelins, with oblong, leaf-shaped and unbarbed heads, constantly appear upon the sculptures. The shield was round and convex; the helm frequently conical, truncated or curved forward, and with pieces to protect the neck at the back and sides. Their cuirasses were close-fitting tunics made of many layers of flax, plaited or interwoven, and hardened and cemented with glue,—a species of linen corselet frequently referred to as in use also among the Egyptians, the Greeks, and the Romans.

Etruscan.—The arms and armour of the Etruscans were in the main similar to those of the Greeks. Their cuirasses, however, were provided with overlapping shoulder-guards, a peculiarity not observed in Greek armour. The shields were round and exceedingly convex, the helmets of very various forms, with a general tendency to a deep, bell-shaped contour, adorned with an excessively elevated and elongated crest, and sometimes with alated projections of considerable height, rising from opposite sides near the apex of the helm.

Roman.—The early Roman sword, like that of the Greeks, Egyptians, and Etruscans, was of bronze. We have no direct statement as to its form, but in all probability it was of the leaf-shaped form so universally characteristic of this weapon in bronze. We gather from the monuments that, in the 1st century B.C., the Roman sword was short, worn on the right side, suspended from a shoulder-belt, and reaching from the hollow of the back to the middle of the thigh, thus representing a length of from 22 inches to 2 feet. The blade was straight, double-edged, and obtusely pointed. On the Trajan column (114 A.D.) it is considerably longer, and under the Flavian emperors the long, single-edged *spatha* appears frequently along with the short sword. The characteristic weapon peculiar to the Romans, however, was the *pilum*. The form of this weapon and the mode of using it have been minutely described by Polybius, but his description has been much misunderstood in consequence of the rarity of representations or remains of the *pilum*. It is shown on a monument at St Remi, in Provence, assigned to the age of the first emperors, and in a bas-relief at Mayence, on the grave-stone of Quintus Petilius Secundus, a soldier of the 15th legion. A specimen of the actual weapon is in the museum at Weisbaden. It is a pike with a stout iron head, carried on an iron rod, about 20 inches in length, which terminates in a socket for the insertion of the wooden shaft. As represented on the monuments, the iron part of the weapon is about one-third of its entire length, and its junction with the wooden part of the shaft is fortified by a knob or swelling which is peculiar to this weapon. When used as a javelin at short distances it had a most embarrassing effect. Piercing the shield, the slender iron neck of the weapon bent with the weight of the shaft, which then dragged along the ground, so that the shield was rendered useless for defence. When used at close quarters it not only answered all the purposes of the modern bayonet, but when firmly wielded in both hands it was equally efficient to ward off sword-strokes, which fell harmless upon the long and strong iron neck of the weapon. Polybius states that the legionary receiving the sword-strokes, with cool steadiness, upon his *pilum*, soon turned the swords of the enemy into mere hacked and blunted strigils or skin-scrapers. Vegetius also describes the *pilum* in a modified form as used in the armies of the Lower Empire, and in a still more modified form it reappears as the *angon* of the Franks, to be noticed further on. The defensive armour of the Romans in earlier times resembled that of the Greeks as previously described, and was chiefly of bronze, consisting usually of helmet with crest and cheek-pieces, cuirass of breast and back plates, modelled to the form of the bust, and having a border of leather bands or straps, falling vertically so as to protect the lower part of the body. On the columns of Trajan and Antonine the cuirass proper is given to the chiefs only, the legionaries having their cuirasses of leather or linen, on which are sewn circular plates of metal, with shoulder-pieces and oblong plates descending vertically from the lower border of the cuirass. There are two varieties of shield on the Trajan column,—an oblong, rectangular, and highly convex form, peculiar to the legionaries, and an oval, flattened form borne by the knights and *velites*. In later times the oval shield was assumed by the legionaries. The Roman helmets in the time of the early emperors were simple skull-caps with a hollowed neck-guard, a small bar acting as a visor, and hinged cheek-pieces which fastened under the chin. In the declining days of the empire the helmet became deeper, the shield larger and more varied in form, the length of the sword was greatly increased, and uniformity of weapons and equipment was no longer observed.

Frankish.—The characteristic weapon of the Franks of the Merovingian epoch (450–760 A.D.) was the *francisca* or battle-axe, which they used as a missile. Procopius describes it as having a broad blade and a short haft, and it is said that the blow of an axe when hurled would pierce a shield or kill a man, and that the Franks rarely missed their aim. Agathias, the continuator of Procopius (535 A.D.), says they wear no body armour, few of them even having helmets, but they carry round shields, swords of the length of a man's thigh, axes having double edges, and darts which are used either for throwing or for thrusting. These darts had barbed iron heads, and were used as the

FIG. 4.—Iron head of Angon from a grave at Darmstadt, 38 in. long.

pilum was used by the Romans. When the *angon* was fixed in the enemy's shield the custom of the Frank was to bound forward, place his foot on the end of the dart as it trailed along the ground, thus compelling the enemy to lower his shield, when he killed him with his axe or sword. The Frankish sword was a short, straight, broad-bladed, double-edged weapon, somewhat obtusely pointed, and usually about 30 to 32 inches in length. The sword and *francisca* of Childeric, one of the first of the Merovingian kings (457–481), were discovered in his tomb at Tournay in 1653, and are now in the museum of the Louvre. The sword has a short, straight cross-piece at the lower end of the hilt, and the pommel is of the same form, but smaller. The Carlovingian epoch, though almost devoid of distinctive characteristics as regards the arms in use, is remarkable for the gradual change from infantry to cavalry, and represents the transition to the period of chivalry. The development of the two military orders of the knights or men-at-arms and the common infantry soldiers, serfs or peasants, may be said to have begun in the armies of Charlemagne, and the superior class of fighting men in his time had added to the ordinary equipment of the earlier Franks the helm and coat of mail.

Scandinavian.—The swords of the early Iron Age in Scandinavia are frequently found in the mosses of Schleswig, associated with objects bearing a strongly-marked analogy to those recovered from the graves of our own Pagan Anglo-Saxon ancestors, of the period dating approximately from the 5th to the 7th centuries of the Christian era. They are long, straight, double-edged, and often richly damascened. On the tangs of several of those found at Nydam are the names of the armourers some of which are of the Roman form. The grip of the hilt was circular, usually narrow in the middle, and the cross-pieces above and below were similar in shape. The sheaths were of wooden laths, adorned with tastefully-executed mountings in bronze. On one of the chapes an inscription in the earlier Runic alphabet occurred. Associated with these swords were flat, circular wooden shields, of 22½ to 44 inches diameter, having a single handle under the central boss, and bosses and mountings sometimes of iron, but more frequently of bronze. Helmets were rare, but chain-armour of interlinked iron rings, of alternate rows of riveted and welded rings, was in use. The sword of the early Viking time in Scandinavia was long and heavy, usually double-edged, with strong rectangular cross-piece, narrow grip, and massive square or triangular pommel. In the later Viking time single-edged swords were more common, and the pommel was frequently tri-lobed, and the cross-piece elongated so as to form a decided guard. The shields were usually circular or oval, often painted and adorned with devices, and conical helmets and coats of mail were common.

Anglo-Saxon.—The early Anglo-Saxon sword was usually about 3 feet long, straight, double-edged, broad in the blade, and rounded at the point, with hilt and grip and cross-piece like those of the early Scandinavian swords previously described. As the sword was not carried by any man under the rank of thane, it is not often met with in Anglo-Saxon interments. With them, as with the Franks, it was a horseman's weapon, and the common accoutrement of the infantry was a spear, an axe, a shield, and a *scramasax*, or heavy single-edged knife. The Saxon spear was a narrow, long-bladed weapon, varying greatly in form and dimensions, but generally characterised by the socket being slit or unclosed throughout its length. The axe was narrow-bladed and single-edged, and sometimes peaked at the back. The shield, which was circular or oval in form, was of wood, covered with leather, and furnished with a high conical boss, often terminating in a pipe or a button. Anglo-Saxon warriors of the 10th century are represented in the manuscripts as wearing hauberks of mail and rounded casques. The Ælfric manuscript, of the end of the 11th century, shows the tri-lobed sword-hilt and round shield.

Norman.—The arms and armour of the Normans at the period of the conquest of Normandy were, of course, Scandinavian. The Norman arms of the period of the conquest of England are portrayed on the Bayeux tapestry. The sword is still of the Scandinavian type, long, straight, double-edged, and somewhat tapering, and round or obtusely pointed with cross piece and pommel. The horsemen are armed with long lances as well as swords. On the tapestry the Normans are represented as well provided with archers and cavalry, of which the Saxons are apparently destitute. Maces and clubs appear also among the weapons; and axes, with shafts from 4 to 6 feet in length, appear in the hands of both Normans and Saxons. The Norman shield is large and kite-shaped, provided with arm-strap and handle, and adorned with emblazonments of badges or devices. Few examples of the older circular shield appear on the tapestry, and these few are Saxon. The body armour consisted of a long hauberk, ringed or trellised, with divided skirt, and having the hood and body in one piece. The helmet was deep, conically topped, and furnished with a nasal.

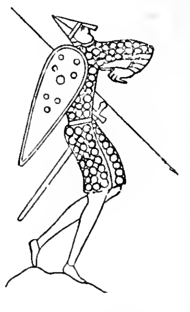

FIG. 5.—From the Bayeux tapestry.

English after the Norman Conquest.—The armour in use in England since the period of the Norman Conquest may be briefly divided into four groups, each associated with its own historical period. True mail armour of interlinked rings was generally adopted in the time of the Crusades, and its use extended to about the beginning of the 14th century. Towards the close of the 12th century the long plaited or mailed skirt, divided at the bottom, as we see in the Bayeux tapestry, had been superseded by a short-sleeved tunic, generally of chain-mail, reaching only to the knees, but sometimes covered with variously-shaped plates of metal. This short hauberk was confined by a belt about the waist, and furnished with a hood or coif, over which a close-fitting helm was worn. In the 13th century there was less uniformity of military equipment. The hauberk was again lengthened to the middle of the leg, and had a coif to cover the head, over which the massive helm, with or without a nasal, was worn, sometimes with a movable visor. The sleeves of the hauberk were prolonged, and mittens added to protect the hands; the lower limbs were covered with mail, the coverings above the knee being called *chaussons*, and those below the knee *chausses*. The sword was long, straight, and pointed, generally with a short recurved guard and rounded pommel. The shield was small, triangular, or heater-shaped; the helm massive, high, and flat-topped. After the middle of the 13th century secondary defences of plate for the protection of the joints began to be introduced; the hauberk was shortened, the mittens of mail were divided into fingers, the helm was often rounded at the top, and greaves and shoulder-plates were introduced. The period of mixed mail and plate armour extends from about 1300 to about 1410. The introduction of secondary defences of plate for the weaker and more exposed parts of the mail-suit gradually changed the character of the armour, until it produced the complete panoply of plate-armour. In the first half of the 14th century the sleeves of the hauberk were shortened, *demi-brasarts* were introduced for the protection of the back of the upper arm, and *vambraces* worn on the front of the lower arm, *roundles* were added in front of the shoulder-joints and at the elbows, and the greaves or *jambarts* were continued over the feet in laminated plates. The *bassinet* was now worn beneath the huge sugar-loafed helm, and had a *camail*, or curtain of mail, descending down the back for the protection of the neck, which subsequently assumed the form of a close-fitting tippet. By the middle of the century splinted armour had become common, and the cuirass with gussets of mail appears. As the second half of the century advanced, the arms and legs were cased entirely in plate, laminated *sollerets*, acutely pointed at the toes, covered the feet, while the body was protected by a long-sleeved hauberk of mail, reaching to about the middle of the thigh, with laminated *épaulières* or shoulder-guards, and *coudières* or elbow-guards. The long sword, with cross-guard, and the short dagger or *misericorde* were now in fashion, and heraldic crests were generally adopted before the close of the century. The first ten years of the 15th century were a period of transition, and from about 1410 the armour became a complete panoply of plate. The period of complete armour of plate which commenced about 1410 extended to the beginning of the 17th century. At the commencement of this period, or towards the middle of the first quarter of the 15th century, the body armour consisted of breast and back-plates of one piece, the *roundles* at the shoulders were replaced by plates resembling small shields fixed in front of the shoulder-joints, and a fan-like arrangement of plates protected the elbows. Below the waist the body was protected by the *taces*, a series of narrow, overlapping plates attached to a lining of leather. The crested helm, sometimes with the addition of a collar, was still in use in battle and tournament. The bassinet was more globular in form, and connected by a gorget with the suit of plate. By the middle of the century the same system of re-inforcing, or adding secondary protections to cover the weaker points, which gradually changed the mail into a complete panoply of plate, had effected considerable changes on the character of the plate-suits, until the corresponding defences of the right and left sides of the figure became totally unlike each other. The *tabard*, a short surcoat with short sleeves, emblazoned with the arms of the wearer, now commonly appears over the armour. By the end of this century the defensive system of plate-armour had reached its highest development. At the commencement of the 16th century, a species of armour of less rigid and cumbrous description often formed of small plates of metal quilted within garments of linen or other tissues, had come into fashion, skirts of mail also came again into use, while the armour generally became more massive and more richly decorated. Pointed or rounds *sollerets* gave place to *sabatons* cut off square at the toes, and plumes were generally attached to the helms. The *salade* and the *morion*, light open head-pieces, gave place to the closed helmet, with visor and beevor; the recurved finger-guard, with the long straight sword, and all varieties of the sabre, came into use; and two-handed swords and sword breakers (curious implements, with notches and springs for catching the blade of an antagonist's sword) were also used. As the century advances the decadence of armour begins to be evidenced by its assimilation to the forms of dress and prevailing fashions of the time. Mere surface ornamentation is more and more regarded; fluted, laminated, and puffed suits are fashionable and the gradual disuse of armour is foreshadowed in the increasing use of fire-arms, against which it afforded no sufficient protection. After the close of the 16th century it continued to be worn as much for display as for real service. Cuirasses began to be superseded by buff coats and jerkins, but demi-suits of plate were worn by cuirassiers far on in the 17th century. The variations of tilting arms and armour, and of horse

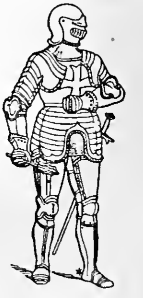

FIG. 6.—Suit of Plate, early in 16th century

armour, are too numerous to be specified in a short notice. For these and other details the works of Grose, Meyrick, Skelton, Stothard, and Hewitt may be consulted by those who wish to study them fully, while the copiously-illustrated works of Demmin and Lacombe, recently translated by Mr Black of the South Kensington Museum and Charles Boutell, are excellent popular manuals of the general subject.

Artillery.—The adoption of gunpowder as an agent in warfare gradually revolutionised the whole system of military tactics, and was not only the ultimate cause of the total disuse of defensive armour, but rendered obsolete the whole of the projectile machines and weapons of the Middle Ages. Bows and shields were the first to give way before it, as they were the oldest forms of weapons of offence and defence. Shields are not represented on English effigies after the last quarter of the 14th century, though the round Highland target survived with the broadsword till 1745. The long-bow, which became such an important weapon in the 13th and 14th centuries, was usually of yew, about five feet in length, and a practised archer would send an arrow of a yard long through his mark at a distance of 240 yards. The cross-bow, which is first mentioned by the Princess Anna Comnena, appears in an Anglo-Saxon manuscript of the 11th century. Its use against Christians was prohibited by the Lateran Council in 1139, although it was allowed against the infidels. The long-bow continued in use in England till the end of Queen Elizabeth's reign, and the cross-bow was only disused in the French army in the 17th century, so slow was the process of transition from one system to another, even after the superiority of gunpowder had been long well known. Gunpowder had been in use for centuries, however, before it was applied to projectiles. The Chinese used it in their fireworks at a very early date, and it is believed to have been introduced into Europe by the intercourse of the Arabs with the natives of the far East. The earliest receipt for its composition with which we are acquainted occurs in the *Liber Ignium ad comburendos hostes* of Marcus Græcus (846 A.D.), where it is described as including six parts of saltpetre, two of sulphur, and two of charcoal. A similar receipt occurs in the *De Mirabilibus Mundi* of Albertus Magnus, bishop of Ratisbon, 1280 A.D. Until about the beginning of the 14th century, however, it had not been applied in warfare to the purpose of throwing projectiles, and was probably regarded merely as an explosive mixture, like the "Greek fire" and similar preparations, employed to spread terror and conflagration. Large cannon were used on the Continent in siege operations, however, as early as the beginning of the 14th century. Cannon are first mentioned in England in 1338; Froissart alludes to them in 1340, and it is certain that they were used by the English at the siege of Cambray in 1339. At the same time experiments were being made at Tournay with long, pointed projectiles, and the duke of Brunswick had substituted leaden bullets for those of stone which were then in common use in his artillery. Carronades were used on board the French ships at the battle of Rhodes in 1372, and bronze cannon were cast at Augsburg in 1378. Towards the end of the 14th century there were *bombardes* in existence, capable of throwing balls of stone of 200 lbs. in weight. All early cannon were breech-loaders, and at first they were built of bar of wrought-iron hooped together. The well-known Scottish *bombarde*, Mons Meg, which was used at the sieges of Dumbarton and Norham in 1489 and 1497 is made in this way. So early as the beginning of the 15th century the prototypes of the modern *mitrailleuse* were invented. In Germany they were subsequently styled "death-organs," and Weigel mentions one which had as many as thirty-three pipes. In the 15th century cannon of a lighter kind than those used in siege operations began to be employed in the field, carriages with trails were introduced, trunnions were added to the guns, and iron balls became common. With the improvement in the manufacture of the gunpowder it was found that the increased velocity of the projectile made up for the diminution of its weight; and throughout the 16th century, the course of improvement was chiefly directed to the lightening of the enormous weights of the guns and projectiles, so as to secure facility of transport. So much progress had been made in this direction by the middle of the century, that, in 1556, the Emperor Ferdinand was able to march against the Turks with 54 heavy and 127 light pieces of artillery. At this period the French artillery were restricted by Henry II. to the following sizes:—Cannon throwing a projectile of about 34 ℔; culverins of three sizes, throwing projectiles of 15 ℔, 7½ ℔, and 2 ℔ respectively; and the falcon and the falconet, the former of which threw a projectile of about 1 ℔, and the latter of less than half a pound. In the second half of the 16th century mortars began to be used in Germany, and howitzers, or pieces for discharging hollow projectiles in a horizontal direction, came into use in England about the same period. At first the mortars were discharged by double firing, the artilleryman lighting the fuse of the shell with one hand and the priming of the mortar with the other. It was not until 1634 that the mortar was introduced into the French army; and towards the close of the 17th century the method of igniting the fuse of the shell by the discharge of the piece itself became general, and greatly simplified the use of the arm. Though Benjamin Robins (who died in 1742) is sometimes spoken of as the inventor of the greatest improvement of modern times,—the application of the system of rifling to artillery,—he was merely the first who treated the subject scientifically. There are rifled cannon of the 16th century in the museum of the Hague. One in the arsenal at Berlin, dated 1661, is rifled with 16 grooves, and one at Nuremberg, of 1694, has 8 grooves. But it was not till after the time of Benjamin Robins that, by the application of an armature of softer metal to the iron projectiles of the rifled guns, the difficulty was surmounted of enabling them at the moment of explosion to fit themselves tightly into the grooves of the rifling. The improvements of Paixhans in 1822, and of Armstrong in England and Krupp in Prussia, have brought the manufacture of these monster pieces of ordnance to the highest pitch of perfection. Krupp's cannon are made of cast-steel, and one of these, a breech-loader, exhibited in 1867, weighed close on fifty tons, and its shot, also of cast-steel, were somewhat over half a ton in weight. The most recent, and perhaps the most important improvement in the working of heavy ordnance is that of Captain Moncreiff, by which the recoil of the gun itself is utilised, so as to withdraw it under the parapet, and by means of a counterpoise to elevate it again, after it has been reloaded and laid by means of reflecting sight. These operations are thus conducted without exposing a man, and the gun itself is only exposed at the moment of delivering its fire.

Hand Fire-arms.—Hand-cannons appear almost simultaneously with the larger *bombardes*. They were made by the Flemings in the early part of the 14th century, and before the end of the century considerable bodies of troops were in existence armed with portable *culverins*. At the battle of Morat (1476) the Swiss army is said to have been provided with 6000 of these hand fire-arms. In England the yeomen of the guard were armed with them in 1485. At first these portable fire-arms were served by two men, but a smaller kind termed *petronels* were used by the cavalry. The long-barrelled *harquebus*, the prototype of the modern firelock, having the touch-hole on the right side of the barrel, with a pan for the priming, a trigger, and a pair of movable nippers, called *serpentine*, for holding the match, was invented in Spain in the time of Francis I. (1515–1547). The *muschite* (so named from the sparrow-hawk, like the *falcon* or small cannon) which was larger, heavier, and more powerful than the *harquebus*, came into use shortly afterwards, and was well known in England before the close of the 16th century. On account of its weight it was provided with a long rest, forked in the upper part and furnished with a spike to stick in the ground. The *musket* and *harquebus* when first employed by the French armies were contemptuously spoken of by contemporary writers, by whom they were considered inferior to arblasts and cross-bows. The wheel-lock, which was invented at Nuremberg in 1515, was but sparingly applied to the harquebus and musket on account of the costliness of its mechanism and the uncertainty of its action. The same objection applied to the *snaphaunces*, the precursors of the first flint locks, and even to the flint locks themselves, which were invented in France about 1640, and it was not till the beginning of the 18th century that the flint-lock musket finally superseded the old match-lock. In 1807 a Scottish clergyman, Alexander Forsyth, took out a patent for a percussion gun, though it was not till 1820 that it begau to come into general use. The system of firing the charge by a fulminate was followed by the invention of the needle-gun, the first model of which was constructed in 1827 by Jean Nicolas Dreyse, a native of Erfurt. Improvements in the mode of adapting the bullet to the rifled grooves successively led to the perfected system of the Minie rifle, by which the explosion of the charge expands the cup-shaped end of the conical bullet, and drives it into all the grooves, a process which was previously effected by hammering with the ramrod. The needle-gun was first made breech-loading in 1836, and since that time the improvements effected have been mainly directed to the combination of length of range with accuracy of aim and rapidity of fire. According to an official report, the results of the trial at Spandau of the needle-gun used by the different nations of Europe was as follows:—the Prussian, 12 shots per minute; the Chassepôt, 11; the Snider (England) 10; the Peabody (Switzerland), 13; the Werndl (Austria), 12; the Remington (Denmark), 14. Neither breech-loaders nor revolvers, however, are inventions of modern date. Both were known in Germany as early as the close of the 15th century. There are in the Musée d'Artillerie at Paris wheel-lock *harquebuses* of the 16th century which are breech-loaders; and there is, in the Tower armoury, a revolver with the old match-lock, the date of which is about 1550. A German harquebus of the 16th century, in the museum of Sigmaringen, is a revolver of seven barrels. Nor is rifling a new thing in fire-arms, for there was a rifled variety of the old harquebus of the 15th century, in whi h the balls were driven home by a mallet, and a patent was taken out in England for rifling in 1635. All these systems were thus known at an early period in the history of fire-arms, but it is only the perfecting of their mechanism and rifling, the improvements in the gunpowder and the cartridge, and above all the adoption of the system of firing by a fulminate, that have enabled them to be used with the precision, length of range, and rapidity of fire, that now form such striking features in the warfare of modern times. It remains only to notice the bayonet, the invention of which, about 1650, has been claimed for Puséygur, a native of Bayonne. The bayonet in its simple plug form, inserted into the mouth of the barrel, was adopted in France and England about 1675. In 1689 it was attached by two rings to the barrel by General Mackay, and the socketed bayonet was introduced by Vauban into the French army in 1703. In these days of precision of aim with long-range projectiles the bayonet, once the most decisive of modern weapons, has become of secondary importance.

Collections.—The formation of historical collections of arms and armour dates no further back than the commencement of the 16th century. The earliest is that made by Louis XII. at Amboise in 1502. The magnificent collection at Dresden was begun about 1553. The Ambras collection, now at Vienna, of which a series of illustrative photographs has been published by the Baron von Sacken, was commenced in 1570. There is also a splendid collection in the Imperial Arsenal at Vienna, which has been described, with illustrations, by Captain Leitner. The Musée d'Artillerie at Paris, catalogued by M. l' Haridon, is one of the richest and best organised collections in Europe. In the Armeria at Turin there is a fine collection, of which a catalogue has been published by Count Seyssel. The collection at Sigmaringen is catalogued and illustrated by Dr Lehner, and that of Munich by M. de Hefner-Alteneck. Of the remarkable collections at Tzarskoe Selo, St Petersburg, and at Madrid, there are no detailed descriptions. The collection in the Tower of London, which was classified by Dr Meyrick, and catalogued by Mr John Hewitt, contains about 6000 examples, from the commencement of the Middle Ages downwards. The most remarkable private collection ever formed in this or any other country was that of Llewelyn Meyrick at Goodrich Court. It is to be regretted that the opportunity of acquiring this collection in its integrity was missed by the Government. It may be noticed as an indication of popular interest in the subject, that a Museum of Arms, including specimens from the earliest period, has been recently established in Birmingham, containing, in addition to a series of fire-arms granted by the Government, a fine and extensive collection made in Italy by the Cavaliere Callandra, of which the guardians of the Birmingham Proof House have become the purchasers. If we except the National Museum of the Antiquaries at Edinburgh, which contains a fine series of stone and bronze weapons, and a few typical examples of the arms of later times, there is no public collection of arms and armour in Scotland. (J. AN.)

ARMSTRONG, JOHN, a physician, litterateur, and poet, the friend of Thomson, Mallet, and Wilkes, was born about 1709 at Castletown, Roxburghshire, where his father was parish minister. He graduated M.D. at Edinburgh university, and soon afterwards settled in London, where, however, his professional success was small. In all probability he paid more attention to literature than to medicine. He was, in 1746, appointed one of the physicians to the military hospital behind Buckingham House; and, in 1760, physician to the army in Germany, an appointment which he held till the peace of 1763. His latter years seem to have been embittered by disappointments, as is evinced by the tone of his writings, in which he particularly directs his sarcasms against his medical brethren and the reviewers. He died in 1779. Armstrong's first publication, an anonymous one, entitled *An Essay for Abridging the Study of Physic* (1735), was a satire on the ignorance of the apothecaries and medical men of his day. This was followed two years after by the *Economy of Love*, a poem the indecency of which damaged his professional practice. In 1744 appeared his *Art of Preserving Health*, a very successful didactic poem, and the one production on which his literary reputation rests. Along with this poem were published, in 1770, a number of shorter poetical pieces, under the title of *Miscellanies*, in which he displays considerable humour and powers of observation.

ARMY

ARMY, "a collection of armed men obliged to obey one man" (Johnson); "a collection of troops of all arms formed into brigades and divisions, placed under the orders of one commander, with a general and special staff and administrative departments; provided with all necessary war materiel, and destined to act offensively and defensively against the enemy" (Block, *Dictionnaire de l'Economie Politique*). Neither definition is quite satisfactory. The first is too comprehensive; the second excludes the forces of all but highly-civilised nations. The essential characteristics of an *army*, by which it is distinguished from other assemblages of armed men, are its *national* character—that is, its representing more or less the will and the power of the nation or its rulers—and its *organisation*. The degree of the latter must depend on the age and the state of civilisation; the armies of former days we should now call mobs. The art of war has kept pace with the arts of peace, and there is as much difference between the "armies" of the present and of the past as between an elaborate modern machine and an early stone implement. But armies of some kind have existed since the earliest periods of man's history. At no time has industrial accumulation, with its results, progress and civilisation, been possible unless accompanied by the will and power to defend it. No nation has made its mark in history that has not at some period of its existence been pre-eminently distinguished for martial spirit and proficiency in arms; or been allowed to throw its full energies into the pursuits of peace till it had proved what it was able and willing to do and endure in war. In studying the progress of military art we dwell in succession on the proudest days of all the great nations of the earth, and learn that when this art was neglected the fall of the nation was seldom far distant.

The art of war divides itself into two distinct branches—the first relating to the military institutions of nations, the manner in which armies are raised, their composition, characteristics, organisation, and government; the second to their employment in war. The first, commonly known as the administration or organisation of armies, is that of which this article treats. A modern army is a vast and complicated machine, so constructed that the whole aggregate force of its numerous parts may be exerted in any direction and on any point required. It is our province to describe this machine in a state of rest, explaining the construction, purpose, and combination of its several parts, but leaving its action to be treated of elsewhere (see WAR).

Early armies.

In the earliest stage of civilisation the army is identical with the tribe or nation. Every man is a warrior; even women and children accompany the expeditions, prepare and carry food, and bear such share as they are fitted for. In more settled communities the able-bodied men only take the field, while the women, the children, and the aged remain at home to watch the herds and till the fields. Production is still so small that no division of duties among the men is necessary. The armies consist of the whole male population, collected under their chiefs and heads of families, or under warriors who have specially distinguished themselves. Such were some of the earliest armies mentioned in history, and such are still the armies of the savage nations with whom our colonial empire brings us in contact,—well fitted for petty warfare between neighbouring tribes or nations, when the assailants confine themselves to raids for plunder and captives, but not for distant expeditions or prolonged operations. As population and industry increase, a division of labour becomes both possible and necessary. A select portion of the inhabitants are specially devoted to military service, either permanently or for a time, while the remainder give undivided attention to pacific pursuits. Standing armies and permanent organisation are thus introduced, and lead to improvements in administration and progress in the art of war, till finally we attain to the perfection of modern organisation.

Egyptian army.

History points to Egypt as the first country in which a regular military organisation was established, and the warrior class, as such, distinguished from the rest of the population. By its earliest laws the revenues of the state were divided into three equal parts, of which one went to the priests, one to the king, and one to the warriors. Sesostris seems to have been the great military organiser of Egypt. Trained by his father from childhood to war, he early distinguished himself in military expeditions against the Arabians and against Lybia, and mounted the throne with visions of universal conquest. To pave the way for such schemes, he gave Egypt a military organisation, dividing it into thirty-six provinces, and establishing a militia or warrior class, called *Kalasires* and *Harmatopoii*, to each of whom was allotted land sufficient for the maintenance of himself and his family. These formed the nucleus of the vast army, amounting, according to Diodorus Siculus, to 600,000 infantry, 24,000 cavalry, and 27,000 war chariots, with which he undertook the conquest of the world. We read that the command of this army was given to the companions of the king, who, like himself, had been trained to arms under his father, and that a strict discipline was maintained and a military code established which forbade corporal punishment, appealing to the higher instincts of the soldier; but of the details of organisation and administration by which so vast an army was moved and fed we can learn little. With this army, aided by a powerful fleet, Sesostris first subdued Ethiopia, and then extended his conquests eastward as far as the Ganges; thence turning northwards and westwards, he swept over the Punjab, the table-land of Tartary, and the north shores of the Caspian, and descended through Sarmatia and Dacia into Thrace. Finally, he overran Asia Minor, and having conquered the Assyrian empire and seated himself on the throne of Ninus and Semiramis, returned in triumph to Egypt after a nine years' absence, and devoted the rest of his life to the peace and prosperity of his kingdom. Such are the accounts handed down by the ancient historians; and if any faith is to be attached to them, it seems clear that he did actually raise and maintain large armies, and with them carry out prolonged and distant expeditions, extending over several years, without interrupting the industry and progress of his own country—facts which in themselves prove a high degree of national and military organisation.

Persian army.

The martial spirit of Egypt, however, seems to have expired with its first and greatest conqueror, and as a nation it has distinguished itself in the arts of peace rather than those of war: the country became the prey of conquerors and the battle-field of other nations, and the palm of military supremacy passed successively into the hands of the Assyrians, the Babylonians, the Medes, and the Persians. The first two nations present no special features in their military systems; their armies, like those of Egypt, consisted mainly of infantry, horsemen and chariots forming but a small though highly-prized element. But the Persian empire introduces us to a more highly developed military organisation, and a system of standing armies closely resembling those of modern times. Drawn from a hardy and nomadic race, its armies at first consisted mainly of cavalry, and owed much of their success to the consequent ease and rapidity of their movements. Constantly extending their power by fresh conquests, the warlike Persians established themselves as garrisons in the subjected provinces, gladly exchanging their own barren mountain lands for these rich and fertile countries, and for some time remained a distinctly conquering and military race. Their empire attained its highest power under Cyrus and Cambyses; the former, the founder of the great Persian empire, uniting on his head the crowns of Babylon, Media, and Persia, while the latter still further extended the empire by the conquest of Egypt. Cyrus seems to have been the founder of that complete military organisation of which we gather details from Xenophon and other writers. To each province of the empire was allotted a certain number of soldiers as garrison or standing army. These troops, formed originally of native Persians only, were called the king's troops. They comprised two classes: the one devoted exclusively to garrisoning the fortified towns and castles, the other distributed throughout the country. To each province was appointed a military commander, responsible for the number and efficiency of the troops in his district; while the satrap, a civil governor, was answerable for their subsistence and pay. Annual musters of these troops were held either by the king in person or by generals deputed for the purpose, and invested with full powers. This organisation seems to have fully answered its original purpose, that of holding a vast empire acquired by conquest, and promptly repelling inroads or putting down insurrections. But when a great foreign war was contemplated, the standing army was augmented by a levy throughout the empire, and each province and tributary nation furnished its quota of men, horses, and provisions. The extent of the empire made such a levy a matter of time. Thus the preparations for the invasion of Greece by Xerxes took three whole years; and the heterogeneous and unorganised mass of men of all nations so brought together was a source of weakness rather than strength. That the warlike Persians, whose reputation rose so high under Cyrus, who were distinguished for their powers of endurance, and a daring courage which despised stratagem and delighted in single combats, should within a century have failed so disgracefully against the Greeks, has often been matter of wonder. Something, doubtless, was due to the fact that their reputation was won over effeminate races, very different from their later antagonists; something also to the degeneracy induced among themselves by years of success and luxury. But it must also be borne in mind that the vast hosts over which the Greeks gained such easy victories comprised but a very small proportion of the true Persians—of the race which had given Cyrus his conquests. The cavalry alone seems to have retained its national character, and with it something of its high reputation, even to the days of Alexander. Nevertheless, the first contact between the Asiatic and the Greek proved that the crown of military glory had passed to the western nation.

Greek armies. The earliest knowledge we have of the military institutions of the Greeks is derived from the pages of Homer. They are glimpses only that we obtain, but they suffice to distinguish many of their characteristics. Their compact formations and subordination and silence in the ranks are contrasted with the looser formation and noisy attacks of the Trojans. Their armies consisted almost entirely of infantry. The leaders fought either on foot, like the rest, or from chariots; and single combats between the chiefs on the two sides were common, and often served to open the battle. We have sketched for us the traits of a hardy, independent, enterprising race, sometimes cruel and quarrelsome, but gallant, high-spirited, and intelligent, and well fitted to become distinguished as soldiers. How these qualities were developed, till the Greek armies and Greek tactics acquired a renown which has lasted to our day, we learn from the laws of Lycurgus and Solon, and from the ample details handed down by Xenophon, Thucydides, and other historians.

By the laws of Athens every free man was liable to military service. Athens. It was not only his duty but his distinction and privilege. The slave worked, the freeman devoted his time to military exercises and to the gymnasium. At eighteen his name was enrolled on the list of fighting men; for two years his duties were confined to home service, and especially to the guarding of Athens; from his twentieth to his fortieth year he was liable to service wherever the good of the state might require. The collectors of taxes, the singers at some theatres, and a few others, were alone exempted. The only privilege granted to the wealthy was that of serving in the cavalry. The infantry, of which the army was mainly composed, consisted of three classes. First were the heavy troops, "hoplitai," armed with a spear, a dagger, a corslet, and a large oval shield. These formed the phalanx or main line of battle, and were composed entirely of free citizens, natives of Attica. Secondly, the light troops, "psiloi," armed with javelins, but carrying little defensive armour, and no shields. These were destined for skirmishing and covering the movements of the phalanx, and were mostly slaves, who followed their masters, serving among the "hoplitai," to war. Thirdly, there were "gumnetai," or irregular light troops, carrying no defensive armour, but provided with javelins, bows and arrows, and slings, to harass the enemy; these usually consisted of slaves or foreign troops. Besides these there was another class, "peltastai," so called from the light shield or target (*pelta*) which they carried, and intermediate between the "hoplitai" and "psiloi."[1] The cavalry consisted entirely of the wealthier Athenians, and was intelligent and enterprising. Each of the tribes of Athens had its own military commander, chosen from itself, and elected for the year only; and an Athenian army thus obeyed ten chiefs ("strategoi") of equal rank. These commanded by turns for the day, while the ten together formed a council of war to consult and decide in cases of emergency. Practically the inconvenience of such a system was obviated by leaving nine of the ten behind, or by the appointment of a "polemarch," a sort of permanent chief of the staff, who carried great weight in the councils.

The Spartans owed much of their specially soldierly Sparta. qualities to the institutes of Lycurgus, which had for their aim to form a nation of warriors, and develop to the utmost those physical and moral qualities which render men invincible. Discipline, unquestioning obedience, uncomplaining endurance, and contempt of danger, were the principles inculcated on the young Spartan from his earliest years, while his body was strengthened by every exercise and trained to every fatigue. As with the Athenians, military service was the first duty of every citizen of Sparta. The age of enrolment was twenty instead of eighteen; but the service lasted till sixty, and was more severe. In peace as in war, the Spartan lived as if in presence of the enemy. War time was, indeed, his relaxation, for he was then accompanied by slaves, carriages, and beasts of burden, and relieved of every labour or fatigue, to keep him fresh for battle. Cavalry was held in disrepute in Sparta; their infantry was formed

[1] The distinction between the *psiloi* and the *peltastai* is not clear, and it would almost seem that they were the same class of troops, the first name being applied to them when used as light troops, the second when formed in close order and attached to the phalanx.

in five "moras," or regiments, corresponding to the five tribes; later, a sixth, which included a small force of cavalry, was added. The armies were usually commanded by the kings of Sparta; when one only was formed, one king remained at home. The king was accompanied by a body-guard, comprising the winners of the prizes at the athletic games, and had attached to him two polemarchs, or chief staff officers, and three administrative officers, who relieved him of all care of details, leaving him free to devote his mind to the great task of his command.

Greek phalanx. The phalanx, formed of the *hoplitai*, or heavy-armed infantry, drawn up eight deep, was the basis of all Greek tactics.[1] The Spartan and Athenian phalanx differed slightly in interior organisation and subdivision, but the general principles were the same. For marching and manœuvring the ranks stood at open order, that is, 6 feet apart; for attack at close order, or 3 feet apart; and for defence at locked order, or $1\frac{1}{2}$ feet apart. The number of men in each phalanx, and the number of phalanxes into which the battle-array was divided, varied according to circumstances; but from 2000 to 4000 seems to have been the usual strength of a phalanx. The *peltastai* and light troops and the cavalry formed round or in rear of the phalanx; the light troops remaining in front and harassing the enemy till the actual moment of collision, and then falling back to the flanks or rear. In counting the forces engaged in a battle, it was usual to reckon only the *hoplitai*, who answered to the knights and men-at-arms of the Middle Ages; but the *peltastai* and light troops generally equalled, and often considerably exceeded, the former in numbers. The Athenian phalanx was less compact than that of Sparta, but more formidable in its attack, the offensive being best suited to the national character of the former, while the passive courage and endurance of the latter shone especially in the defensive. At Marathon and in subsequent battles the Athenians advanced to the attack at a run, while the advance of the Spartans was always deliberate and slow. The Thebans, under the direction of Epaminondas, modified the phalanx, forming it on a narrower front, with greater depth, and the soldiers standing so close in the ranks that they could not turn. This gave more weight at the point of impact, and the Theban column of attack, fifty deep, crushed the Lacedemonian phalanx, only eight deep, when opposed to it at Leuctra and Mantinæa. Xenophon compares the effect to that of a heavy vessel striking a light one amidships with her bow, and dashing her to pieces by the collision. The Macedonian phalanx was a combination and adaptation of the various earlier Greek forms.

The Greek armies were essentially militia. A few guards and garrisons were maintained, but no standing armies like those of Persia; and the troops by whom such perfection in tactics was attained, and such brilliant victories were won, were only called under arms when occasion required, and returned to their civil life when the danger was over. By constant wars, however, this militia had acquired all the character of a regular army; and the Spartan forces especially differed only in not receiving pay for their services. Beyond their own country the warlike reputation and soldierly qualities of the Greeks made them highly prized as mercenaries, and large numbers adopted that profession. Thus we hear of Greek troops in the pay of the Egyptian kings in the time of Cambyses, and later the garrisons of the Persian towns in Asia Minor were mainly furnished by them; while Xenophon and the ten thousand Greeks who engaged under Cyrus the Younger did more to spread the fame of the arms of Greece than even the great victories of Marathon and Platæa, and, by exposing the weakness of the Persian empire, paved the way for the future conquests of Alexander.

Macedonian army. Macedon, inhabited by rude but hardy shepherds and hunters, and far behind its southern neighbours in civilisation, had made no mark in history till Philip ascended its throne. But this monarch, who combined the highest military qualities with a far-seeing shrewdness which was fettered by no strict principles of honour, had no sooner established himself than he devoted all his energies to raising the military power of his country and extending his authority. The experience of his wars with the Athenians and other nations of Greece taught him that he could only overcome them by a discipline and training superior to their own, and he early saw that such was not to be given to a mere militia force. He set himself, therefore, to form a standing army, to which he gave an organisation, copied, but improved, from that of his adversaries. By force of arms, by treachery, or by policy, he increased his power and influence till it embraced all Greece; and he was about to make war on Persia at the head of her united armies when his death put an end to his ambitious projects. But his son Alexander had all his father's military genius and ambition, and at the same time inherited the instrument he required in the highly-trained army so carefully prepared. Within a year he had chastised the Thracians in the north, stamped out the Greek revolt by the storming and destruction of Thebes, and received at Corinth from the representatives of the southern states the chief command over their united forces; and in the following year crossed the Hellespont at the head of an army of 35,000 men, and commenced that career of conquest which was not to cease till he had carried his victorious arms over India, and founded the largest empire the world had yet known. The army with which these astonishing campaigns were won was composed of native-born Macedonians, of their allies, and of mercenaries. The infantry was divided into heavy and light armed, the *peltastai* now forming a most important part of the force, besides auxiliaries or irregular troops. None but native Greeks were admitted into the phalanx or the cavalry. The cavalry, which was more numerous than that of the Spartans or Athenians, was also divided into heavy and light; the former carrying horse armour as well as body armour. The actual force with which Alexander crossed the Granicus, the frontier line, was 30,000 infantry and 4500 cavalry, of whom about 12,000 were Macedonians, 5000 foreign mercenaries, and the remainder Greeks and allies. Special attention was paid to recruiting, generals being left behind to attend to it, and numerous reinforcements were sent to Alexander during his expeditions, so that at the battle of Arbela his army amounted to at least 60,000 men. The tactical organisation of his army was adopted from the Greeks. The Macedonian grand phalanx, as finally formed by Alexander, numbered 16,384 heavy-armed infantry: it was formed 16 deep, each file of 16 men forming a *lochos* under a *lochagos*, who led the file, and thus became the front rank man. These files were variously grouped. Thus two files formed a *dilochie*, four a *tetrarchie*, two tetrarchies a *taxiarchie*, under a *taxiarch* or *centurion*, &c.; and 32 taxiarchies, or 256 files, formed a *simple phalanx* of 4096 men. Four of these, with a due proportion of peltastai, light troops, and cavalry, formed the *grand phalanx*. The depth of 16 was chosen as giving greater solidity than the Spartan phalanx, while admitting of more subdivision. To form a solid column the phalanx was doubled, giving a depth of 32; to extend its front, its depth could be reduced to one-half, still offering a firm line. The principal weapon was the *sarissa* or pike, 24 feet long, of which 18 feet extended beyond the grasp. Thus the pike heads of six ranks

[1] The various formations cannot here be described in detail.

projected beyond the front, and formed that bristling mass of spears which gave the phalanx its formidable appearance. The proportion of peltastai, cavalry, and irregular troops attached to the grand phalanx varied slightly, but as a rule the total about equalled that of the phalanx. Of these, the peltastai would form one-half, the cavalry and irregular troops about a quarter each. Thus the total strength of a grand phalanx and its auxiliaries amounted to about 32,000 men, and Alexander's army at Arbela was formed of two such. The Macedonian phalanx was the crowning point of Greek military organisation, and therefore has been described at some length; but a still greater military power was already rising in the West, before whose legions the phalanx itself collapsed, and to this it is now time to turn.

Roman army.

The early or legendary period of Roman history is enveloped in a darkness which hides the rise and first development of those institutions which ultimately gave to Rome the empire of the world. Her earliest military organisation is attributed to Romulus, who grouped the great families or clans ("gentes") in three tribes; each required to furnish 1000 foot soldiers and 100 cavalry, and in the force so raised is traced the origin of the Roman legion. But it is to Servius Tullius that the legend assigns the great classification, lasting to the time of the Cæsars, according to which the burdens and duties of military service were determined. The whole population was numbered and divided, according to wealth, into six classes; the class determining the amount of war-tribute to be paid by the citizen, his position in the army, and the armour he had to provide. The legionary infantry, *Triarii, Principes, Hastati*,[1] were usually drawn from the first four classes; the light troops, "*Velites*," from the fifth; while the sixth and poorest class was exempted from all military service and from the tribute. For voting purposes and for enrolment these classes were subdivided into centuries; and a certain number of special centuries of "equites" were formed from the patricians and most wealthy citizens, who were required to provide horses as well as armour, and formed the cavalry of the legion. Every five years a fresh census was held, and the classification according to property revised. Liability to service commenced at the age of seventeen, and lasted until forty-six; and no Roman citizen could aspire to any office until he had served ten years in the infantry or five in the cavalry. The manner of raising the annual levy of troops is minutely described by Polybius. Immediately after the election of the consuls, twenty-four military tribunes were chosen from among the citizens of longest and most distinguished service. The consuls having published the day on which all persons liable to service were to assemble at the capital, the military tribunes were apportioned to the several legions. The magistrates then proceeded to choose from the different tribes, in order determined by lot, those most fit for military service, and sent them, in groups corresponding to the number of legions, before the military tribunes, who selected in turn for their several legions till the required numbers were raised. The conscripts then took the military oath, *sacramentum*, and were dismissed until the appointed muster-day, when the legion was formed and organised. The youngest and poorest were made *Velites*, the next in age *Hastati*, the most powerful were selected for the *Principes*, and the oldest or richest reserved for the *Triarii*. The legion was commonly composed of 600 Triarii, 1200 Principes, 1200 Hastati, and 1200 Velites, with 300 cavalry,—making a total strength of 4500; the number of Velites, however, often varied considerably. When the classification was completed, the three classes of Triarii, Principes, and Hastati were divided into ten *manipuli* or companies each, and the cavalry into ten *turmæ* or troops; while the Velites were distributed among the thirty manipuli. A first and second centurion was then chosen and appointed to each manipulus; and these again chose each two "ensigns" from their manipuli. The centurions ranked among themselves according to the class to which they belonged; thus a centurion of Triarii ranked above one of Principes or Hastati, and the first centurion of each class commanded the whole of his class or one of the lines of battle of the legion. Originally Roman citizens only, belonging to the five upper classes, were admitted in the army, and the soldier equipped himself at his own cost, and received no pay. Afterwards, the socii or allies of Rome were included in her armies, and in the time of Polybius a consular army consisted usually of two legions, or 9000 Roman soldiers and about the same number of allies or socii. But under the pressure of the great Punic wars the consular armies were often doubled: at Cannæ two double consular armies, or nearly 80,000 men, were brought together; and at one period of the second Punic war as many as 23 legions were raised. The system of payment, too, dating from the prolonged siege of Veii, removed the reasons for exempting the poor from military service, and they were included in the levies, though usually detailed to the navy as an inferior service. Finally, when civil wars had shaken the old institutions, and everything was sacrificed to faction and party spirit, even slaves and criminals were enrolled, and the whole character of the army was changed. Other causes also tended to the same result. The system of raising the consular armies annually, and disbanding them at the conclusion of each campaign, required to be modified when distant wars were undertaken: legions were kept permanently under arms, and recruited annually by levies sent from Rome; ambitious generals found excuses for not disbanding the armies to which they owed their power, and by degrees a standing army was established; and these changes in the character of the army were accompanied by corresponding changes in its organisation and tactics. The distinction between the three ranks became gradually effaced, and the three corresponding manipuli were merged in the *cohort*. The legion was no longer divided into three lines and thirty manipuli, but into ten cohorts, and its force was raised from 4000 to 6000 men. The manner of fighting, too, was gradually changed, and the Roman soldier learned to trust less to his sword and heavy *pilum*, only useful at close quarters, and more to javelins and warlike instruments.

The turning-point in Roman military art is commonly fixed about the time of Marius, to whom the change in the organisation, as well as in the composition, of the Roman armies is attributed. But the evil effects did not make themselves felt immediately, and the legions, whose actions under Cæsar shed the brightest lustre on the Roman arms, were organised on the new system. So long as discipline and the old military spirit remained, the Roman armies retained their superiority, whatever their tactics. This spirit was too deeply implanted to die out soon; and whenever men arose worthy to command them, the Roman soldiery regained its reputation. But under a succession of weak and profligate emperors all discipline was lost: the legions, degenerated into a feeble militia, sold the empire which they were incapable of defending, and ultimately fell an easy prey to the rude and daring barbarians of the North.

The Roman armies owed their long and remarkable

[1] The "Hastati," so called from the "hasta," or spear, were comparatively lightly armed, and usually formed the first rank of the line of battle; the "Principes," heavily armed, formed the second rank; and the "Triarii," armed with shields, body armour, and short heavy spear ("pilum"), formed a third rank or reserve.

ascendency to three principal causes: discipline; care in the selection, training, and exercise of the soldiers; and readiness in adopting improvements, whether from friends or foes. In the first the Romans surpassed all other nations. The second especially attracted the attention of contemporary students of their military institutions; Hirtius, Vegetius, Josephus, all speak of the constant exercises by which, in peace as in war, the Roman soldier was trained and inured to war. "If," says Josephus, "we consider what a study the Romans made of military art, we must confess that the empire to which they have attained is not a gift of fortune, but a reward of virtue. They did not wait for war to handle their arms; nor, slumbering in the bosom of peace, move themselves only when awakened by necessity: as if their weapons were born with them, as if they formed part of their members, they allowed no truce to exercises; and these military games are real apprenticeship to combat. Each soldier tests his strength and courage every day; thus battles are neither new nor difficult to them; accustomed to keep their places, disorder never arises, fear never troubles their minds, fatigue never exhausts their bodies. They are certain to conquer, because they are certain to find enemies unequal to them; and one may say, without fear of mistake, that their exercises are battles without bloodshed, and their battles bloody exercises." Josephus said truly, they would never meet their equals. When they fell, it was not because their adversaries were superior, but because they themselves were no longer what they had been.

Early military institutions of Europe.

Hitherto war had been a progressive art. Each great military power succumbed in its turn to an organisation and a science superior to its own. But with the fall of Rome we seem to begin afresh. The nations by whom the overthrow of this great empire was effected were in the condition from which the Latins had emerged ten centuries before; and more than ten centuries elapsed before the lost ground was regained, and such highly-trained armies again appeared.

The early institutions of the Frank and German races, the new masters of Europe, were those of a free, proud, warlike people. The right to bear arms was the privilege of the freeman, the mark of his status in the community. No man could assume it till publicly pronounced worthy, and solemnly invested before the assembly of the people. From that time he was never separated from his arms. The same word (*wehr*) denoted a weapon and a freeman; even his plot of land (*were*) was named after that by which alone he held it, and his social existence ceased when no longer able to carry arms and mount his horse. Similarly, nation and army were convertible terms; the Longobards continued to call themselves an army (*Heer*) long after their settlement in Italy. Their organisation was rude and simple. The family was the basis of the social fabric; kindred families formed clans, and these again confederations (*Markgenossenschaft*), to which admission was only obtained by common consent. Finally, the kindred tribes or communities occupying a certain district (*gau*) formed a higher organisation (*gaugemeinde*), which usually included the whole of a particular race or stock, and had well-defined natural boundaries. For political and military purposes the gau or province was subdivided into "circles" (*Kreis*) and "hundreds," names which have continued to this day; the latter calculated to include as many households as would suffice to place a hundred warriors in the field. Kings and commanders were elected and were entrusted with absolute power in war time, but in peace every freeman claimed perfect liberty; all great questions were determined by the people in public assembly, and all conquests were the property of the community, to be shared equally among them. It is hard to imagine a greater contrast than that between the perfect freedom and equality of the early German institutions, and the tyranny and unequal rights of the feudal system which succeeded it.

Rise of the feudal system.

But we can trace the gradual transition. From early days the most adventurous youths attached themselves to the hero of the nation or tribe, to be instructed by him in peace and led to victory in war. Thus each great warrior collected round him a band of personal followers—retainers, whom he equipped with horses and armour, and rewarded with a share of the booty, and who in return followed him in all expeditions, and obeyed no law but his word. When conquests were effected by such bands, the land was the property of the chief, and was distributed by him as a reward to his followers. Gradually kings and chieftains increased their retinues, extending protection to those who obeyed them, and enriching them by grants of lands acquired by conquest or seizure. These grants soon ceased to be free gifts, rewards for past service, but were held to entail future service also; and the chiefs assumed the right to revoke them. As the power of the nobles and the number of their retainers increased, so did the number and power of the independent freemen decrease; a prey to oppression and exactions of all sorts, they attached themselves in self-defence to some neighbouring lord, surrendering their lands, and consenting to hold them of him as vassals. Finally, the lords increased their pretensions, assuming the titles of "suzerains" or "seigneurs," claiming absolute authority over the persons and property of their vassals, and requiring an oath of fealty from them; and the feudal system, with all its grinding tyranny, was established. Nations were broken up into small seignioralties, whose lords, at constant war with each other, only united to resist any interference with their privileges; and if occasionally a powerful ruler like Charlemagne succeeded for a time in establishing a real government, it was only personal, and collapsed as soon as the strong hand was removed. No great national undertakings, no great progress in the arts of peace or war, were possible under such conditions; and it was not till feudalism was nearly extinct that these arts emerged from the darkness of the Middle Ages.

The early Frank and German armies comprised the whole manhood of the nations, rudely organised by "hundreds," or by tribes and families. Some knowledge of tactics had been gained from their adversaries the Romans, and from deserters and escaped slaves in their ranks; but they usually adhered to their own national formation, the wedge shaped column of attack. The principal arm was infantry, divided into "heavy" and "light;" the light infantry being originally the *élite*, and trained to act with the cavalry, but afterwards degenerating into mere attendants of the latter. The transition from the national to the feudal system is seen in the armies of Charles Martel. These consisted in part of his personal followers, partly of mercenaries, and partly of national levies. At Tours the latter still formed the great bulk of the force, and fought, as of old, in heavy masses and with little tactical organisation. Under Charlemagne armies became more feudal, the chiefs and their retainers forming a larger proportion, the national levies a much smaller one; and the frequent levies ordered in his reign did much to extinguish the class of freemen, driving them to seek protection as vassals of the great nobles. The true feudal armies were formed entirely of the knights, men-at-arms, and vassals, who obeyed the summons of their suzerain, either at the call of the king, or for his own private wars, and whose service lasted variously for twenty or forty days or three months, at the end of which the army disbanded and returned home.

The change in the constitution of armies was accompanied by changes in their armament. As the equality of the old freemen gave place to the classification of the people into lords, gentlemen, and serfs, corresponding distinctions in arms and equipment followed; the horseman became the representative of the upper classes, the foot soldier of the serfs and peasants. The feudal system could only be maintained by the superior fighting power of the ruling class. All that money and art could do was therefore lavished on the equipment of the lord and his immediate retainers, while the peasant remained ill-armed and comparatively defenceless. The strength of armies was measured by the number of men-at-arms. Efforts to arm and train the mass of the people commonly originated with the kings, in their desire to form a more national force than the semi-independent feudal levies, and received small encouragement from the nobles. When they succeeded it was a sign of weakness in the feudal chiefs, and of a more popular government. In no country were the lower orders so warlike and used to arms as in England; and historians have shown how essentially popular was the rule even of our most absolute monarchs.

Two characteristics of feudalism were especially adverse to progress in military art: the undue preponderance given to one arm, numerically weak; and the impossibility of unity of action or combined organisation among so many independent and rival authorities. Among the causes tending to bring about a better military system must be reckoned the *Crusades*, those marvellous efforts of fanaticism that still excite a wonder and admiration mixed with pity. It is true they left no mark at all proportionate to the vastness of the efforts. The armies of the Crusaders, as they took the field, were mere tumultuary masses, as destitute of order and discipline as their leaders were ignorant of military science. But for the first time large bodies were kept continuously under arms, and some sort of organisation necessarily developed itself. The knights and leaders becoming conscious of their own numerical weakness, bestowed more care on the arms and discipline of their men, and learnt their value; and the first true infantry of the feudal times dates from the Crusades. An event of very different character, but not less exercising a most important influence, was the grant of the franchise to cities and towns, resorted to by Louis VI. of France in 1135 to establish a counterpoise to the power of the barons, and afterwards adopted in Germany and England. These enfranchised cities raised their own levies (*milice des communes*), and thus furnished the king with a military force independent of and antagonistic to the feudatories, and consisting mainly of an infantry superior in quality to the feudal vassals. Another cause was the ever-increasing employment of mercenaries, due partly to the growing wealth and luxury which made personal service irksome, partly to the proved unfitness of feudal armies for continuous operations. Lastly came the invention of gunpowder, which, though it exercised no immediate effect on tactics, and had little to do with the overthrow of feudalism, ultimately revolutionised the whole art of war.

Fall of feudalism. Rise of standing armies.

The fall of feudalism as a military system, though gradual, as all such changes are, may be said to have been accomplished in the middle of the 15th century. Two events occurring about that time gave it its death-blow—the defeat of the Burgundian chivalry by Swiss infantry in the three successive battles of Granson, Morat, and Nancy; and the establishment of "*compagnies d'ordonnance*" by Charles VII. of France. The first destroyed for ever the overwhelming prestige attached to the mailed horsemen, and restored infantry to the place which it had held in ancient armies, and has never lost since; from the second dates the origin of *standing armies* in Europe. Charles VI. had already sought to substitute a permanent national force for the foreign mercenaries, who were as great a curse to their employers as to their enemies; but the attempt was interrupted by his insanity, followed immediately by internal discord and disastrous wars with England. It was not till sixty years later that Charles VII., having firmly established his power by a series of successes over the English, carried out his father's idea; and (in 1445) organised fifteen "*compagnies d'ordonnance*," to be maintained in peace as well as in war. Each company consisted of 100 men-at-arms, or "lancers," with their attendants, viz., squire, groom or batman, and three archers—the whole force amounting to 9000 men. Three years later, he organised a corresponding force of infantry, 16,000 strong, named franc-archers. The superiority of a standing army over an assemblage of feudal militia was soon proved, and other states imitated the example of France. A change took place in the military system of Europe; the practice of calling out the feudal contingent ceased, and permanently paid troops, regularly disciplined and organised, were substituted for them. These troops were not always national. At first they were largely composed of the old bands of wandering mercenaries; but the proportion of foreigners decreased as the feudal spirit gave way to a more national one.

The development of the new system may be dated from the beginning of the 16th century. Armies, no longer undisciplined feudal levies, were permanently organised in companies and in regiments. The use of fire-arms became general, though it was long before the pike was entirely supplanted. The distinctive duties and value of cavalry and infantry were recognised, and regular tactics introduced for the different arms, the battalion (originally *battaglia*, battle array) becoming the recognised tactical unit for infantry, as distinguished from the administrative organisation by regiments and companies. "Articles of war" were issued to their several armies by Ferdinand of Spain, Francis I. of France, and Charles V., and a regular discipline thus established. From this time to the outbreak of the great French Revolution but little change took place in the manner of raising armies, though their tactical organisation varied according to the arms in use. Armies were raised mainly by voluntary enlistment, compulsory levies being only resorted to under pressure of war. Usually the king or his commander-in-chief contracted with a nobleman, of repute as a warrior, or of large possessions, to raise a regiment—the nobleman to receive a certain sum down and an annual allowance for its maintenance, and to have the command of it. He in his turn engaged "captains," some of whom brought companies with them, others raised companies under his authority, and others, again, merely commanded the men he himself had raised. Royal officers, "commissaries," were appointed to muster these regiments periodically, and see that the colonels fulfilled their share of the contract; and, on the other hand, to issue the pay and provide for the subsistence of the forces. The regiments were sometimes raised for a fixed time, and disbanded at the expiration of that time or at the close of the war; but as standing armies became general, they were maintained permanently, the command being transferred as occasion required; and, as the terms of the contract were always favourable to the colonel, the command of a regiment was a valuable piece of court patronage. The earliest form of organisation, both in the cavalry and infantry, was the company, originally representing the group of men who followed a knight to battle and fought under his banner, and later the bands of mercenaries who served under a "captain." These companies were afterwards grouped and organised in regiments, but for a long time each company continued to carry its own banner, indicating its real origin. Both companies and regiments varied in strength according

Progress in organisation.

to the habits of the country, and according to the wealth or personal influence of the leaders. In the days when men fought in compact masses, and one man's voice could thus control a large number, 500 and even 600 men was not an uncommon strength for a company; and in some nations the numbers never fell very low. In France, however, the policy initiated by Richelieu, and afterwards adhered to by Mazarin and Louis XIV., of breaking the power of the French nobility, and making them followers and dependants of the king, reacted on the organisation of the army; for it was found desirable to give employment to as many of the young noblemen as possible in the royal armies, and therefore to multiply the companies and commands, and the French companies sometimes fell as low as 30 men. As the undisciplined melée of feudal battles gave way to regular and scientific tactics, the necessity of bodies of constant and uniform strength was felt, and the battalion and squadron were introduced as the *fighting* formations of infantry and cavalry respectively. Originally battalions were dense masses numbering several thousand men, and composed of many regiments. As changes in arms led to the adoption of more extended formations, it became necessary to subdivide into smaller fractions, and battalions were gradually reduced in size till they became mere fractions of a regiment. Finally, when the advantages of uniform and permanent organisation were more fully understood, and large standing armies enabled such improvements to be introduced, regiments also were made of uniform strength, and the battalion became a fixed fraction, usually one-half or one-third of a regiment, but still retained its distinctive character as a tactical unit; while for administrative purposes, recruiting, clothing, payment, &c., the regiment was the unit. Similarly, the company remained the lesser administrative unit,—that is, the captain was answerable for the pay, equipment, and discipline of his company in camp and quarters; but on the parade-ground or battle-field the battalion was divided into a number of equal divisions not necessarily corresponding to the companies. In Frederick the Great's time a Prussian battalion consisted of five (afterwards four) companies, but on parade was divided into eight "zugs" (divisions); and the Prussian company column, now so famous, is merely a return to the old formations adopted when the company acted independently.

Tactical changes.

The tactical changes effected in European armies between the beginning of the 16th and end of the 18th centuries, consequent on alterations in arms, need only be very briefly noticed here. In the earlier wars of the 16th century the musketeers formed but a small proportion of the infantry, and the great bulk consisted of pikemen, whose power lay in weight and mass: deep formations were consequently the rule. The cavalry still fought principally with the lance. In the latter part of the century, during the great war of independence of the Netherlands, improvements in fire-arms led to the proportion of musketeers being increased, and the front of battle proportionately extended to give effect to their fire. Thus Maurice of Nassau usually formed his armies in battalions of 500 men, of 250 pikemen, and 250 musketeers each,—the pikemen ten deep in the centre, the musketeers on the flanks. The cavalry also adopted fire-arms, and were taught to trust more to fire than to the effect of the charge. During the Thirty Years' War (1618–1648) the proportion of musketeers was still further increased. The imperial armies under Tilly and Wallenstein still fought in heavy masses, but Gustavus Adolphus reduced his formations to six ranks. The bayonet, introduced about the middle of the 17th century, gradually superseded the pike, and led to a further reduction of the ranks to four. During the prolonged wars of Louis XIV.'s reign, and under the auspices of the great generals of that age,—Turenne, Condé, Eugene, and Marlborough,—considerable improvements were effected in the tactics and organisation of armies, and the permanent grouping of battalions and regiments into brigades and divisions was first introduced. Still further improvements were made during the Silesian and Seven Years' Wars (1740–63). Many changes ascribed to Frederick the Great are really due to Leopold of Dessau, who, under the first Frederick, formed the army which the second Frederick led to victory. He reduced the ranks of the infantry to three, trained them to manœuvre rapidly and with extraordinary precision, and was the author of the drill-book which has remained the basis of all European systems of drill. But the improvements in cavalry tactics were unquestionably due to Frederick himself, who taught them the true secret of their strength, shock and rapidity, and further developed their power by the introduction of horse artillery, able to move rapidly and accompany the cavalry anywhere.

At the close of Frederick's brilliant career every army in Europe had copied that of Prussia more or less closely. Infantry was organised in regiments of two or three battalions, each battalion 500 or 600 strong—this number being determined by the length of line which it was considered one man could effectively control. Cavalry was organised in regiments of four squadrons, each squadron from 100 to 150 strong. Artillery organisation was still in its infancy, a large part of the guns being attached to regiments, and the heavy guns often horsed and driven by contractors. But Gribeauval was laying the foundation in France of the battery organisation afterwards adopted by all nations. The Prussian army, proud of its brilliant series of successes, equally proud of its manœuvring power and drill, was looked up to by all Europe, and believed itself invincible, but in its pride forgot how much was due to the hand which had guided it. The French army had fallen very low in general estimation, and even the American war, and minor successful expeditions towards the end of the century, did little to raise it. The Austrian army was slow to adopt improvements, but had acquired a reputation for tenacity. England, recently driven out of her American colonies, was hardly acknowledged as a power on land.

French Revolution.

Such was the military condition of Europe when the French Revolution broke like a storm over the Continent, sweeping away old landmarks and old systems, covering the land for years with a flood, which, when it receded, left the whole face of the country changed. When, in 1792, the monarchs of Europe banded to crush the revolution, the military force of France was at a very low ebb. The old Royalist army was disorganised by revolutionary passions and frequent changes, and the constituent assembly had rejected the proposed "compulsory service" as at variance with the liberty of the citizen. But on the proclamation that "the country was in danger," volunteers flocked from all parts to join the armies, and a levy *en masse* was ordered to repel the invaders. Officials vied in proving their zeal by the numbers of recruits they forwarded to the frontiers, and patriotism and terrorism combined to fill the ranks. Within three years nearly 1,200,000 men were thus poured into the army, and sufficed to repel the invaders, and form the armies which, under Hoche, Moreau, and finally under Bonaparte, brought France forth victorious in 1797. But the long and bloody war had exhausted the supply, large as it was, and some new system of recruiting became necessary, for it was evident that voluntary enlistment would no longer suffice. In 1798, therefore, Jourdan brought forward and passed the law establishing *conscription*, the basis of all French military legislation since that date, and more or less of that of other countries also. Every citizen was declared liable to service for five years, and the whole male population, between the ages of twenty and twenty-five, was divided into classes and enrolled by name, to be called out as occasion required. It was the terrible power of the conscription that enabled Napoleon to carry on the gigantic wars which characterised his reign, and after losing in the snows of Russia the largest army ever put in the field, to reappear in a few months with another almost as large. Other nations of necessity followed the example of France, and the conscription became general. Prussia still further developed its power by reducing the period of service in the ranks, and passing her soldiers as soon as sufficiently trained into a reserve, thus gradually training the whole of her population. The "short service and reserve" system, the greatest revolution ever effected in this branch of military art, and characterised by a recent foreign writer on political economy as "the greatest, and in its ulterior consequences probably the most important, of the events of our century," owed its origin to the conditions imposed on Prussia by Napoleon at the treaty of Tilsit. Restricted to an army of 43,000 men, the Prussian statesmen evaded the spirit of the clause by sending the trained soldiers to their homes, to be recalled when needed, and replacing them with recruits. This system, by which every citizen becomes also a trained soldier, and there is no limit to the size of the armies save that of population, was at first only partially adopted by other countries. The prejudice in favour of professional armies — soldiers whose business it was to fight and do nothing else—was too strong, and doubts were felt whether these semi-citizen armies would stand the rough trials of war. But after Sadowa, other nations had no choice but to copy it or resign their military position. It is true the lesson was not learnt at once by all, but 1870 and 1871 enforced what 1866 had already taught; and within the last few years every great Continental power has reorganised its military institutions on the model of Prussia.

If we glance back at the history of military institutions in Europe since the fall of Rome, we find it divides itself into four well-defined periods. In the first or barbarous stage we have vast armies or hordes, formidable from their numbers and the courage of the warlike freemen composing them, but almost without tactics or organisation. In the second or feudal period we have armies nearly as numerous, but whose strength lay entirely in a small body of highly-equipped knights and men-at-arms,—the bulk of the army no longer freemen fighting for their country, but slaves fighting at their lord's command. Little progress has been made in tactics and organisation, and the fighting power of nations is exhausted in constant petty wars. In the third or "standing army" period we have small armies of highly-trained professional soldiers forming a class distinct from the rest of the population, tactics and organisation becoming a science and making vast progress. Lastly, under the conscription we have armies once more national, embracing the whole male population, more numerous than ever, but now trained and organised with all the science and skill of professional soldiers. Some remarks on the general principles involved in this branch of military art will serve as introduction to a more detailed account of existing armies.

The military institutions of a nation are governed by various considerations, the principal of which are geographical position, policy, national character, and wealth. A country like America, which is threatened by no powerful neighbours, can devote its whole energies to peaceful pursuits, and reduce its army to a mere police force. But a European state, surrounded by warlike and powerful nations, may depend for its very existence on its army, and must consequently keep pace with its neighbours, and develop its forces to the utmost that industrial and economical considerations admit of. Political economists class all military expenditure as non-productive. Perhaps it might more fairly be called indirectly productive, as necessary to the maintenance and extension of civilisation, and the protection and development of trade. Further, the value of property increases with increased security, and military expenditure within certain limits thus tends to repay itself. Broadly, however, it may be treated as a tax for insurance, and as so much withdrawn from the productive power of the nation. The object of all military institutions is to develop the highest amount of fighting power,—that is, attain the greatest security with least strain on the industry of the country,—the latter being measured not by the cost of the army as shown by the budget, but by the amount of productive labour withdrawn and disturbance produced. All questions, therefore, have to be considered under two aspects, military and economical—that of efficiency and that of cost.

Mode of raising armies.

The first question that presents itself is the manner of raising armies. There are two methods,—that of voluntary enlistment, and that of compulsory levies or conscription, the former once the universal system, but now retained by England alone; the latter adopted by all other European powers. By voluntary enlistment the burden of military duty is distributed evenly throughout the community, the soldier receiving fair wages for his service, while the citizen bears his share in the form of taxes. Personal liberty is not interfered with, the industry of the country generally is undisturbed, those members only are withdrawn who are likely to contribute least to its wealth, and the army becomes a useful school and refuge for the restless classes of the community. But the supply of recruits is fluctuating and uncertain, they are drawn almost entirely from the lowest class, every desired improvement is hampered by considerations of its effect on recruiting, and the army tends to become a class rather than a national one. Compulsory service gives unlimited command of men, introduces a higher class in the ranks, and raises the tone of the army generally; while military efficiency alone has to be considered in organisation. But it presses much more severely on the country. Military service becomes a tax inflicted by lot, falling with excessive weight on some, while others escape free. "Admit substitutes (or exemption by payment), and the hardship falls exclusively on the poor; insist on personal service, and the loss of time, which to the young man of fortune is nothing, and which to the lowest class of labourer is unimportant, because the pay while serving is as good as he would get elsewhere, becomes a very heavy tax on the skilled industry of the artisan or the professional man, or those who have business habits to acquire."[1] Hence in all countries where personal service is enforced, it is necessarily accompanied with provisions for softening its hardships and reducing its inequality. The time of service is reduced to a minimum, and a special short course is established for men of means and education above the average. Exemptions are permitted on personal or family grounds, and in Prussia these exemptions are carried so far that the ballot is practically done away with; and in some countries money payments are required from all who do not serve. The relative cost of the two systems depends upon the size of the army. So long as the numbers required are small and can be obtained at a fair

[1] Speech of Lord Derby, *Times*, 15th December 1870.

rate of wages, voluntary enlistment is the cheaper of the two; but when the numbers are large, and excessive wages are necessary to stimulate enlistment, compulsory service becomes economical. Such an army as England maintains is actually raised with less cost to the nation by the former system; but armies such as those of the Continental powers are only possible under the latter. So heavily, however, does the conscription press on the life of a nation, that it may safely be asserted that no nation ever did or will accept it, except of necessity.

Terms of service. The next great question is that of the terms of service. No nation can afford to keep constantly under arms the whole force which it may require to put forth in war. In olden times fresh armies were raised on the outbreak of each war. The great step in modern organisation was the maintenance of permanent *cadres* and the formation of trained reserves. Military forces are now divided into "standing armies," comprising those who are actually doing duty as soldiers, and forming in peace time the cadres and the school of instruction of the army; and "reserves," under which name are included all who pursue their industrial callings in peace, but are called to arms in war. Such reserves, however, may be of very different value, from the Prussian "reservist," a trained soldier in the prime of life, to the *garde mobile* or volunteer who has only attended a few drills; and their value is always closely connected with the system and terms of service. There are practically three systems. The first, or *long service* system is now almost obsolete,—it partly lives in England alone. Under this the soldier was engaged for life, or for a long term of years, remained with the colours so long as fit for service, and was then discharged, usually with a pension. It produced a highly-trained army, in which discipline, mutual reliance, *esprit de corps*, constancy under discouragement, and all soldierly qualities, were carried to their highest pitch. The soldier made the regiment his home, and knew no law but the word of his commander. But such an army was necessarily small, being maintained in peace as well as in war, and could form no reserve, as all remained with the colours till they were no longer fit for service. In war, therefore, it had to be increased, and its casualties replaced by untrained recruits; and its quality deteriorated when excellence was most required. Long service also tended to produce a class army, isolated from the life of the nation, and always a dangerous weapon in the hands of an unscrupulous ruler. Further, to condemn a man drawn by lot to lifelong service was felt to be incompatible with the maintenance of compulsory service; and when it was found by experience that soldiers could in three years be sufficiently trained for all purposes of war, and that by the application of short service armies could be trebled in numbers in war without increasing the cost in peace, the old long service armies disappeared from Europe.

The converse of this is the second, or *militia* system, actually in force in Switzerland and Canada, and to a certain extent in America. Under this no permanent army is maintained, but all, or a large proportion, of the inhabitants are liable to service, and undergo a partial training. The cost of such a force is very small, the industrial disturbance reduced to a minimum; yet the forces that are put in the field are formidable, in numbers at least. But its real economy is more than doubtful. History abounds with lessons that such forces can never carry on sustained operations against trained armies. They may show brilliant courage; but they want the mutual knowledge and reliance, the constancy in defeat, and the instinctive discipline which can be acquired by habit alone. The cost of putting them in the field is always disproportionately great. Opposed to trained armies, they invite defeat; opposed to similar forces, as in the great American war, decisive action on either side is impossible, and the war drags on till its cost far exceeds that of years of standing armies and peace preparations.

The third and intermediate system is that of *short service and reserves*, now adopted by all nations. The European details of its application vary, but the general principles are the same in all,—to maintain the cadres of a large army in peace, capable of expansion in war, and to keep the recruit in the ranks only so long as is necessary to make him a trained soldier, and then pass him into a reserve. It combines the numerical strength of the militia system with the organisation, training, and discipline of a long service army. Its practical application will be seen in describing the various armies of Europe.

The principles of *organisation* are comparatively simple. Organisation. Organisation is of two kinds, tactical and administrative; the first having reference to action on the battle-field, the second to general maintenance in peace as well as in war. Originally the two were often distinct; thus companies and regiments were originally administrative units, battalions tactical ones; and the two had not necessarily any connection. But the most perfect organisation is that which answers both purposes, and in this direction all modern improvements have tended; and as the battle-field is the ultimate object of all preparation, administrative considerations must give way to tactical ones when they clash, and all organisation must conform to the tactical requirements of the day. Great progress was made in this branch during the Revolutionary war. The origin of regiments and battalions has already been described. The first "mixed divisions," *i.e.*, divisions comprising troops of all arms, were formed in the Revolutionary armies of 1792, and in 1804 Napoleon organised "corps d'armée," each forming a complete army in itself, under the command of a marshal,—the necessity for such organisation arising from the size of his armies, which had grown beyond the immediate control of one man. This organisation was copied by other armies, and attained its highest perfection when combined by the Prussians with their territorial system—each corps d'armée being permanently located in and recruited from a particular province. A modern army usually comprises several such corps d'armée.

A Prussian *army corps*, which may be taken as the type of modern organisation, consists of a staff, two infantry divisions, a cavalry brigade, a regiment (seven batteries) of corps artillery, a regiment of engineers, and a number of administrative services. An *infantry division* consists of a staff, two infantry brigades, a rifle battalion, four batteries of artillery, and a regiment of cavalry. An *infantry brigade* consists of a staff and two regiments (six battalions); a *cavalry brigade* of a staff, three regiments (twelve squadrons), and a battery of horse artillery. The *engineers* comprise a pontoon train, a light field bridge train, a column of entrenching tools, siege materials, and a field telegraph; while nine reserve ammunition columns accompany the corps artillery. The administrative departments include the *commissariat*, charged with the supply of the troops, and having at its disposal five provision columns and a large amount of hired or requisitioned transport, and provided with a field bakery,—the *medical department*, consisting of a staff; three ambulance detachments, each having a staff of medical officers, 120 trained stretcher-bearers to attend to and carry off the wounded on the battle-field, a supply of medical stores, covers for wounded, and a number of ambulance waggons, fitted for the conveyance of wounded, and the medical staff attendants, tents, and all appliances for 12 field hospitals, each calculated to receive 200 wounded,—the *pay department*, charged with the military chest;—a *field post*, a depôt for sick and supernumerary horses, and other services. Such an army corps has a fighting strength of 25 battalions, or about 25,000 infantry, 5 regiments (about 3000) cavalry, and 96 guns, and a total strength of about 40,000 men, 12,000 horses, and 1400 waggons and wheeled vehicles.

The following table shows approximately the military resources of the great powers of Europe:—

Country.	Population.	Military Expenditure.	Army—Peace Footing.	Army—War Footing.			
				Active Army.	Depôt Troops.	Garrisons and Reserves.	Total.
Great Britain,	32,000,000	£23,000,000	190,000	225,000	95,000	350,000	670,000
France,	36,000,000	18,000,000	450,000	780,000	270,000	500,000	1,550,000
German Empire,	41,000,000	15,500,000	400,000	680,000	240,000	330,000	1,250,000
Russia,	82,000,000	21,500,000	750,000	850,000	150,000	300,000	1,300,000
Austria and Hungary,	36,000,000	10,500,000	275,000	600,000	150,000	220,000	950,000
Italy,	27,000,000	7,500,000	200,000	375,000	125,000	250,000	750,000

Note.—It is impossible to form anything but an approximate comparison, owing to the different conditions of service and varying organisation of the several armies. Under "depôt troops" are included all forces whose province it is to feed the active army. Under "garrisons and reserves" are included all forces organised for home defence, and not forming part of the field armies; but in several cases a large proportion of these are available as reinforcements to the active army if required. Only those forces that have received some training and have a permanent organisation are counted; thus the English volunteers are included, but not the German landsturm, or French reserves of the territorial army. The British troops serving in India have been included in the military forces of Great Britain, and the expenses borne on their account by the Indian revenue in the military expenditure; but not the native forces in India.

HISTORICAL SKETCH OF THE BRITISH ARMY.

The history of the military institutions of England may be divided into three principal periods, each marked by a system peculiar to itself: the Anglo-Saxon, or militia period, preceding the Norman Conquest; the feudal period, extending from that to the great Rebellion; and the period of standing armies, lasting from the Restoration to the present day.

Anglo-Saxon period.

Prior to the Norman Conquest the armed force of England was essentially a national militia. Every freeman was bound to bear arms for the defence of the country, or for the maintenance of peace. Military service was not a debt due to the king or earl, the obligation of a dependent to his lord, but the service owed by a free citizen to his country. To give some organisation and training to this levy, the sheriffs had authority to call out the contingents of their several shires for exercise. The thanes appeared on horseback, and the bulk of the people, armed with swords, spears, and heavy shields, or with bows and spears, formed the infantry. This force, termed the "Fyrd," was available for home service only, and could not be moved even from its county except in the case of invasion or great emergency; and it was principally to repel the invasions of Danes and others that its services were required. Yet even in those days the necessity of some more permanent force was felt, and bodies of paid troops were maintained by the king and some of the great earls at their own cost. Thus Canute kept up a household force (*huscarle*) of 6000 men, and paid troops also formed part of Harold's army at the battle of Hastings.

Norman Conquest and feudal system.

Although William professed to reign by right of inheritance, not of conquest, and to maintain the existing laws of the country, its military institutions underwent a rapid and complete change under him. The great slaughter of the Anglo-Saxon nobility at Hastings, and the frequent and unsuccessful revolts of the survivors, and consequent forfeiture of their estates, enabled William to make large grants to his followers; and with these he introduced the feudal system of military tenure. Henceforth military service was a debt due by the dependent or vassal to the lord of whom he held his land, not the free service rendered by a citizen to his country. And William took advantage of his exceptional position as a conqueror, and as the original granter of nearly half the lands of England, to carry the feudal system to a perfection which it had never attained on the Continent. Assuming that "the king is the universal lord and original proprietor of all the lands of the kingdom," he proceeded to divide the country into more than 60,000 military allotments or fees, to be held under tenure of "knight's service." By the conditions of knight's service the tenant of a fee was bound to attend his lord in war, with horse and arms, at his own cost, for forty days in each year,—the tenant of half a fee doing like service for twenty days. Where one man held many fees—and some of the great barons held several hundreds—he became responsible to the king as tenant-in-chief for military service in proportion to his grant, and required the same from his tenants.

This important change in the tenure of land and military system of the country was not effected easily or at once. To the original Saxon proprietors, who still held much of the land, the feudal system was a strange and intolerable burden. But the ever-growing preponderance of the Norman element, the dissensions among the Saxons themselves, which William skilfully made use of, the constant wars and revolts, and consequent necessity for improved military organisation, gradually overcame their resistance, and shortly before the Conqueror's death the new system was finally accepted throughout the country. Thus the king could command the services of 60,000 knights[1] and men-at-arms for forty days free of cost; and these feudal troops, unlike the Saxon levies, were bound to follow him anywhere. Such at least was the theory; but in practice modifications were soon introduced. Forty days might suffice to repel an invasion or crush a revolt, but not to prosecute a foreign war; moreover, many of the tenants' fees were subdivided, and the holders only liable to twenty or ten days' service. On the other hand, many holders of fees could not render personal service, or preferred submitting to a money penalty instead. Thus by mutual consent grew up a system of fines or "escuage," and with the money levied from those who failed to do service the king was able to hire mercenaries, or pay such of the feudal troops as were willing to prolong their service. From time to time proclamations and statutes were issued reminding the holders of knights' fees of their duties; but the immediate object was generally to raise money rather than to enforce personal service, which became more and

[1] The "knight of honour," the true knight, must not be confounded with the tenant of a knight-fee. Practically the latter were usually the "men-at-arms," only men of good family being admitted to the honour of knighthood.

more rare. Thus gradually departed the spirit of the feudal system, the principle that those who held the land should fight for it; armies lost their national character, the power of the king was increased, and the first steps laid towards the establishment of standing armies as instruments in his hand. The feudal system had not, however, abrogated the old Saxon levies, and while in the former we trace the source of our stipendiary forces, from the latter arose two national institutions,—the *posse comitatus*, liable to be called out by the sheriff to maintain the king's peace, and later the *militia* force. The *posse comitatus*, or power of the county, included all males capable of bearing arms, peers and spiritual men alone excepted; and though its primary object was to maintain peace and pursue felons under the command of the sheriff, it was also bound to attend upon summons for the military defence of the country. This levy was organised as an armed force by an Act of 27 Henry II. (1181 A.D.), and subsequently by the 13 Edward I. (1285 A.D.), commonly known as the "Statute of Winchester," which determined the numbers and description of weapons to be kept by each man according to his property, and also provided for their periodical inspection. This force was only liable to home service, but even in early days seems to have been used, as now, as a feeder to the army.

Under the Plantagenets. The armies with which our kings carried on their foreign wars consisted mainly of paid troops. Many, in the days of the earlier kings especially, were foreign mercenaries, and these were sometimes imported to England to the great discontent of the country. But the Edwards found that there was better material to be had in this country than abroad; and the army which Edward III. took to France, and with which he won the battle of Crecy, was composed exclusively of English, Welsh, and Irish. A muster-roll, still preserved, of the army with which he besieged Calais is interesting as giving the numbers and rates of pay of the different ranks. The prince received £1 a day, and the bishop of Durham, 6s. 8d. Then follow:—

13	Earls,	at 6s. 8d.	per diem.
44	Barons and bannerets,	at 4s.	,,
1,046	Knights,	at 2s.	,,
4,022	Esquires, captains, and leaders,	at 1s.	,,
5,104	Vintenars and mounted archers,	at 6d.	,,
15,480	Foot archers,	at 3d.	,,
314	Mechanics, gunners, &c., from 12d.	to 3d.	,,
4,474	Welsh foot,	at 2d.	,,

These armies were raised partly from those bound to serve by tenure, partly by forced levies, which, though illegal and often strenuously resisted by Parliament, were not unfrequent; but mainly by contracts entered into "with some knight or gentleman expert in war, and of great revenue and livelihood in the country, to serve the king in war with a number of men." Copies of the indentures executed when Henry V. raised his army for the invasion of France in 1415 are in existence. Under these the contracting party agreed to serve the king abroad for one year, with a given number of men equipped according to agreement, and at a stipulated rate of pay, the items of which are set forth, and agree generally with those given above. A certain sum was usually paid in advance, and in many cases the Crown jewels and plate were given in pledge for the rest. The profession of arms seems to have been a profitable one, and there was no difficulty in raising men where the commander had a good military reputation; Edward III. is said to have declined the services of numbers of foreign mercenaries, who wished to enrol under him in his wars against France. The pay of the soldier was high as compared with that of the ordinary labourer, and he had the prospect of a share of plunder in addition.

The funds for the payment of these armies were provided partly from the royal revenues, partly from the fines paid in lieu of military service, and other fines arbitrarily imposed, and partly by grants from Parliament. As the soldier's contract usually ended with the war, and the king had seldom funds to renew it even if he so wished, the armies disbanded of themselves at the close of each war. To secure the services of the soldier during his contract, Acts were passed (18 Henry VI. c. 19; and 7 Henry VII. c. 1) inflicting penalties for desertion; and in Edward VI.'s reign an Act "touching the true service of captains and soldiers" was passed, somewhat of the nature of a Mutiny Act.

Under Charles I. and the Commonwealth. The six centuries which elapsed between the Norman Conquest and the Rebellion may be treated as one period in the history of the military institutions of England. Though considerable changes had taken place, though the feudal armies in which the great nobles rode at the head of their retainers, and whose main fighting strength lay in the number of knights and men-at-arms, had given place to armies raised by contract, commanded by officers having no personal connection with the men, and in which the common infantry formed the real fighting strength, still these changes had taken place gradually, and fundamentally the principles remained the same. The army seldom came in collision with the nation. Latterly indeed, in Queen Elizabeth's time, the demands of the Irish wars had led to frequent forced levies, and the occasional billeting of the troops in England also gave rise to murmurs, but the brilliancy and energy of her reign covered a great deal, and the peaceful policy of her successor removed all immediate cause of complaint. But with the accession of Charles I. a new period commences, and we find the army a constant and principal source of dispute between the king and Parliament, until under William III. a standing army is finally established on its present constitutional footing. Charles wished to support his brother-in-law, the Elector Palatine, in his struggle for the crown of Germany, and for that purpose raised an army of 10,000 men. He was already encumbered with debts, and the Parliament refused all grants, on which he had recourse to forced loans to supply the funds. The army was sent to Spain, but returned without effecting anything, and was not disbanded, as usual, but billeted on the inhabitants. The billeting was in itself illegal, and was the more deeply resented as it appeared that the troops were purposely billeted on those who had resisted the king's loan. Finally, the disorders committed by these troops caused the king to issue a commission to certain persons, officers and others, to proceed against offenders "according to the justice of martial law,"—thus establishing martial law in England in time of peace. These three breaches of the law—forced loans, billeting, and martial law—all directly connected with the maintenance of the army, formed the main substance of the grievances set forth in the celebrated "Petition of Right." In accepting this petition, Charles gave up the right to maintain an army without consent of Parliament; and when in 1639 he wished to raise one to act against the rebellious Scotch, Parliament was called together, and its sanction obtained, on the plea that the army was necessary for the defence of England. This army again became the source of dispute between the king and Parliament, and later some of the hottest contests arose on the question of the command of the armed forces: finally both sides appealed to arms, and the parliamentary army, after having overthrown the monarchy, upset the Parliament also, and remained undisputed master. Under Cromwell, the force which had raised him to power was naturally augmented and encouraged. For the first time a real standing army, amounting at one time to 80,000 men, was maintained. This army of the Commonwealth differed in character from those which preceded or followed it, the men as a rule being taken from a better class, the officers from a lower one. The common levies of the first parliamentary armies were no match for the gentlemen who gathered round the royal standard, till Cromwell leavened them with a different stamp of men, mainly drawn from the yeomen and middle class, — earnest resolute men, whose stern fanaticism was able to turn the scale against the headstrong valour of the Royalists. This class served largely in Cromwell's army, and gave a tone to the whole, while the pay was sufficiently high to make it a desirable profession for others besides the poorest. But with the officers it was otherwise. The noble and gentle families who commanded the king's armies remained faithful to his cause, and Cromwell had to draw his officers from a class little above the men. Few will be found now to dispute Cromwell's capacity as a general and ruler, nor the high qualities of the army by which he maintained his power at home, and spread England's prestige abroad. But such an army could not be maintained without great cost and hardship to the people at large, and before Cromwell's death it had produced deeper discontent than even Charles's exactions.

On the Restoration this army was disbanded. The king feared and distrusted it, for it was formed of his enemies, and officered by men who had approved his father's execution, and it had made itself hateful to the nation. The permanent forces of the Crown were reduced to the "garrisons and guards" maintained by the king from the revenue allotted to him for carrying on the government of the country. The "garrisons" were commissioned to special fortresses,—the Tower of London, Portsmouth, &c. The "guards" comprised the sovereign's body guards (the "yeomen of the guard" and "gentlemen-at-arms," who had existed since the times of Henry VII. and VIII.); Monk's regiment of foot (now the Coldstream Guards), alone retained of the disbanded army; and two regiments of life guards and one of foot guards, raised principally from the cavaliers who had followed the king's fortunes. Even this small force, at first not exceeding 3000 men, was looked on with jealousy by Parliament, and every attempt to increase it was opposed. The acquisition of Tangiers and Bombay, as part of the dower of the Infanta of Portugal, led to the formation of a troop of horse (now the 1st Royal Dragoons) and a regiment of infantry (now the 2d or Queen's regiment), for the protection of the former; and a regiment of infantry (afterwards transferred to the East India Company, and now the 103d, or Bombay Fusiliers), to hold the latter. These troops, not being stationed in the kingdom, created no distrust; but when in 1670, on occasion of the Dutch war, 12,000 men were raised for the protection of the coasts, Parliament immediately petitioned that they should be disbanded as soon as peace was made. On several occasions during Charles's reign considerable armies were raised, but were mostly disbanded again when the occasion ceased. Several regiments, however, were added to the permanent force, including Dumbarton's regiment (the 1st or Royal Scots)[1] and the 3d Buffs; and on Charles's death in 1685 the total force of "guards and garrisons" had risen to 16,500, of whom about one-half formed what we should now call the standing army.

James II. was more obstinate than his predecessor in his efforts to increase the army, and Monmouth's rebellion afforded him the pretext. A force of about 20,000 men was maintained in England, and a large camp formed at Hounslow. Eight cavalry and twelve infantry regiments were raised, and given the numbers which, with few exceptions, they still bear. James even proposed to Parliament to disband the militia and further augment the standing army; and although the proposal was instantly rejected by the Commons, he continued to add to the army, and to billet them on the country, in defiance of the remonstrances of Parliament, till the Revolution deprived him of his throne and put an end to the contest. The army which he had raised was to a great extent disbanded, the Irish soldiers especially, whom he had introduced in large numbers on account of their religion, being all sent home.

The condition of the army immediately engaged the attention of Parliament. The Bill of Rights had definitely established that "the raising or keeping of a standing army within the kingdom, unless it be by the consent of Parliament, is against the law," and past experience made them very jealous of such a force. But James was making efforts to recover his throne, and seeking aid from France; Ireland and Scotland were disaffected, civil war was imminent, foreign war certain; and William had only a few Dutch troops, and the remains of James's army, with which to meet the storm. Parliament therefore sanctioned a standing army, trusting to the checks established on the power of the Crown by the Bill of Rights and Act of Settlement, and by placing the pay of the army under the control of the Commons. An event soon showed the altered position of the army. A regiment which was favourably inclined to James, and had therefore been ordered abroad, mutinied, and marched north, declaring for James. It was surrounded and compelled to lay down its arms; but William found himself without legal power to deal with the mutineers. He therefore applied to Parliament, and in 1689 was passed the first *Mutiny Act*, which, after repeating the provisions regarding the army inserted in the Bill of Rights, and declaring the illegality of martial law, gave power to the Crown to deal with the offences of mutiny and desertion by courts-martial. From this epoch dates the history of the standing army as a constitutional force.

Under William the army was considerably augmented. The old regiments of James's army were reorganised, retaining, however, their original numbers, and three of cavalry and eleven of infantry (numbered to the 28th) were added. In 1690 Parliament sanctioned a force of 62,000 men, further increased to 65,000 in 1691; but on peace being made in 1697 the Commons immediately passed resolutions to the effect that the land forces be reduced to 7000 men in England and 12,000 in Ireland. The war that quickly succeeded obliged Great Britain again to raise a large army, at one time exceeding 200,000 men; but of these the greater number were foreign troops engaged for the Continental war. On the peace of Utrecht the force was again reduced to 8000 men in Great Britain and 11,000 in the plantations (*i.e.*, colonies) and abroad. From that time to the present the strength of the army has been determined by the annual votes of Parliament, and though frequently the subject of warm debates in both houses, it has ceased to be a matter of dispute between the Crown and Parliament. The following table shows the fluctuations between that time and the present—the peace years showing the average peace strength, the war years the maximum to which the forces were raised:—

Peace.		War.	
Year.	Number.	Year.	Number.

Note.—Prior to 1856 the British forces serving in India are not included.

[1] This regiment has the oldest history of any in the world. Originally the "Scottish Guard" of the kings of France, it was formed in the 9th century, and constantly recruited from Scotland. In 1625 it was sent to England to attend the coronation of Charles I., and revisited it later to fight against the parliamentary army. On the Restoration it came permanently to England, and was named the 1st Royal Regiment.

During William's reign the small English army bore an honourable part in the wars against Louis XIV., and especially distinguished itself by its intrepidity at Steinkirk, at Neerwinden, and in the assault of Namur. Twenty English regiments took part in the campaign of 1694. In the great wars of Queen Anne's reign the British army under Marlborough acquired a European reputation. The cavalry, which had called forth the admiration of Prince Eugene when passed in review before him after its long march across Germany (1704), especially distinguished itself in the battle of Blenheim; and Ramilies, Oudenarde, and Malplaquet were added to the list of English victories. The army was permanently increased by one regiment of cavalry and eleven of infantry; and though the regiments were much reduced in strength during the following peace, the cadres remained untouched. During the reign of the first and second Georges an artillery corps was organised, and the army further increased by five regiments of cavalry and thirty-five of infantry. Fresh laurels were won at Dettingen (1743), in which battle twenty English regiments took part; and though Fontenoy was a day of disaster for the English arms, it did not lower their reputation, but rather added to it. Six regiments of cavalry and six of infantry shared under Prince Ferdinand the honours of the victory of Minden (1759), and the English infantry was especially thanked by the prince for its conduct on that occasion. About this time the first English regiments were sent to India, and the 39th shared in Clive's victory at Plassey. During the first half of George III.'s reign the army was principally occupied in America; and though the conquest of Canada may be counted with pride among its exploits, this page in its history is certainly the darkest. English armies capitulated at Saratoga (1777) and at Yorktown (1781), and the war ended in 1783 by the evacuation of the revolted states of America and the acknowledgment of their independence. Before passing to the great French Revolutionary wars, from which a fresh period in the history of the army may be dated, it will be well to review the general condition of the army in the century preceding.

Regiments were raised almost as in the days of the Edwards. The Crown contracted with a distinguished soldier, or gentleman of high position, who undertook to raise the men, receiving a certain sum as bounty-money for each recruit. In some cases, in lieu of money, the contractor received the nomination of all or some of the officers, and recouped himself by selling the commissions. This system—termed raising men for rank—was retained till very recently, and originally helped to create the "purchase system" of promotion. For the maintenance of the regiment the colonel received an annual sum sufficient to cover the pay of the men, and the expenses of clothing and of recruiting. The colonel was given a "beating order," without which no enlistment was legal; and was responsible for maintaining his regiment at full strength. "Muster masters" were appointed to muster the regiments, and to see that the men for whom pay was drawn were really effective. Sometimes, when casualties were numerous, the allowance was insufficient to meet the cost of recruiting, and special grants were made. In war time the ranks were also filled by released debtors, pardoned criminals, and impressed paupers and vagrants. Where the men were raised by voluntary enlistment, the period of service was a matter of contract between the colonel and the soldier, and the engagement was usually for life, but exceptional levies were enlisted for the duration of the war, or for periods of three or five years. The army was officered entirely from the upper ranks, the low rate of pay and the purchase system combining to exclude all but men of independent incomes. Appointments (except when in the gift of the colonel) were made by the King at home, and by the Commander-in-Chief abroad; even in Ireland the power of appointment rested with the local commander of the forces until the Union. The soldier was clothed by his colonel, the charge being defrayed from the "stock fund." The army lived in barracks, camps, or billets. The barrack accommodation in Great Britain at the beginning of the century only sufficed for 5000 men; and though it had gradually risen to 20,000 in 1792, a large part of the army was constantly in camps or billets—the latter causing endless complaints and difficulties. The drill of the army was mainly borrowed from that of Frederick, but the American war had trained many regiments to skirmishing. The administration was generally corrupt and defective, and the character of the army stood very low when England embarked on her long war with France.

Her first efforts in this war did not tend to raise it. After a campaign, fought with great gallantry but not much skill, the English army under the Duke of York was driven out of Holland, and that country annexed to France. But the appointment of the Duke of York to the post of Commander-in-Chief of the army was the commencement of a better era. He did much to improve its organisation, discipline, and training, and was ably seconded by commanders of distinguished ability. Under Abercromby in Egypt, under Stewart at Maida, and under Wellesley and Lake in India, the British armies again attached victory to their standards, and made themselves feared and respected. The energy and unbending resolution of Pitt seemed to communicate itself to the nation, and the threatened invasion of England excited her martial spirit to the highest pitch. Finally, her military glory was raised by the series of successful campaigns in the Peninsula, until it culminated in the great victory of Waterloo; and the army emerged from the war with the most solidly founded reputation of any in Europe.[1]

The events of this period belong to the history of England, and fall outside the province of an article dealing only with the army. The great augmentations required during the war were effected partly by raising additional regiments, but principally by increasing the number of battalions, some regiments being given as many as four. On the conclusion of peace these battalions were reduced, but the regiments were retained, and the army was permanently increased from about 20,000, the usual peace establishment before the war, to an average of 80,000. The Duke of York, on first appointment to the command, had introduced a uniform drill throughout the army, which was further modified according to Dundas's system in 1800; and, under the direction of Sir John Moore and others, a high perfection of drill was attained. At the beginning of the war, the infantry, like that of the Continental powers, was formed in three ranks; but a two-rank formation had been introduced in America and in India, and gradually became general, and in 1809 was finally approved.

Recent changes

In the Peninsula the army was permanently organised in divisions, usually consisting of two brigades of three or four battalions each, and one or two batteries of artillery. The Duke of Wellington had also brought the commissariat and the army transport to a high pitch of perfection, but in the long peace which followed these establishments were reduced or broken up. The period which elapsed between Waterloo and the Crimean war is marked by a number of Indian and colonial wars, but by no organic changes in the army, with perhaps the single exception of the Enlistment Act of 1847, by which short service,—*i.e.*, an original

[1] "Possédant les souvenirs de gloire et de succès les plus solides, sans contredit, parmi toutes les armées européennes."—(*L'Armée Anglaise*, by the Baron de Grancey, Paris, 1873.)

enlistment for 10 or 12 years, with power to re-engage to complete 21,—was substituted for the life enlistments hitherto in force. The army went to sleep on the laurels and recollections of the Peninsula. The Duke of Wellington, for many years Commander-in-Chief, was too anxious to hide it away in the colonies, and to save it from further reductions or utter extinction, to attempt any great administrative reforms. The force which was sent to Turkey in 1854 was an agglomeration of battalions, individually perhaps the finest the world had ever seen, but unused to work together, without trained staff, administrative departments, or army organisation of any kind. They fought with distinguished gallantry at the Alma and at Inkerman, but succumbed under the hardships, the privations, and the sickness of the winter before Sebastopol—a sacrifice to maladministration. The lesson was dearly bought, but was not thrown away. From that time successive War Ministers and Commanders-in-Chief have laboured perseveringly at the difficult task of army organisation and administration. Foremost in the work was Lord Herbert, the soldiers' friend, who fell a sacrifice to his labours, but not before he had done much for the army. The whole system of administration was revised. In 1854 it was inconceivably complicated and cumbersome. The "Secretary of State for War and Colonies," sitting at the Colonial Office, had a general but vague control, practically limited to times of war. The "Secretary at War" was the parliamentary representative of the army, and exercised a certain financial control, not extending, however, to the ordnance corps. The Commander-in-Chief was responsible to the sovereign alone in all matters connected with the discipline, command, or patronage of the army, but to the Secretary at War in financial matters. The Master-General and Board of Ordnance were responsible for the supply of material on requisition, but were otherwise independent, and had the artillery and engineers under them. The Commissariat Department had its headquarters at the Treasury; and the militia until 1852 were under the Home Secretary. A number of minor subdepartments, more or less independent, also existed, causing endless confusion, correspondence, and frequent collision. In 1854 the business of the colonies was separated from that of war, and the then Secretary of State, the Duke of Newcastle, assumed control over all the other administrative officers. In the following year the Secretary of State was appointed Secretary at War also, and the duties of the two offices amalgamated. The same year the Commissariat Office was transferred to the War Department, and the Board of Ordnance abolished, its functions being divided between the Commander-in-Chief and the Secretary of State. The minor departments were gradually absorbed, and the whole administration divided under *two* great chiefs, sitting at the War Office and Horse Guards respectively. Finally, in 1870 these two were welded into one, and the War Office as now existing was constituted.

Corresponding improvements were effected in every branch. The system of clothing the soldiers was altered, the contracts being taken from the colonels of regiments, who received a money allowance instead, and the clothing supplied from Government manufactories. The pay, food, and general condition of the soldier were improved; reading and recreation rooms, libraries, gymnasiums, and facilities for games of all kinds being provided. Special attention was directed to sanitary matters; large barracks were built on improved principles, more space allotted to the men; ventilation and drainage improved, and the rate of mortality greatly reduced. A large permanent camp was formed at Aldershott, where considerable forces were collected and manœuvred together. Various educational establishments were opened, a staff college established for the instruction of officers wishing to qualify for the staff, and regimental schools improved.

The Indian mutiny of 1857, followed by the transference of the government of India from the hands of the East India Company to those of the Queen's ministers, led to important changes. The East India Company's white troops were amalgamated with the Queen's army, and reorganised—a difficult task, and one which cannot yet be said to be completed.

Among recent alterations may be mentioned the localisation of the army, commenced in 1872, but which cannot produce its full effects for many years to come; the transference of certain powers over the militia from the lords-lieutenant to the Crown, in 1871, and the placing the militia and volunteer forces directly under the generals commanding districts; the abolition of purchase, in 1871; the introduction of short service (6 years in the ranks) by the Army Enlistment Act of 1870; the institution of annual autumnal manœuvres, at which considerable forces are collected and manœuvred against one another over extensive tracts of country; the formation of the Control Department, &c.; but these will be dealt with at length in the following pages.

British Army as it is.

Administration of the army

The supreme command of all the military forces of the nation is vested in the Crown, but can only be exercised through an intermediate and responsible agent. The entire administration, therefore, of the regular army and reserve or auxiliary forces is under the control and responsibility of the *Secretary of State for War*, who is assisted by two under-secretaries, the *Parliamentary* and *Permanent* Under-Secretaries of State. The actual army administration is divided among three great officers,—the Officer Commanding in Chief, the Surveyor-General of Ordnance, and the Financial Secretary. These officers are at the head respectively of the three great departments of the War Office, viz., the Military Department, the Control Department, and the Financial Department; their duties are defined by orders of Council of the 4th and 23d June 1870. The *Officer Commanding in Chief* is charged with "the discipline and distribution of the army, and of the reserve forces of the United Kingdom when embodied or called out for actual military service; the military education and training of the officers, non-commissioned officers, and men of the army, and of the reserve forces when assembled for training, exercise, inspection, or voluntary military duty; enlisting men for and discharging men from the army and army reserves; the collection and record of strategical information, including topography, in relation to the military circumstances of this and other countries; the selection of fit and proper persons to be recommended to Her Majesty for appointment to commissions in the army, for promotion for staff and other military appointments, and for military honours and rewards." The *Surveyor-General of the Ordnance* is charged with "providing, holding, and issuing to all branches of the army and reserve forces, food, forage, fuel, light, clothing, arms, accoutrements, munitions of war, and all other stores necessary for the efficient performance of their duties by such forces, of proper quality and pattern, and in proper quantities, according to the regulations governing the provision, custody, and issue of such supplies; exercising a strict control over the expenditure of such supplies, and seeing that they are properly accounted for by the several officers and others who may be charged with their custody, issue, and use; the custody of all buildings in which troops are quartered, and allotting quarters; providing transport for troops, and directing land and inland water transport, preparing the estimates for the above services, and causing the expenditure for them to be duly and carefully examined." The *Financial Secretary* is charged with "preparing the annual estimate for the pay of the army and reserve forces; collecting and incorporating into a general estimate for army services the estimates of the other departments of the War Office, and financially reviewing the expenditure proposed in such estimates; submitting for the instructions of the Secretary of State for War any proposed redistribution of the sums allotted to the different subdivisions of the votes for army services; finally, allowing all cash expenditure, and recording the same under its proper head of service in the annual account for Parliament; issuing all warrants for the payment of moneys, making all imprests to accountants and others, and seeing that accounts are duly rendered for the same; advising the Secretary of State on all questions of pay, retired pay, and pensions for the army and reserve forces." Any or all of the above-mentioned great officers may be in Parliament; and the Surveyor-General of Ordnance and Financial Secretary have usually seats in the Lower House.

Military Department.

The Officer Commanding in Chief is nominated by a letter of service, and holds his appointment during Her Majesty's pleasure, differing in this respect from the Surveyor-General and Financial Secretary, who are appointed by the Secretary of State, and removable at his pleasure. The appointment is therefore not a political one, and has been held by H.R.H. the Duke of Cambridge since 1856. He is assisted in his duties, and his orders are conveyed and executed through the agency of the *General Staff* of the army, comprising the Headquarter Staff of the Military Department at the War Office, and the general officers holding commands at home or abroad, with their subordinate staffs. The Headquarter Staff is subdivided into the *Adjutant-General's* Department, under the Adjutant-General to the Forces, a general officer of high standing, who is named directly by the sovereign, and is the chief staff officer of the Commander-in-Chief, and the channel through which all communications connected with the personnel, military operations, duties, discipline, and general efficiency of the army pass; the *Quartermaster-General's* Department,[1] under the Quartermaster-General to the Forces,—a general officer of subordinate rank to the Adjutant-General, but also appointed by the sovereign—whose duties embrace the movement and quartering of troops, roster of regiments for foreign service, and military questions connected with barracks; the *Military Secretary's* Department, under the military secretary to the Commander-in-Chief, who is the channel of correspondence on all matters connected with the appointment, promotion, exchange, and retirement of officers, and honours and rewards; the *Intelligence Department*, including the Topographical Department, under a Deputy-Adjutant-General, charged with the collection and registering of all strategical, statistical, and topographical information, whether relating to the British Empire or to foreign countries and armies; the *Recruiting Department*, under an Inspector-General of Recruiting, charged with the supervision of the recruiting throughout the kingdom; the *Auxiliary Forces Department*, under an Inspector-General of Reserve and Auxiliary Forces, embracing all questions connected with the militia, yeomanry, volunteers, and army reserves; and the *Military Education Department*, under the Director-General of Military Education, charged with the instruction and examination of officers, and matters connected with military colleges and regimental or garrison schools and libraries. The artillery and engineers have a distinct headquarter staff, subordinate, however, to the Adjutant-General.

Ordnance or Control Department.

The Surveyor-General of the Ordnance is appointed by the Secretary for War, and removable at his pleasure; the appointment is therefore a political one, and usually connected with a seat in Parliament. His subordinates and assistants in the performance of his duties are the staff of the Ordnance Department at the War Office, and the officers of the Control Department at the various military stations at home and abroad. The Ordnance Department is divided into the *Supply and Transport* Division, under a Director of Supplies and Transport, whose duties embrace questions connected with transport, food, forage, fuel and light, barracks, billets, and lodging; the *Artillery and Stores* Division, under a Director of Artillery and Stores, whose duties embrace all questions connected with the manufacture, maintenance, and supply of warlike stores of all kinds, and store and clothing accounts; the *Contracts* Division, under a Director of Contracts, who makes all necessary contracts at home, and examines those entered into abroad; and the *Clothing* Division, under the Director of Clothing, who has charge of the manufacture and supply of clothing for the army.

Finance Department.

The Financial Secretary is appointed by the Secretary for War, and removable at his pleasure; the appointment, like that of the Surveyor-General, is therefore a political one, and usually connected with a seat in Parliament. He is assisted by an Accountant-General and large staff of clerks in his department of the War Office, but has no staff or subordinates outside its walls.

Estimates.

The number of men to be maintained and the amount of money to be expended are determined by an annual vote of Parliament, based on the *estimates* laid before the House by the Minister of War. The minister, with the advice of the Officer Commanding in Chief, decides on the number of men that Parliament shall be asked to provide for the ensuing year, and the estimates are framed accordingly. To obtain the greatest possible accuracy, every subordinate department at home and abroad is called upon for a detailed statement of probable expenditure. These are examined and amended by the heads of the several departments and divisions at the War Office, and passed on to the Finance Department, where they are collected and incorporated into a general estimate, which is submitted to the Secretary of State, with the remarks of the Financial Secretary; and being revised and finally approved of, is submitted to the Treasury and included in the annual budget of the Chancellor of the Exchequer. The Treasury may, however, reduce any item that appears excessive. When the amount has been voted by Parliament, the Treasury authorises the Paymaster-General to honour the orders of the War Office to the extent of the vote. At home the necessary funds are obtained by warrants issued by the Accountant-General, under authority of the Financial Secretary, and paid by the Paymaster-General by means of orders upon the Bank of England; abroad they are obtained partly by remittances of specie, but principally by the negotiation of bills of exchange drawn upon the Lords of the Treasury by the local Control officers, acting in this respect on behalf of the Treasury. The army estimates, as laid before Parliament, are divided under a certain number of votes, and these again into sub-heads and items; and no money granted under one vote can be applied to a service included under another vote without the sanction of the Treasury. Within the limits of the vote, however, the War Office has the power of redistributing the sums allotted.

The following abstract of the army estimates for 1873–4 (which does not include, however, the cost of that part of the army which is serving in India), will indicate the classification under heads and votes, and the amounts allotted; and although these vary slightly from year to year, the general distribution of expenditure remains tolerably uniform:—

[1] The Adjutant- and Quartermaster-General's Departments have been recently amalgamated, but the subdivision of duties still remains.

1. *Regular Forces.*

Votes		
1.	Staff and Regimental Pay and Allowances	£5,072,500
2, 3, 4.	Divine Service, Law, and Medical Service	321,200
		£5,393,700

2. *Auxiliary and Reserve Forces.*

5, 6.	Militia and Yeomanry	£894,300
7, 8.	Volunteers—Army Reserve	553,500
		£1,447,800

3. *Control Establishments and Services.*

9.	Control Establishments, Wages, &c.	£389,000
10.	Provisions, Forage, Fuel. Transport, &c.	1,980,700
11.	Clothing Establishments and Services	743,100
12.	Supply and Manufacture of Warlike Stores,	1,070,000
		£4,182,800

4. *Works and Buildings.*

13.	Works, Buildings, and Repairs	£778,000

5. *Various Services.*

14, 15, 16.	Administration, Education, and Miscellaneous.	£363,700

6. *Non-effective Services.*

17, 18.	Pay of General Officers, and Rewards	£115,400
19.	Retired Officers—Full and Half Pay	527,900
20.	Widows' Pensions, &c.	147,300
21, 22, 23.	In and Out Pensions, and ditto for Wounds,	1,267,500
24, 25.	Superannuation Allowances	192,300
		£2,250,400

Total Effective and Non-Effective Services......£14,416,400

Enlistment of soldiers.

The whole of the military forces of England are raised by voluntary enlistment. Recruiting for the army is carried on partly by means of the large staff of non-commissioned officers attached to the brigade depôts, partly by means of pensioners receiving a special rate of pay while so employed, and partly by sergeants or parties sent out by regiments and corps for the purpose—the whole being under the superintendence of the colonel commanding the brigade district. Infantry regiments of the line recruit as far as possible within the districts to which they are attached; but the cavalry, artillery, engineers, guards, and rifles recruit throughout the country generally. Enlistment in the army is regulated by the annual Mutiny Act and the Army Enlistment Act; the former legalises the maintenance of an army, and lays down the number of men and manner of enlisting them; the latter fixes the period and conditions of service. By the Enlistment Act of 1870 men are enlisted for a first period of twelve years, which may be spent either entirely in the army, or partly in the army and partly in the reserve, as may from time to time be fixed by the Secretary of State for War. At present "short service" is fixed at six years in the army and six in the reserve for infantry, and eight years in the army and four in the reserve for the other branches. The Household cavalry, and a certain proportion in the other branches, are enlisted for "long service," *i.e.*, twelve years in the ranks.

On the completion of twelve years' army service, soldiers may be allowed to re-engage for nine years, making a total of twenty-one, at the end of which they are entitled to discharge with a pension. Those who are passed into the army reserve remain liable for the rest of their twelve years' engagement to be recalled into the ranks in case of war or national emergency, and to be called out for eight days' training in each year; but otherwise resume their positions as citizens, and are free to follow their callings.

A recruit for the army must be between 18 and 25 years of age, unmarried, free from physical infirmities, and of such height and chest measurement as may be laid down from time to time. The standard has frequently varied, having been used as a means of regulating the supply of recruits, but stood in 1873 at a minimum of 5 feet 5 inches for the infantry, 5 feet 6 inches for light cavalry and engineers, 5 feet 7 inches for gunners, and 5 feet 8 inches for heavy cavalry; the minimum chest measurement being 33 inches. For rifle regiments and for artillery drivers the standard is reduced to 5 feet 4½ inches, but increased chest measurement is required. Exceptions are also made in favour of artificers and others. When a recruit presents himself for enlistment he is asked certain questions as to age, and whether he has served before; if the answers are satisfactory, and he is otherwise suitable, he is given a shilling as enlistment money, and served with a notice warning him to attend before a magistrate for attestation. Within not less than twenty-four, and not more than ninety-six hours he is brought before the magistrate. If he then dissents from his enlistment, he may be discharged on payment of 20s. "smart money;" if he still wishes to enlist, he makes a declaration contained in the attestation paper as to his age, place of birth, trade, &c.; signs the attestation, and takes the oath of allegiance; and is thenceforth legally a soldier. No recruit, however, is finally accepted until he has been examined by a medical officer, and approved by an officer of rank detailed for the purpose. Formerly, recruiting was carried on largely at public-houses kept for the purpose; young men were entrapped by lying placards or by the misrepresentations of recruiting agents, and often enlisted whilst drunk, and then sent under escort to their regiments. Recently great improvements have been made in the recruiting service: the bounties formerly offered, and varying from £1 to £10, according to the demand for recruits, have been abolished, exaggerated placards forbidden, the recruiting taken away as much as possible from the public-houses, and the young soldier sent by himself to join his regiment. Under the system of long service the annual number of recruits required to keep up the army was from 8 to 10 per cent. of its strength, but in future the proportion will be largely increased. The average number actually raised annually was 16,000 in the ten years 1860–9, and 21,000 in the three years 1870–2; the largest number raised in any one year since the war being 28,000, in 1859.

Pay.

The rates of daily pay of the soldier and of the non-commissioned ranks are shown in the following table:—

Rank.	Infantry.		Cavalry.		Artillery.		Engineers	
	s.	*d.*	*s.*	*d.*	*s.*	*d.*	*s.*	*d.*
Private	1	0	1	2	1	2½	1	1½
Corporal	1	3	1	6½	2	1	2	1¼
Sergeant	1	11	2	3	2	9	2	9½
Colour-Sergeants & Staff-Sergeants, from	2	5	3	1	3	3	3	3½
to	3	3	3	7	4	2	4	7½

The Household cavalry, horse artillery, and some ranks of the foot guards, receive a higher rate of pay, and the engineers usually earn working pay in addition. Every soldier further receives a free ration of bread and meat, valued at 6d. Taking into consideration the value of the ration, lodgings, clothing, fuel, and light, the pay and allowances of the infantry private represent an average annual value of about £38, and that of the cavalry private about £41, exclusive of any prospective advantages in the way of pension; while the corporals and sergeants range from £45 to £70. Comparing this with the annual receipts of the average labourer, which range between £35 and £45 in different counties of England and Scotland, and are much lower in Ireland, and bearing in mind that the soldier as a rule is called on to do less work, it is evident that his position on the whole is not a disadvantageous one. In addition to the above, the soldier may earn 1d. a day good-conduct pay after 2 years' service, 2d. a day after 6 years', 3d. after 12 years', and 4d. after 18 years' service. The amount to which the soldier is entitled is indicated by "good-conduct badges" worn on the arm; but these, with the corresponding pay, are liable to forfeiture for misconduct.

Discharge and pension

A soldier may claim his discharge at the expiration of his first or second period of service; or he may be discharged before the expiration of his service, either by sentence of court-martial or by order of the Commander-in-Chief for misconduct, or as an indulgence at his own request, or on reduction of the army, or as an invalid, if found unfit for further service. A soldier discharged after 21 years' service is entitled to a pension varying from a minimum of 8d. a day for a private, to a maximum of 2s. 6d. a day for a non-commissioned officer; every good-conduct badge the soldier was in possession of, or would have been entitled to, at the time of discharge, adding a 1d. a day to his pension. A soldier discharged on the completion of his first period (12 years), or discharged at any time for misconduct, receives no pension. If discharged as an invalid, on account of unfitness for service, he receives a temporary or permanent pension, varying, according to the nature of the disability and the manner in which it arose, from a minimum of 6d. a day for a year, to the full pension given above. Pensions for wounds are given on a special scale, according to the nature of the wound, the maximum being 2s. 6d. for a private and 3s. 6d. for a non-commissioned officer. Soldiers are also allowed to purchase their discharge as an indulgence, according to a fixed scale depending on length of service and character; £35 in the artillery and engineers, and £20 in the infantry being the maximum rates. After from 12 to 16 years' service such discharge is granted free.

Officers.

There are ten ranks of combatant officers in the army,—viz., field-marshals, generals, lieutenant-generals, and major-generals (classed as *general officers*); colonels, lieutenant-colonels, and majors (*field officers*); captains, lieutenants, and sub-lieutenants (regimental or *company* officers). The classification and promotion of officers is complicated by the system of *brevet* or *army* rank, by which an officer may hold a higher rank in the army than he holds in his regiment. Brevet rank is usually given for distinguished service in the field, or for length of service: it begins with the rank of major, and may be said to cease with that of major-general, as in that grade and in those above it all rank is army rank. Relative rank and command within the regiment, regimental promotion and duties, and pay, are determined by regimental rank; but rank, command, and duties outside the regiment, and army promotion, are governed by army rank. Thus a regimental captain may receive the brevet of major for distinguished service: he is called captain and brevet major, retains his place among the captains of his regiment, and continues to perform a captain's duties in his regiment; but on any duties where the officers of several regiments are mixed he takes his place as major, and would command captains of his own regiment, though senior as such to himself.

Purchase system.

Previous to November 1871 first appointments and regimental promotion in the cavalry and infantry were made under the purchase system. This system dates from the earliest days of the army, and arose partly from the mode in which regiments were originally raised. Every regimental commission had a fixed regulation price, varying from £450, the price of an ensigncy in an infantry regiment, to £7250, that of a lieutenant-colonelcy of Life Guards; in addition to which an over-regulation price, which sometimes even exceeded the regulation price, had sprung up, and become established by custom, though contrary to law. An officer on retiring received the regulation price of his commission from Government, and the over-regulation from the officer who succeeded him; and the step went to the senior qualified officer of the lower grade in the regiment who was able and willing to purchase it. An officer who could not afford to purchase rose with the others till he became senior of his rank, and there remained till a death vacancy or other "non-purchase step" gave him his promotion. Practically, however, the injury inflicted was less than at first sight appears, as the purchase system stimulated a rapid flow of promotion, by which the non-purchase officer profited also, and if he lost a year or two in promotion, he saved several thousand pounds. First appointments were given to gentlemen whose names were on the Commander-in-Chief's list, and to cadets from the Military College at Sandhurst, on passing the required examinations and paying the price of the commission; a certain number of commissions without purchase being given to those who passed high examinations at Sandhurst, and to young men whose fathers' services gave them special claims.

Purchase was abolished by warrant of 20th July 1871, Parliament voting the money to compensate the officers then holding saleable commissions, and a system of promotion by "seniority tempered by selection" was substituted by the present regulations.

First appointments.

First commissions as sub-lieutenants are now given to successful candidates at an open competitive examination, to non-commissioned officers specially recommended, to university students who have passed certain examinations, and to "Queen's" and "Indian cadets," and pages of honour. A certain number of first commissions as lieutenants are also given to lieutenants of militia regiments. The limits of age for candidates by competition are from 17 to 20; but this is extended to 22 in the case of university students and militia lieutenants, and 30 in the case of non-commissioned officers. The great majority of first appointments are given by open competition, examinations for the purpose being held periodically under the Civil Service Commissioners. The successful candidates receive commissions as sub-lieutenants, and are sent to the Military College at Sandhurst (or to their regiments, if in India) for a course of instruction; and after passing the required examination in military subjects at the conclusion of the course, and serving a certain time with their regiments, are eligible for promotion to the rank of lieutenant.

Promotion.

A lieutenant is eligible for promotion to captain after two years' service, but the actual time is usually much longer—from eight to eleven years; to qualify, he must pass an examination in regimental duties, drill, &c., and also a special army examination in military law, tactics, field sketching, and field fortification. Promotion to the rank of captain is usually by regimental seniority; the senior qualified subaltern in the regiment succeeding to a vacancy among the captains. A captain may become *regimental* major by succession to a vacancy in his own regiment, or by being promoted to a majority in another regiment, or on half-pay; and *brevet* major by promotion for distinguished service, or by seniority in the army. Before promotion to a regimental majority a captain must pass a practical examination in subjects connected with the command of a regiment or of a small mixed force in the field. The appointment as major to a regiment is made for five years only, but is renewable. A major may become *regimental* lieutenant-colonel by appointment to the command of a regiment, or to an unattached lieutenant-colonelcy; and by *brevet* for distinguished service, or by seniority in the army. Certain staff appointments also carry with them the rank of lieutenant-colonel on appointment, or on completion of five years' service in them. Regimental promotion ceases with the rank of lieutenant-colonel. When a vacancy arises in a regiment by death or by the promotion of an officer to another regiment, the step goes in the regiment; if it arises otherwise, it is filled up as seems best to the Secretary of State and the Commander-in-Chief,—regimental considerations, however, receiving full consideration. A lieutenant-colonel becomes colonel by *brevet*, by promotion for distinguished service, on appointment as aide-de-camp to the Queen, after five years' service in the command of a regiment, or an equivalent staff appointment, or eight years under certain conditions.

The promotion of general officers is by seniority, regulated by a fixed establishment, the numbers of which in 1870 were 71 generals, 115 lieutenant-generals, and 188 major-generals.[1] Promotions may, however, be made independently of the establishment for distinguished service. Field-marshals are appointed at the will of the sovereign, and without reference to seniority.

All promotions are made upon the recommendation of the Commander-in-Chief, with the approval of the Secretary of State for War.

Artillery and Engineers.

The Artillery and Engineers have always been on a different footing from the rest of the army. First appointments to these services are made through the Royal Military Academy, entrance to which is by open competitive examination. After a course of instruction in professional subjects, occupying three years, cadets are examined and finally classed, and receive commissions in the engineers and artillery according to their standing on the list. Those selected for the engineers are required to go through a further course of instruction at Chatham for two years before their commissions are confirmed. Regimental promotion in the two services is governed purely by seniority, and a separate establishment of general officers is maintained for them; in brevet promotion they are on the same footing as officers of the other branches.

Pay.

The rates of pay of the several ranks are shown in the following table:—

Rank.	Household Cavalry.	Foot Guards.	Infantry.	Cavalry.	Artillery.	Engineers.
Gen. Officer, a Colonel of a Regiment or Col. Commandant (annual).	£ 1800	£ 2000 or 2200	£ 1000	£ 1350[2]	£ 994	£ 990
General Officer, not a Colonel.........(annual).	450	450	450	450	450	450
Colonel..............(daily).	...	...	...	...	1 6 0	1 6 0
Lieut.-Colonel... "	1 9 2	1 6 9	0 17 0	1 3 0	0 17 11	0 17 11
Major.............. "	1 4 5	1 2 0	0 16 0	0 19 3	0 16 0	0 10 0
Captain............ "	0 15 1	0 15 6	0 11 7	0 14 7	0 11 0	0 11 0
Lieutenant....... "	0 10 4	0 7 4	0 6 6	0 9 0	0 6 10	0 6 10
Sub-Lieutenant.. "	0 8 0	0 5 6	0 5 3	0 8 0	0 5 7	0 5 7

Officers of the horse artillery receive a higher rate of pay, slightly in excess of that of the corresponding ranks in the cavalry. Officers of the engineers, doing duty as such, receive extra pay, usually amounting to one-half of their ordinary pay if serving at home, or equivalent to it if serving abroad or in the London district. Lieutenant-colonels of regiments, and other officers holding commands of wings, batteries, or depôts, receive "command pay" of from 3s. to 1s. 6d. daily. Captains holding higher rank by brevet receive 2s. a day additional; and lieutenants, after seven years' service, 1s. a day. Officers holding staff appointments receive the pay of such appointments in addition to their regimental pay or half-pay.

Officers holding certain appointments are "seconded"—that is, their place in the regiment is filled up, and they become supernumerary, their names being shown in italics in the *Army List*; but they still belong to the regiment, and rise in it in due course.

Officers who entered the purchase corps under the old system can retire by the sale of their commissions, receiving from Government the value, over-regulation as well as regulation, of the commission which they held at the date of the abolition of purchase. Within certain limits officers are allowed to retire on the full pay of their rank after thirty years' service,—the full pay of a lieutenant-colonel being reckoned at 20s. a day; and all officers have an unqualified right to retire on half-pay after twenty-five years' service. The rates of half-pay amount usually to about three-fifths of the full pay of the corresponding ranks. Pensions are granted to officers who have received wounds in action equivalent to the loss of a limb, at the rate of £400 a year to a lieutenant-general, £300 to a colonel or lieutenant-colonel, £200 to a major, £100 to a captain, and £70 to a lieutenant. Such pensions continue as long as the effects of the wound continue, and are held in addition to any pay or retiring allowances the officer is in receipt of. Gratuities, varying from three to twelve months' pay of the rank, are granted to officers who have received less serious wounds.

Retirements and Pensions.

Pensions are granted to the widows of officers killed in action, or dying of diseases contracted in the field, at rates varying from £60 (lieutenant's widow) to £200 (widow of colonel or lieutenant-colonel) in the former case, and £50 to £150 in the latter; and "compassionate allowances" are granted, at rates varying, according to rank of deceased officer and other circumstances, from £6 to £40 annually for each child. Such compassionate allowances, however, are not granted except in cases where it is shown that the means of the family are so limited that they actually require such assistance; and widows' pensions generally cannot be claimed as a right, and are not granted where the widow is left in affluence, or where the Secretary of State sees reason to withhold them on account of misconduct or other causes. A reduced rate of pension and compassionate allowances, ranging from £40 to £120 for the widow, and £5 to £20 for each child, is granted where the officer died under circumstances which do not entitle his family to the higher rates; but in such case the aggregate amount must not exceed the half-pay of the rank held by him at the time of his death. When an officer holding a saleable commission is killed in action, or dies within six months of wounds received, his family receive the value of such commission.

Strength, Composition, and Distribution of the Military Forces of the Empire (1873).

A. Regular Army—British Troops.

Description of Force.	Officers.	Non-Com. Officers and Men.	Troop Horses.	Guns.
Combatants.				
General Staff.......................	77	...	...	...
Cavalry, 31 Regiments..............	884	16,389	11,586	...
Artillery, 30 Brigades..............	1416	33,366	13,350	674
Engineers, 40 Companies, 3 Troops..............	793	4,856	422	...
Infantry, 148 Battalions, 70 Brigade Depôts..................	5298	120,169	...	...
Total Combatants	8468	174,780	25,358	674
Non-Combatants.				
Control Department and Army Service Corps..................	512	3,006	1,087	...
Medical Department and Army Hospital Corps................	1021	1,324	...	...
Chaplains' Department.............	78	...	...	...
Miscellaneous........................	93	546	...	...
Total Non-Combatants	1704	4,876	1,087	...

Total of all ranks, 189,828; of these 62,924 serving in India, 21,470 in the colonies, and 105,434 at home.

[1] The guards and line, artillery, engineers, and marines, have each their separate list. The total establishment will be increased by promotions from the Indian staff corps.

[2] In future to be only £1000.

B. Reserve and Auxiliary Forces.

	All Ranks
1st Class Army Reserve	7,993
2d ,, ,, ,,	23,804
Militia Artillery	15,735
,, Infantry	123,283
Yeomanry Cavalry	15,086
Volunteers—Artillery	30,750
,, Infantry, Mounted Rifles, &c.	130,000
Total Reserve and Auxiliary Forces	346,651

The addition to this of the regular army at home, 105,434, gives as the total of forces, active and reserve, within the United Kingdom, 452,085.

C. Indian and Colonial Troops.

	Men.	Horses	Guns
Indian Native Army.			
Infantry, 130 Battalions	101,134	...	...
Cavalry, 37 Regiments	18,575	13,587	...

Lascars, Hong-Kong and Ceylon	264	...	...
Total Indian and Colonial Troops	127,449	14,210	36

D. Colonial Militia, Volunteers, and Reserve Forces.

	Men.	Horses.	Guns.
North American Confederation	52,414	2081	48
West Indies	3,952	610	24
African Colonies	4,343	1143	19
Possessions in Asia	2,116	120	6
Australian Colonies	19,055	1703	43
Total	81,880	5657	140

Note.—The contingents furnished by Native Indian States under our protection are not included in the summary of our Indian forces; and the disembodied or untrained militia of Canada, amounting to about 600,000 men, has not been taken into account in the summary of Colonial Reserve Forces.

Staff.

The staff of the British army may be classed under three principal heads—

1. General Officers, commanding divisions, districts, brigades, &c.;
2. General Staff, including Adjutant-General and Quartermaster-General's Departments, brigade-majors, &c.;
3. Personal Staff, consisting of military secretaries and aides-de-camp.

Appointments to commands are made from the lists of superior officers of corresponding rank. Sometimes, however, commands are given to officers of lower rank than that of the appointment, in which case they receive local and temporary rank The command of brigades is usually given to colonels, with temporary rank of brigadier-general.

General officers are responsible for the discipline and efficiency of all the military forces within their commands. They are required to make annual inspections of every regiment or corps, and report minutely on them for the information of the Commander-in-Chief. They are assisted in their duties, and their orders conveyed to the troops, by the officers of the staff. Officers for the *General Staff* are selected exclusively from the regular army, and, except in cases of proved abilities in the field, must have passed through the Staff College. Admission to the Staff College is obtained by competitive examination, the number entering being limited to twenty annually. Candidates must have served not less than five years, and be reported to be thoroughly good regimental officers, qualified from general character, disposition, &c., for employment on the staff, and physically fit for its active duties. Before being allowed to compete, they are reported upon by a board consisting of the commanding officer and two next seniors of their regiment and corps, and also by a general officer, to whose staff they have been attached for a month on trial. Officers of not less than seven years' service may present themselves at the final examination without having studied at the college; but the same qualifications and certificates are required from them. After completing the course and passing the final examination, officers are attached during the following summer drill season either to the staff of a general officer, or to the other arms of the service.

Officers appointed to the *Personal Staff* are not required to pass through the Staff College, but have to undergo a qualifying examination.

Staff appointments are held for five years only, at the end of which time the officer reverts to his regiment or to half-pay. Most of the lower appointments are held by regimental officers who are temporarily withdrawn from their regiments, but still borne on its establishment. No effective field officer of a regiment, however, can hold a staff appointment, and no regiment of cavalry may have more than one captain and one subaltern, and no battalion of infantry more than two captains and two subalterns on the staff.

The following table shows the principal ranks and rates of pay of the staff of the army:—

		£	s.	d.
General	(daily pay)	£5	13	9
Lieutenant-General	,,	3	15	10
Major-General	,,	1	17	11
Brigadier-General	,,	1	8	6
Colonel on the Staff	,,	1	2	9
Adjutant- or Quartermaster-General	,,	1	17	11
Deputy do. do.	,,	0	19	0
Assistant do. do.	,,	0	14	3
Deputy-Assistant-, Adjutant- or Quartermaster-General, Brigade-Major, Assistant Military Secretary, or Aide-de-camp	,,	0	9	6

The Headquarter Staff receive a special higher rate of pay. These rates are in addition to the pay or half-pay of their regimental commissions. Staff officers also receive an allowance for horses, varying from two for the lowest ranks to eight for a general.

The staff are the assistants of the general in all his duties, and the channels through which his orders are conveyed to the troops. The duties of the officers of the Adjutant-General and Quartermaster-General's Departments, and of military secretaries, correspond generally to those of the same departments at headquarters; the Adjutant-General and his deputies or assistants being charged with the issue of all orders, and matters referring to drill, discipline, returns, duties, &c.; the Quartermaster-General, or his subordinates, with matters connected with the movement and quartering of troops, camps, military positions, reconnaissances, embarkations, and disembarkations, &c.; and the military secretaries with questions relating to promotions and appointments, miscellaneous confidential correspondence, and communications with the civil authorities. A brigade-major performs the duties of the Adjutant and Quartermaster-General's Departments within his brigade. The duties of an aide-de-camp are of a more personal nature. In the field he is employed to carry orders, &c.; in peace he attends his general at inspections and on all public occasions, and renders such services as his general requires of him. Officers of the General Staff, as a rule, are not under the rank of captains; aides-de-camp are appointed without regard to rank, but no officer may hold a staff appointment till he has served three years with his regiment or corps. Appointments to the General Staff are made by the Commander-in-Chief by selection from the qualified officers; appointments on Personal Staff are made on the recommendation of the general officer. The total numbers of officers employed on the staff of the army are 241 in the United Kingdom and colonies (British establishment), and 278 in India (Indian establishment). About two-thirds of the staff on the British establishment belong to regiments, and are borne on their establishments, the remainder being officers on half pay or unattached. In India the rules regarding staff appointments vary a little, and most of the appointments, with the exception of the higher commands, are filled from a special "staff corps;" but some are also held by officers from the British regiments serving in India.

Cavalry.

The cavalry consists of 31 regiments: viz., 2 of Life Guards and 1 of Royal Horse Guards, forming together the "Household Brigade;" 7 regiments of Dragoon Guards, 3 of Dragoons, 5 of Lancers, and 13 of Hussars.

The Household Brigade form the body-guard of the sovereign, furnishing the escorts on all state occasions. They are recruited regimentally, and take none but picked men, of good character, and over 5 feet 10 inches in height. They wear helmet, cuirass, and long jack-boots, and are armed with a breech-loading carbine and long straight sword, 40 inches in the blade. From the great size of the men, added to the weight of the cuirass, they ride very heavy—from 21 to 22 stone when equipped for service. They are quartered in or near London, and are only sent abroad in war.

The other regiments are classed as "heavy," "medium," and "light." The dragoons are classed partly as heavy, and partly as medium; the lancers as medium; the hussars as light. The heavies recruit from men of 5 feet 8 inches to 5 feet 11 inches in height, and ride, in "service marching order," from 19 to 20 stone; the mediums from men of 5 feet 7 inches to 5 feet 9 inches, and ride from 18½ to 19 stone; the lights from men of 5 feet 6 inches to 5 feet 8 inches, and ride from 17½ to 18½ stone. The dragoon guards, dragoons, and hussars are armed with breech-loading carbines and sword. The lancers carry a bamboo lance (9 feet long), sword, and pistol. The colour and facings of the uniform vary in different regiments, the dragoons mostly wearing red, while the hussars and lancers wear blue. The dragoons wear helmets, with the exception of the 2d Dragoons (the "Scots Greys"), who wear bearskins; the lancers, the lancer square-topped cap; and the hussars, a busby with plume and bag. The Household Brigade are the only cuirassed regiments.

A regiment of cavalry on war footing consists of 8 troops, forming 4 squadrons in the field, and numbering 1 lieutenant-colonel, 1 major, 8 captains, 12 lieutenants and sub-lieutenants, 5 regimental staff officers, 11 staff sergeants, 8 troop sergeants-major, 24 sergeants, 32 corporals, 8 trumpeters, 20 farriers, shoeing smiths, and saddlers, and 504 privates; in all, 27 officers and 607 men, with 559 horses. They take with them in the field 2 forge-waggons, 1 small-arm ammunition-cart, and 7 baggage and store-waggons. The peace establishment is 29 officers, 506 men, and 320 horses. Of the 28 regiments of the line, 9 are usually in India, and 19 at home. The principal cavalry stations in the United Kingdom are Aldershott, the Curragh (with Newbridge), and Dublin; at each of the two first there is a general commanding the cavalry, who also inspects all the cavalry regiments in that portion of the kingdom. The depôts of regiments serving abroad, and the riding establishment, are at Canterbury. Cavalry regiments are not connected with particular counties or districts, but recruit throughout the kingdom

The horses for the cavalry are mostly obtained by purchase from dealers, at the headquarters of the several regiments; no breeding establishments or special arrangements for securing a sufficient supply of a good class of horses, such as have been generally introduced on the Continent, exist in England. The horses are usually bought at four years old, £40 being the maximum government price; the average height is 15 hands 2 inches. Officers provide their own chargers, but are allowed to select from the troop horses under certain restrictions and on payment of £50; sub-lieutenants are provided with horses and horse equipments at the public expense.

The oldest cavalry regiments are the Horse Guards, raised by the Earl of Oxford, and first known as the Oxford Blues; and the two regiments of Life Guards, raised in 1661-2. The privates in these regiments were for the most part of good family, and were addressed as "Gentlemen of the Life Guards." The youngest regiments, the 19th, 20th and 21st Hussars, were formed from the European regiments in the East India Company's service at the time of the amalgamation.

Artillery.

The artillery, notwithstanding the great augmentations it has received of late years, consequent on the increased importance of its arm, still retains the title of the "Royal Regiment of Artillery." It consists of 205 batteries, forming 28 brigades, of which 5 brigades, or 31 batteries, are horse artillery; 10 brigades, or 83 batteries, are field artillery; and 13 brigades, or 91 batteries, are garrison or siege artillery. In addition to these, there is a depôt brigade of 12 batteries, and the "coast brigade" of 10 batteries. The battery is the true unit of our artillery, the brigade being rather a grouping for administrative purposes; in the field and horse artillery, the batteries are almost entirely independent.

The establishment of a battery of *horse artillery* on war footing is—1 major, 1 captain, 3 lieutenants, 1 assistant-surgeon, 1 veterinary surgeon, 2 staff sergeants, 6 sergeants, 12 corporals and bombardiers, 2 trumpeters, 10 artificers (including shoeing smiths), and 153 gunners and drivers; altogether 7 officers and 185 men, with 206 horses and 6 guns, 9 ammunition-waggons, and 5 forge, store, &c., waggons. The peace establishment varies; the present home establishment is 5 officers, 151 men, and 113 horses. The guns now in use are 9-pounder rifled muzzle-loaders, of wrought iron. In the horse artillery every man is either mounted, or carried on the limber or ammunition-waggons, to enable them to keep pace with cavalry.

A battery of *field artillery* on war footing has the same establishment of officers and non-commissioned officers, but more gunners and drivers, and fewer horses. The numbers are—7 officers, 197 men, 184 horses, 6 guns, 12 ammunition and 4 miscellaneous waggons. The peace establishment at home is 5 officers, 152 men, and 85 horses. The guns in use are 16-pounder rifled muzzle-loaders, drawn by 8 horses.

A *garrison battery* consists of 1 major, 1 captain, 2 lieutenants, 1 staff sergeant, 5 sergeants, 10 corporals and bombardiers, and 140 gunners. They are all dismounted, and are employed in garrisons in working the heavy guns, at sieges, and on other similar duties.

Besides the above, heavy batteries of position, mountain batteries, and ammunition columns are formed in war time. A heavy battery has 4 guns only, 40-pounder breech-loading rifled guns on the Armstrong principle. Mountain batteries are only organised when the nature of the warfare requires it, and their detail varies accordingly.

Artillery and infantry reserve ammunition columns are formed when an army takes the field, one being attached to each division. Their establishment is 4 officers and 138 men, with 4 artillery and 16 small-arm ammunition-waggons, 2 spare gun-carriages, 5 miscellaneous waggons, and 142 horses; carrying 360 rounds of gun, and 307,200 of small-arm ammunition.

The *coast brigade* is formed entirely of old soldiers of good character, drawn from the other brigades. It is broken up in small detachments, often numbering one or two men only, distributed along the coast; the men being employed to take charge of unoccupied forts and batteries, and of the guns and artillery stores in those which are occupied. The number of officers in the coast brigade is small, but there are 121 *master gunners*, ranking as warrant officers, attached to it, who take charge of the more important works and command the small detachments of coast brigade men.

The uniform of the whole of the artillery is blue with red facings; the horse artillery wear a jacket, the others a tunic. The head-dress for all is a busby with bag. The non-commissioned officers and gunners of the horse artillery, and the mounted men of the field batteries, are armed with the cavalry sword, the dismounted men with a sword-bayonet; the drivers carry no arms. Twelve carbines are carried with each horse battery, and 24 with each field battery. The garrison batteries are armed with breech-loading carbines and sword-bayonets.

The headquarters of the artillery are at Woolwich, the great arsenal for the whole kingdom. Two or three brigades are usually stationed there, besides the permanent depôt and riding establishment. Three horse brigades (15 batteries), six field brigades (43 batteries), and four garrison brigades (28 batteries) are stationed in India; four garrison brigades (28 batteries) in our colonies and foreign garrisons,—Gibraltar, Malta, Bermuda, Halifax, &c.; and the remainder distributed throughout the United Kingdom. The principal artillery stations besides Woolwich are Aldershott, Portsmouth, Dover, Dublin, and Plymouth. There is a second depôt at Sheerness; and a school of gunnery, with an extensive establishment, has been formed at Shoeburyness, for the double purpose of instructing officers and men in the higher branches of gunnery, and carrying on artillery experiments—the long reaches of sand near the mouth of the Thames being peculiarly favourable for this purpose.

The artillery are not connected with particular districts or counties, but recruit generally throughout the kingdom. The horses for the artillery are obtained by purchases made from dealers, or by officers specially appointed for the purpose, £45 being the maximum price allowed.

Engineers.

For purposes of administration, promotion, &c., the Royal Engineers form a single regiment or corps, consisting of 40 companies, 3 troops, and a large establishment of officers, not attached to any companies, but employed in superintending works and buildings, and in other professional and scientific duties. Of the 40 companies, four are "survey" companies, and two are attached for service with the postal telegraph; the remainder are employed in works and buildings, or undergoing instruction at Chatham. The war establishment of a company is 1 captain, 3 subalterns, 1 assistant-surgeon, 6 sergeants, 12 corporals, 2 buglers, and 100 privates (termed "sappers") of various trades, viz., carpenters, masons, bricklayers, smiths, painters, printers, telegraphists, &c.; in all, 5 officers and 120 men. The peace establishment is 3 officers and 93 men.

The three engineer troops are,—the field equipment troop, telegraph troop, and pontoon troop, each of which forms the nucleus of several similar ones to be raised in war. The war establishment of a *field equipment troop* is 6 officers and 233 men (of whom 100 are drivers), with 186 horses and 33 waggons and carts. It is divided into three sections, each of which carries the camp equipment and all necessary tools and implements for a company of engineers, and a "field park." The troop is kept together for convenience in peace time, but in the field would be broken up, and the sections attached to the companies of engineers. The field equipment troop carries mining and entrenching tools, sandbags, rope, gunpowder and fuses for mines and blasting, a portable forge, sets of carpenters', smiths', farriers', stonemasons', bricklayers', collar-makers', &c., tools and materials; also instruments, drawing materials, printing-press, and photographic apparatus.

A *telegraph troop* consists of 6 officers, 245 non-commissioned officers and men, with 24 carriages, 42 riding and 114 draught horses. Twelve of the waggons are fitted as wire waggons, and carry each three miles of insulated wire, on rollers, besides staples and telegraph poles for carrying the wire along trees or houses, or over obstacles. Four waggons are fitted as offices, with recording instruments (Morse). The troop is so organised that it can be broken up into three sections, each complete in itself. A certain proportion of the men are trained to act as signallers, and all the materials for visual signalling—flags for use by day, rockets and lime-lights for flashing signals by night—are carried with the troop.

A *pontoon troop* consists of 6 officers and 296 non-commissioned officers and men, with 31 carriages, 20 riding and 210 draught horses. It carries 22 pontoons, being sufficient to construct 120 yards of bridge, capable of bearing cavalry, infantry, and field artillery; and a supply of trestles for light field bridges.

It is further in contemplation to organise a railway battalion, composed of men trained to all duties connected with the construction, repair, and working of railways.

The daily pay of the several ranks has been already given; but in addition to this ordinary rate, officers, when regimentally employed, receive extra pay, usually equal to the ordinary pay, if abroad (or in the London district), or to one-half of it if at home; and the non-commissioned officers and men receive "working pay," varying according to their skill and to the nature of their employment, but commonly ranging between 1s. and 2s. a-day. The uniform of the Royal Engineers is scarlet, with blue facings, the head-dress a low busby and plume. The men are armed with a Lancaster breech-loading rifled carbine and sword-bayonet. In the engineer train the non-commissioned officers and sappers carry swords; the drivers carry no arms.

The sappers are recruited entirely from men of good character, able to read and write, and who have been brought up to, or served apprenticeship in, some suitable trade. All men on enlistment are sent to Chatham to go through a long course of training and instruction in the special duties connected with military engineering, such as siege operations, field works, mines, bridging, &c.

The headquarters and depôt of the Royal Engineers are at Chatham, where their great instructional institutions are established. The distribution of the force depends on the works in progress in different parts of the empire. A considerable number of officers are stationed in India, but no men. Thirteen companies are now stationed abroad in our colonies and foreign garrisons—Bermuda, Gibraltar, Malta, &c.; and 27 companies, with the three troops of engineer train, are at home. Two companies are employed, under the direction of the Post-Office, in the construction and maintenance of the telegraph lines throughout the country, thus acquiring in peace time the practical experience necessary to enable them to undertake the working of telegraphic communications in war and in an enemy's country; and four are permanently engaged on the great ordnance survey of the kingdom. The others are distributed throughout the principal garrisons; eight or ten usually remaining with the headquarters at Chatham.

The duties of engineer officers are very various. Besides the actual command and superintendence of their men, and their instruction in all branches of field engineering, they include the charge, construction, and repair of fortifications and barracks, the survey of the kingdom, the management of a number of scientific and experimental establishments, the development of all the scientific appliances of war, such as armour plating, torpedoes, field telegraphy and signalling, &c., Engineer officers are also largely employed under the civil government in connection with the educational departments, railways, prisons, &c.

Infantry.

The infantry consists of 3 regiments of Foot Guards (7 battalions), 109 of the Line (137 battalions) and the Rifle Brigade (4 battalions,)—total, 148 battalions.

The three regiments of guards are the Grenadier Guards, of 3 battalions; and the Coldstream and Scots Fusilier Guards, of 2 battalions each. These form together the brigade of foot guards. They are stationed principally in London, and rarely leave the country except for active service in the field; they furnish the guards on the royal palaces, and guards of honour on state occasions, receive a special rate of pay, and have certain privileges. Up to 1872 their lieutenants had the rank of captains in the army, and their captains that of lieutenant-colonels. This privilege, however, was abolished by a warrant of July of that year as regards officers entering subsequent to that date.

Of the line regiments, Nos. 1 to 25 have two battalions each, two rifle regiments (the 60th and Rifle Brigade) have four each, and the remainder one only. By the localisation of 1873, the single battalion regiments have been grouped in pairs to form "district brigades." The several battalions are altogether independent of one another in matters of command, internal economy, &c.; but recruiting is carried on for the brigade, and men or officers may be transferred from one battalion to another within it. A district brigade comprises two line battalions, a brigade depôt, and a certain proportion of reserve and auxiliary forces.

A battalion of infantry consists of eight companies. Its war establishment is 1 lieutenant-colonel, 2 majors, 8 captains, 16 lieutenants and sub-lieutenants, 1 adjutant, 1 paymaster, 1 quartermaster, 1 assistant-surgeon, 10 staff sergeants, 8 colour sergeants, 32 sergeants, 16 drummers, 40 corporals, 4 hospital orderlies, 10 pioneers, and 946 privates,—in all, 31 officers and 1066 non-commissioned officers and men. On service it takes with it 62 horses (of which 9 are officers' chargers and 53 draught horses), and 14 waggons and carts (3 ammunition carts, 1 entrenching tool waggon, 1 for quartermaster's stores, and 9 for camp equipment and baggage) The peace establishment varies. Most of the battalions at home are kept at a reduced establishment of 520 rank and file, the guards at 750, the battalions next for foreign service at from 700 to 820, and the battalions in India at 820.

The infantry is at present armed partly with the Snider (converted Enfield) rifle, and partly with the Martini-Henry, but will ultimately be armed entirely with the latter. This weapon, which was selected in 1870 after a careful and protracted series of trials, is a breech-loading rifle, 4 feet 1 inch long, weighs 8 ℔. 12 oz., and ranges up to 1000 yards. It is seven-grooved, bore ·451 of an inch, carries a bullet weighing 1 oz., and has been fired at the rate of 25 rounds a minute. The soldier carries 70 rounds of ammunition, viz., 20 in each of two pouches on the waist belt, 10 in expense bag, and 20 in a pocket in his valise. The bayonet (Elcho sword-bayonet) is a short heavy sword, with saw-back, which can be attached to the rifle as a bayonet, or used independently as a sword, or to cut up firewood, chop bushes, &c.

Although the regiments are named Rifles, Fusiliers, Light Infantry, &c., the organisation, armament, and training is the same throughout, the only distinction being in matters of dress. The two rifle regiments wear dark green; all the rest of the infantry wear red. The guards are distinguished by their tall bearskins; the fusilier regiments (9) wear sealskin caps, resembling the bearskins of the guards, but smaller. There are 9 Highland regiments, of whom 5 wear the kilt and bonnet; the others have minor distinctions in dress. The light infantry regiments, 11 in number, are distinguished by a horse-hair plume to the shako in place of a ball. The "facings" vary with the different regiments, but all "royal" regiments have blue.

All regiments now carry the valise equipment, substituted for the knapsack in 1870. It consists of a black leather bag slung from the shoulders by straps and fitted to lie in the hollow of the back, connected with a waist-belt and ammunition-pouches in such a manner as to distribute the weight evenly over the body, and cause it to hang direct on the shoulders. The greatcoat, when not worn, is strapped above it. The valise holds a spare shirt, pair of boots, socks, cap, towel, and other small articles, and when full weighs about 15 ℔; the total weight carried by the soldier, including arms, ammunition, and the clothes he has on, amounts to about 52 ℔.

Each battalion has four hospital orderlies, picked men specially trained to the care of sick and wounded, and relieved from all other duties; and ten pioneers, skilled artificers of various trades, who carry a complete set of carpenters' and other tools, and are employed, sometimes under the quartermaster of the regiment and sometimes under the engineers, in executing repairs and other works.

The guards and rifle regiments recruit through the country generally: the former maintain a high standard, usually 2 or 3 inches above that of the line; the latter take men of low standard, but require special chest measurement. The other infantry regiments recruit as far as possible within the brigade districts in which the depots are permanently stationed. Of the 141 line battalions, 50 are stationed in India, 20 in the colonies and foreign garrisons, and 71 at home; thus allowing one battalion at home and one abroad from each brigade. The chief foreign garrisons are Malta (7 battalions) and Gibraltar (5 battalions). The largest home stations for infantry are London (for the Guards), Portsmouth, Dublin, Cork, Plymouth, Chatham, Dover, and the camps of Aldershott, Colchester, Shorncliffe, and the Curragh.

The oldest infantry regiments are the Coldstream Guards (General Monck's regiment), the 1st "Royal Scots" (originally the "Douglas" regiment), the Grenadier and Scots Fusilier Guards, the 2d "Queen's" (raised for the defence of Tangier), and the 3d "Buffs" (raised from the London train-bands). These regiments were formed between 1660 and 1662. The principal augmentations made to the army between this date and the Crimean war have been already detailed. Second battalions were added to the regiments from 1 to 25 in 1857–59, and the 100th was raised in Canada in 1858. The nine regiments from 101 to 109 were formed from the European regiments in the service of the East India Company, on the transference of the powers of that company to the Crown.

Reserves and Auxiliary Forces.

The reserves are divided into classes. The "1st Class Army Reserve" consists—(*a*) of men who, after a service of not less than three years in the ranks of the army, have been passed into the reserve to complete the unexpired portion of their engagement; and (*b*) of soldiers who have been discharged by purchase or on completion of limited engagement, and have enrolled themselves for 5 years. The men of the 1st class reserve receive 4d. a-day, paid quarterly in advance, and an annual allowance of £1 for necessaries. In peace time they may be called out for 12 days' training annually, or to aid the civil power, receiving daily pay at the rate of 2s. in the first case, and 2s. 6d. in the second. In case of war or national danger, they may be recalled to service by proclamation, and attached to any regiment or corps of their own branch of the service, or formed into separate corps. They then resume their position in all respects as soldiers of the regular army, and are liable for service at home or abroad, and until completion of their term of engagement. The 2d class army reserve consists of enrolled pensioners,—men who have completed their second period of service in the regular army, and been discharged to pension. They receive no bounty, but an annual allowance of £1 for necessaries, and daily pay at the rate of 2s. or 2s. 6d. when called out for training or in aid of the civil power. They are subject to the same regulations as the 1st class, except that they are only liable for service within the United Kingdom.

By the Act of 1867, a *militia reserve* was created in addition to the above, consisting of men actually serving in the militia who voluntarily enrol in this reserve for a term of six years, during which they remain with their militia regiments in peace time, but in case of war may be drafted into the regular army. They receive an annual bounty of £1 in addition to their militia pay and bounty. Their number is limited to one-fourth of the effective strength of the militia, and in 1873 amounted to 28,286 men.

The first attempt to organise a reserve of men who had passed through the ranks of the army was made in 1843, when the enrolment of pensioners for home service in special cases was authorised by Parliament. The number was originally limited to 10,000, but afterwards increased to 20,000. In 1859 when the military power and threatening attitude of France caused the alarm in England which led to the volunteer movement, an effort was made to organise a more efficient reserve from men who had taken their discharges on completion of their first period of service, but the inducements offered were insufficient, and the scheme proved a failure. In 1867, after the proved success of the short service and reserve system in Prussia, a new Reserve Force Act was passed, which, with subsequent modifications, laid the foundation of the present first-class reserve; but it required increased inducements, and the Short Service Act of 1870, to give the reserve any importance. The militia reserve was formed as a temporary expedient, to be reduced as the army reserve increases. It has been objected to on the grounds that it entails increased expense without any real addition to the armed force of the country, as the men are merely passed from one force to another, and that it takes away the best men from the militia at the moment this requires to be most efficient. But, in the absence of a sufficient reserve of fully-trained soldiers, a reserve of partly trained men is essential. Practically the militia always has been the feeder of the line in war time, and it was thought better to enrol a number of men in peace time, when they could be selected, and all necessary preparations made for drafting them in at once in war, rather than adhere to the old system of offering high bounties at the last moment, and getting a worse class of men.

For auxiliary forces, MILITIA, YEOMANRY, and VOLUNTEERS, see separate articles.

Local Organisation of the Military Forces of the Kingdom.

The United Kingdom is divided into 10 military districts, or general officers' commands,—viz., England, 6; Scotland, 1; Ireland, 3.[1] Within the district the general officer's authority extends over all the military forces—regular, reserve, or auxiliary. These districts, again, are subdivided into 66 infantry brigade or sub-districts under colonels; of these 50 are in England, 8 in Ireland, and 8 in Scotland. Each brigade comprises 2 battalions of the line, a brigade depôt, 2 militia battalions, and such reserves and volunteers as are included in the sub-district; the average male population of the sub-districts being 200,000. The two line battalions are independent of the colonel of the sub-district. One is always abroad, one at some home station, usually a garrison or camp of instruction. But they draw their recruits and reserves from the sub-district, and supply the officers and non-commissioned officers for the brigade depôt, and for the staff of the militia and volunteers. The brigade depôt is the connecting link between the line battalions and the district. It is permanently established at some principal town in the sub-district, and is formed of two companies from each line battalion, under the command of a major of the home battalions. To it are attached 2 captains (adjutants of militia battalions) and a large staff of non-commissioned officers, who join the militia battalions when embodied, but at other times are employed at the depôt in recruiting and drilling recruits. The duties of the colonel of the district include recruiting for the line and militia, the training of recruits and of all reserve and auxiliary forces, the annual inspection of the militia and volunteers, the registry and payment of the army reserve and enrolled pensioners, and the care of arms and stores of reserve and auxiliary forces.

For cavalry purposes Great Britain is divided into 2, and for artillery into 12 sub-districts, under colonels, whose duties correspond in the main with those of the infantry colonels as regards recruiting and supervising the training of the auxiliary forces of their respective arms, but are more restricted, as they have no depôts and staff of regulars under their immediate command.

The colonel of the brigade depôt is especially charged with the measures for mobilisation in case of war. On the order being given, the army reserve and militia reserve men are collected at the depôt, and sent to the home battalion to complete it to war strength. The supernumerary men of the reserve, and all men of the field battalion that are unfit for immediate service, are drafted to the depôt, which is increased to the strength of an eight-company battalion, by calling in officers from the half-pay list, and by recruiting. At the same time, one, or, if necessary, both militia battalions are embodied. If an expeditionary force is to be despatched, the militia battalions relieve the regular army in all the home garrisons; and probably, as was the case during the Crimean war, in some of the foreign ones also.

Civil Departments of the Army.—Control Department.

The Control Department was formed in 1869 and 1870 by the amalgamation of the five formerly distinct administrative departments, viz., Commissariat department, Barrack

[1] This is exclusive of the four military stations or camps of Aldershott, Woolwich, Chatham, and the Curragh, to which no districts are attached.

department, Store department, Purveyors' department, and Military Train. At the head of the Control Department is the Surveyor-General of Ordnance, assisted by a director of supplies and transport, and a director of artillery and stores; the general duties of the department have already been defined in treating of the administration of the army.

The *personnel* of the Control Department consists of—(*a*), administrative officers, named controllers; (*b*), executive officers, divided into two sub-departments, and named commissaries and paymasters; (*c*), the non-commissioned officers and men of the Army Service Corps. The ranks of *administrative officers* are—controller, ranking with major-general; deputy-controller, ranking with colonel; and assistant-controller, ranking with lieutenant-colonel. Appointments as assistant-controller are made from commissaries in the supply and transport sub-department, or from combatant officers of the army. In the latter case the officers selected must have five years' full-pay service, be not under the rank of captain, not over 35 years of age (40, if belonging to the artillery,) and have passed through the Staff College or the advanced class at Woolwich. They serve on probation for two years, at the end of which, if found competent and willing to serve in the Control Department, they resign their military commissions, and receive commissions as assistant-controllers. Artillery officers are generally selected to fill the appointments in the artillery and store branch, but the great majority of appointments are made from the sub-departments, and but few from the combatant ranks of the army. Promotion to the higher grades is by selection, after a service of not less than ten years for the rank of deputy-controller, and thirteen years for that of controller, at least three years having been in the next lower rank. After thirty years' full-pay service, Control officers are entitled to retire; and retirement is compulsory at the age of 60.

Officers of the Control Department conduct their duties under the direct orders of the officer commanding the district or station, whose advisers and agents they are in all matters connected with the raising or issue of money, the supply of provisions, stores, and transport. They hold a position analogous to that of officers of the general staff, except that they are at the same time directly responsible to the Secretary of State for War for the proper conduct of their duties. Where the orders of the officer commanding appear inconsistent with the War Office instructions, it is the duty of the Control officer to point out the inconsistency, and apply for special authority from the commanding officer, which being granted, must be implicitly obeyed, and relieve the Control officer from the responsibility.

The *executive sub-departments* are the supply and transport sub-departments, and the pay sub-department. The ranks in the former are—commissaries, ranking with majors; deputy-commissaries, ranking with captains; and assistant-commissaries, ranking with lieutenants. The ranks are the same in the pay sub-department; but the officers are called paymasters instead of commissaries. First appointments in the supply and transport sub-department are conferred on civilians selected by open competitive examination, or subaltern officers of the army, and on deserving non-commissioned officers; the limit of age is 17 to 20 for civilian candidates, and 22 for subalterns of the army or militia. Retirement may be claimed after thirty years' service, and is compulsory at the age of 55.

The *Army Service Corps* consists of 12 transport companies and 11 supply companies, officered from the supply and transport sub-department. The establishment of a supply company is 2 officers, 27 non-commissioned officers, and 97 rank and file; of a transport company, 3 officers, 13 non-commissioned officers and 117 rank and file, with 91 horses and 26 carriages. In war time these would be largely augmented, according to the requirements of the army and the nature of the service. The supply companies consist of butchers, bakers, issuers, clerks, mechanics and tradesmen of various kinds; the transport companies of drivers, with a proportion of smiths, wheelers, saddlers, farriers, &c. The ranks of the Army Service Corps are filled by volunteers from the army,—men of good character, specially recommended, and of not less than two years' service,—or by recruits specially enlisted for it under authority from the Secretary for War. The rates of pay are nearly the same as in the cavalry, but the artificers and tradesmen usually earn working pay in addition. The uniform is blue. The supply companies are armed with breech-loading carbines and sword bayonets, the transport companies with cavalry swords.

The executive duties that devolve on the Control may be classed broadly under four heads—pay, provisions ("*munitions de bouche*"), stores ("*munitions de guerre*"), and transport; and officers of the sub-departments are selected as far as possible for service in the several branches according to their special training. The provision branch is the most important, and occupies the largest number of officers. In peace time the soldier is fed partly by the Control, partly by means of purchases made by himself. He receives a free ration from Government of 1 ℔ of bread and ¾℔ of meat, and in addition expends a sum varying from 3½d. to 6d. a day on groceries, vegetables, &c. Under certain circumstances the Government ration is slightly increased, and in the field it is raised to 1½ ℔ bread and 1 ℔ meat; and rations of groceries, spirits, and vegetables are also provided by the Control, though paid for by the soldier. The forage ration for a horse is 10 ℔ oats and 12 ℔ hay, with 2 ℔ extra oats to horses picketed out, and 2 ℔ oats and 2 ℔ hay additional to draught horses doing very heavy work. In peace time the army is supplied by contract, the contractor usually delivering the bread and meat or forage at the Control store, where it is inspected by a board of officers before issue. At some of the large camps and stations, however, ovens and slaughter-houses have been established, at which the bread is baked and the meat killed and prepared for the troops by the men of the Army Service Corps. When troops are encamped on flying columns, or for autumn manœuvres, iron field-ovens or steam baking waggons are commonly used; the former turning out about 480 ℔ of bread in a day of 12 hours, the latter about 900 ℔. Biscuit and salt meat are largely used abroad and at sea, but not at home. (For the supply of an army in the field, see article WAR.)

The *transport* duties of the army in peace time, when all the civil resources of the country are available, and most articles are delivered at the required point by the contractor, are very slight; but to be efficiently organised for the field, an army requires a vast amount of transport, of which the existing establishment would only suffice to form the nucleus. The British army is differently situated from the great Continental armies in this respect, that its operations extend over the most distant and varied countries, involving the most different conditions; and as the transport service must always be specially organised to suit the peculiar conditions of the theatre of war, it is impossible in peace time to maintain an establishment which shall be equally applicable in all cases. In some countries railways and water transport are largely available, and the duties thrown on the train are comparatively light; in other countries the local resources in carts and waggons, if properly organised, are ample, and a sufficient *cadre* of officers and superintendents is alone required; in others, again, the local resources are *nil*, and the army has to bring with it every man, horse, and waggon of the vast train it requires.

And the character of the transport varies as widely as the quantity required. In some countries large waggons are most suitable, in others, light carts only can be used; in others, again, recourse must be had to pack animals,—horses, mules, bullocks, camels, and elephants,—or to coolies and native carriers. Evidently no establishment can be framed that shall be equally suitable in all cases. The existing transport, therefore, is based on the requirements of an army operating in a civilised country, with good roads, where the transport can be mainly done by waggons; while for special expeditions, such as those to Abyssinia and Ashantee, special transport is organised. The waggon in common use is the "general service waggon," a strong four-wheeled (equirotal) waggon, drawn by four horses, weighing 16 cwt., and carrying a load of 30 cwt.

The transport companies at the disposal of the Control have to carry the equipment and baggage of the staff and departments, to horse and drive the ambulance and field hospital waggons, and, above all, to carry the supplies and reserve stores of the army, the bringing the daily supplies to the troops being the duty which taxes them most heavily.

The charge and issue of warlike stores is a duty of ever-increasing importance and difficulty in these days of scientific warfare. In most armies this duty devolves on the officers of the artillery, whose education specially qualifies them for it, and the question was warmly discussed when the Control Department was formed. It was ultimately decided to unite all supply duties under the Control, providing, however, by an admixture of artillery officers for the necessary scientific knowledge within the department.

The following table shows the establishment of officers of the Control Department in 1873, with their full pay, and the daily rates of half and retired pay to which they become entitled:—

Nos. (on Full Pay.)	Rank.	Full Pay.	Half Pay.	Retired Pay, after 30 years' service.
3	Controllers	£3 0 0	£1 10 0	£2 0 0
14	Deputy-Controllers*	2 0 0	1 1 0	1 13 0
40	Assistant-Controllers*	1 4 0	0 13 6	1 0 0
53	Commissaries*	0 18 6	0 10 0	0 16 8
135	Deputy-Commissaries*	0 11 6	0 7 0	0 11 8
142	Assistant-Commissaries*	0 9 0	0 4 6	0 7 8
12	Paymasters*	1 0 0	0 12 6	1 0 0
20	Deputy-Paymasters*	0 14 6	0 8 3	0 14 0
36	Assistant-Paymasters*	0 10 6	0 5 3	0 9 0
455, of whom 116 were abroad and 339 at home.				

Note.—In the ranks marked thus * the full pay is increased after five years' service in the rank by amounts varying from 2s. 6d. to 5s. daily. A reduced rate of retiring pay is allowed to officers of over twenty but less than thirty years' service, who are permitted to retire. In addition to the numbers shown above, 40 sub-assistant commissaries are appointed, on probation, at a rate of 6s. 6d. per day.

Medical Department.—Hospitals.

The Medical Department comprises 4 ranks of medical officers—viz., Surgeon-General, Deputy-Surgeon-General, Surgeon-Major, and Surgeon,—and the officers and men of the Army Hospital Corps; the whole being under a director-general at the War Office. The officers of the two higher grades are employed chiefly as administrative officers superintending districts or large hospitals; while the surgeons-major and surgeons are attached to regiments and corps, or employed as executive officers in the hospitals. Every battalion serving at home or in the colonies has one medical officer attached to it; and every battalion in India has one surgeon-major and two surgeons. First appointments in the Army Medical Department are given to candidates who possess two diplomas or licences for medicine and surgery, and, after attending a probationary course at a general military hospital, pass a satisfactory examination in military medicine, surgery, hygiene, and pathology. On appointment as surgeons they rank as lieutenants, and after 6 years' full-pay service, as captains. Promotion from surgeon to surgeon-major is by seniority, but officers may be specially promoted for distinguished service. Surgeons-major rank as majors on appointment, and after 20 years' full-pay service (in the two ranks), as lieutenant-colonels. Promotion from surgeon-major to deputy-surgeon-general, and from that to surgeon-general, is by selection of the Commander-in-Chief, with approval of the Secretary for War. Deputy-surgeons-general rank as lieutenant-colonels from the date of appointment, and after 5 years' service in the rank as colonels; and surgeons-general as brigadiers for three years, and afterwards as major-generals. The establishment and rates of pay of the several ranks are shown in the following table:—

No.	Rank.	Daily Pay.
		£ s. d. — £ s. d.
10	Surgeons-General	2 0 0 rising to 2 10 0
33	Deputy-Surgeons-General	1 10 0 ,, 1 17 0
439	Surgeons-Major	0 17 6 ,, 1 7 0
625	Surgeons	0 10 0 ,, 0 15 0
1107, of whom 476 are employed at home, 130 in the colonies, and 501 in India.		

All officers have a right to retire on half-pay after 20 years' service. Surgeons and surgeons-major must retire at the age of 55, and surgeons-general and deputy ditto at the age of 65. Officers retiring after 20 years' service receive a rate equal to half their full pay at the time; after 25 years' full-pay service, a rate equal to seven-tenths of full pay.

The *Army Hospital Corps* consists of 11 "captains of orderlies," 10 lieutenants, 264 sergeants-major and sergeants, and 1060 rank and file. They are employed entirely on hospital duties, and are under the direction and control of the medical officer of the station, though subject for discipline to the military authority. The officers and non-commissioned officers rank with the corresponding grades in the army, but their authority is confined to their own men and to patients and men attached to military hospitals on duty. Appointments of officers are made from the non-commissioned officers of the corps: the ranks of the corps are filled by volunteers from the army,—men of good character, able to read and write, of not less than two years' service, and not over 30 years of age; and by recruits, whose direct enlistment is specially authorised. They are variously employed as clerks, compounders of medicines, cooks, &c., but principally as attendants on the sick in the general hospitals in peace, or in field hospitals and ambulances in war.

Hospitals are either "general" or "station" hospitals: to the former special governors or commandants are appointed; in the latter the internal administration is under the senior medical officer. The Royal Victoria Hospital at Netley, whither all invalids from abroad are sent, is the largest *General Hospital;* it has a large staff, a medical school, and accommodation for 973 patients.

Station Hospitals are organised at all large military stations, for the sick of all regiments or corps quartered there. The hospital is under the immediate supervision of the principal medical officer, usually a deputy-surgeon-general, and all medical officers at the station are available for such general service in it as he may direct; but separate wards are allotted to the different regiments and corps, and their sick are kept as far as possible distinct, and under the immediate attendance of their own medical officers and orderlies. The hospital staff consists of the medical officers attached to regiments at the station, a certain number of medical officers specially attached to the hospital, the officers and men of the Army Hospital Corps, and the hospital sergeants and orderlies of the regiments at the station. At small stations a building or block is specially fitted as a hospital, and is under the charge of the medical officer of the regiment or corps. When an army is organised for service in the field, *field hospitals* and *ambulances* are formed. The latter consist of a number of ambulance waggons, light waggons specially constructed for the carriage of sick and wounded, with a sufficient staff of medical officers and attendants, and a company of "stretcher bearers," provided with stretchers; these are charged with the immediate removal of the wounded from the battle-field, their first dressings, and conveyance to the nearest field hospital. The field hospitals are provided with large hospital tents, beds, and all the requirements of an hospital, and a sufficient staff of medical officers and attendants, and either accompany the army in its march, or establish themselves in suitable places in rear. The ambulance waggon commonly used is four-wheeled, weighing 16 cwt., drawn by two horses, and constructed to carry eight wounded (two lying down and six sitting), besides a water keg, stretchers, and other medical appliances.

For care of sick and wounded in war, see article WAR.

The general health of the army has greatly improved of late. The disasters of the Crimean war first drew attention to the importance of proper sanitary arrangements in the field; but what, perhaps, aroused public attention still more strongly was the report of the Royal Commission of 1858, by which it appeared that the mortality in the army generally was twice as great, and in the foot guards three times as great, as in the corresponding classes of the civil population. Since then, improved barracks, better meals, gymnasia, recreation-rooms, and out-of-door amusements provided for the soldier, have reduced the death-rate to one-half; while the Contagious Diseases Act, severely attacked as it has been, has materially lowered the sick-rate at those stations where it is in force. The admissions from causes under its control have, within five years, been reduced to less than a third at some of the large stations; while a comparison of 14 stations at which the Act is in force, with 14 to which it has not been extended, shows 54·5 cases per 1000 men at the former, and 113·3 at the latter. The annual death-rate in the army generally averages about 14 per 1000. In 1870 Gibraltar, Malta, and Canada were the healthiest stations, showing a death-rate of only 8·7 per 1000. The United Kingdom came next, with a rate of 9·5; while in India the death-rate rose to 22·8. But to appreciate the improvement that has been effected in the health of the army, it is necessary to turn back to the fifteen years preceding the Crimean war, when the death-rate in the United Kingdom averaged 17·5, and that of the army generally 33 per 1000; while the death-rate in India averaged 62 per 1000 between 1837 and 1853, and 81 per 1000 in the twenty years preceding 1837

Veterinary Department.

The Veterinary Department is charged with the supervision of the sanitary condition of horses, and their treatment when sick; also the selection of such as are proposed to be cast as unfit for the service, and the examination of remounts. The grades are—staff veterinary surgeons, ranking as majors; veterinary surgeons, 1st class ranking as captains, and 2d class ranking as lieutenants; the whole under a principal veterinary surgeon, who ranks as a colonel. Candidates for appointment are required to pass an examination before a board of veterinary surgeons. Veterinary surgeons of the 2d class must have served five years, and passed a further examination, to be promoted to the 1st class; and a service of fifteen years is required for promotion to staff veterinary surgeons. All officers of the department are entitled to retire on half-pay after twenty-five years' service, and are placed on the retired list at the age of 55. The establishment (1873) and rates of daily pay of the several ranks are as follows:—

7	Staff Veterinary Surgeons........	£1	1	0	rising to	£1	3	0
35	Veterinary Surgeons, 1st class...	0	12	6	,,	1	0	0
70	,, ,, 2d class...	0	10	0	,,	0	17	6
112								

A limited number of acting veterinary surgeons are employed at the discretion of the Secretary for War.

Staff veterinary surgeons are employed to supervise districts or great military stations, the others are attached to cavalry regiments, horse and field artillery, &c. The uniform of the staff surgeons is blue, similar to that of officers of hussars, but with cocked hat and red plume; the veterinary surgeons attached to regiments wear the uniform of the corps, with cocked hat and red plume.

Chaplain's Department.

The Chaplain's Department is under the Chaplain-General at the War Office. Chaplains to the forces are appointed by the Secretary for War; they must previously be in holy orders, and belong either to the Church of England or Ireland, to the Presbyterian, or to the Roman Catholic Church, and must serve six months on probation before their appointment is confirmed. They are divided into four classes,—the first ranking as colonels, the second as lieutenant-colonels, the third as majors, and the fourth as captains. Promotion is governed by length of service, —chaplains being promoted to the third class after ten years, to the second after fifteen years, and to the first after twenty years; but for distinguished services any chaplain may be promoted to the next higher class without regard to length of service. Chaplains are entitled to retirement after twenty-five years' service. The establishment (1873) and rates of daily pay of the several classes are as follows:—

10	Chaplains, 1st class............	£1	0	0	rising to	£1	2	6
20	,, 2d class	0	17	6				
30	,, 3d class	0	15	0				
20	,, 4th class	0	10	0	,,	0	12	6
80								

Of these, fifteen are Roman Catholics and six Presbyterian. Chaplains are not attached to particular regiments or corps, but are stationed at the principal garrisons and military stations at home and abroad. Garrison chapels, used also in many cases as schools, exist at all the large stations. At smaller stations the troops attend divine service at the parish churches, and an allowance is made to a local clergyman for attending the troops, performing special services when necessary, and visiting the sick.

Education Department.

The educational establishments for the army consist of the military colleges, a staff of instructors for officers serving with their regiments, and army or regimental schools for the instruction of the non-commissioned officers and privates of the army and their children. The supervision of the education of the army rests with the Director-General of Military Education at the War Office.

Military Colleges.—The *Staff College* was established in 1858, with a view to train officers for employment on the staff of the army; replacing the "senior department" of the Royal Military College at Sandhurst, which had existed since the beginning of the century. The present building, near Sandhurst, was completed in 1862, and accommodates forty students. The qualifications and manner of admission of students have already been noticed (under "Staff"). The course lasts two years, beginning in February, and with vacations at Christmas and Midsummer. The subjects of instruction are military history and art, fortification, military administration and law, surveying and sketching, reconnaissance, mathematics (including a short course in mechanics and practical astronomy), sciences, and languages; a large part of the course being devoted to out-of-door work and practical instruction in the duties of staff officers in the field. The Staff College is open to officers of all arms of the service, and twenty students are admitted each year. At the end of the first year they are required to pass a qualifying examination; and at the end of the second, the final examination is held, at the close of which the names of the successful candidates are published in general orders, divided into two classes,—"Honours" and "Pass." Those officers who fail at the qualifying or at the final examination rejoin their regiments at once. The staff of the establishment consists of a commandant and ten professors, of whom four are military, the others civilians.

The Royal Military College, Sandhurst, was originated in 1786, and in 1801 was transferred from Marlow to its present site, and officially recognised by Parliament. This institution was formerly devoted to preparing young gentlemen for commissions in the infantry and cavalry, the ages of admission varying from thirteen to sixteen and eighteen at different periods. Now it is devoted to the instruction of young officers of these arms after they have passed the requisite examination for commissions, and before they are appointed to regiments. The course lasts a year, and the instruction is confined altogether to purely military subjects,—fortification, military sketching, tactics, military law, correspondence, and accounts. At the conclusion of the course the students are required to pass an examination in these subjects, and their commissions are dated according to the result,—those in the first class being antedated two years; those in the second, twelve months; and those in the third dating from day of examination. The present building accommodates about 150 students, and it will probably be necessary to increase it considerably. The staff of the establishment consists of a governor, with an assistant and five staff officers (paymaster, surgeon, &c.), and twelve military professors and instructors. A riding establishment and master are also kept up for the instruction of the students both of the Royal Military College and of the Staff College.

The Royal Military Academy at Woolwich was first established in 1741, and is devoted to the training of candidates for commissions in the artillery and engineers. The course of instruction, which lasts for three years, is mainly scientific and professional, mathematics playing an important part in it. The students are finally classed by the results of the examination held at the end of the course, those who pass the highest having the option of appointment to the engineers, and seniority in the army being determined by their position on the list. The present building accommodates about 250 students. The staff consists of a governor, with a secretary and adjutant, a "captain of cadets" and three "lieutenants of cadets" for purposes of discipline, and twenty-one professors and instructors.

Garrison Instructors.—For the instruction of officers serving with their regiments, and to enable them to qualify in the special examinations for promotion, staff officers, with the title of garrison instructors, are appointed to all the principal garrisons and military stations at home and abroad. Classes under these are formed for instruction in tactics, field fortification, military sketching and reconnaissance, and law. The course of instruction usually lasts four months, during which time the officer is struck off all other duties. At the close of the course an examination is held, and those who pass satisfactorily are certified as qualified for promotion. Garrison instructors hold the rank and receive the staff pay and allowances of brigade-majors, and are selected from officers who have passed through the Staff College. The establishment consists of one superintending officer (with rank and pay of assistant quartermaster-general) and seventeen garrison instructors, stationed at home or in the foreign garrisons on the British establishment, and one superintending officer and ten garrison instructors in India.

Army Schools are established in every regiment and detachment, for the purpose of giving to non-commissioned officers and soldiers, and to their children, a sound and useful education. These schools are divided into adult, grown children, infant, and industrial schools. To every regiment are appointed a schoolmaster and schoolmistress, and a certain number of assistant schoolmasters, pupil teachers, and monitresses, on a scale according to the number of men and children attending school. Batteries of artillery and detachments of other corps are allowed an acting schoolmaster, with such assistants as may be necessary. All soldiers, soldiers' children, and children of men belonging to the army reserve, of warders of military prisons, and of discharged soldiers holding military employments, are admitted free of charge to these schools; and children of pensioners and others indirectly connected with the army, on a weekly payment of 3d. Recruits, on first joining, are required to attend these schools; and soldiers who are candidates for promotion must obtain certificates of proficiency before they are eligible. Advanced classes are also formed for the instruction of non-commissioned officers. Army schoolmasters receive a rate of pay varying, according to service, from 4s. a-day on appointment to a maximum of 7s. a-day, and rank as non-commissioned officers next below the sergeant-major. Candidates are required to go through a course in the training schools of the Royal Military Asylum, Chelsea, admission to which is by competitive examination, open to non-commissioned officers and soldiers of the army (of good character and especially recommended), to civilian pupil teachers, and certificated schoolmasters. Before appointment the candidate must enlist for general service for twelve years.

Schoolmistresses are classed in three classes, receiving from £30 to £44 yearly. Candidates must be certificated schoolmistresses, or have been employed as teachers in an army school, and in the latter case must pass an examination before appointment. All first appointments are made to the third class, and promotions are made according to merit and services.

At all important military stations and garrisons large and commodious schoolhouses have been specially built; at smaller stations barrack-rooms are told off and fitted up for the purpose. Schoolmasters and mistresses are permanently attached to regiments, and accompany them from station to station, and the schools are under the immediate and constant supervision of the commanding officer. They are also periodically visited and examined by inspectors, who report to the director-general, for which purpose a staff of one inspector of army schools, two local inspectors (officers of the army, receiving an additional rate of pay for performing these duties), and twelve sub-inspectors, are maintained. The improvement that has taken place in the education of the army generally may be gathered from the reports and returns of the director-general, by which in appears that between the years 1858 and 1871 the proportion of "uneducated" fell from 40 per cent. to 12 per cent., and that within the last few years the number possessing a superior education has risen from 6 to 32 per cent. And although much of this is doubtless due to the spread of education throughout the country, a comparison of the educational statistics of the recruits with those of the army generally proves that still more is due to the regimental schools.

Garrison Libraries and *Regimental Recreation-Rooms* have also been established at the principal barracks at home and abroad, and are open to the troops on payment of a small subscription, which must not exceed threepence a month for a private soldier. The garrison library forms a central depôt from which the recreation-rooms are supplied with books. All the rooms are furnished, warmed, and lighted at the public expense, and the recreation-rooms provided with billiard and bagatelle tables, chess, backgammon, and other games. An annual allowance of £2, 10s. is granted by Government for each troop or company; this, with the subscriptions, forms a fund to defray the cost of purchase and repair of books in garrison libraries, and of games, newspapers, &c., for recreation-rooms. Many recreation-rooms have a refreshment bar attached to them, where the men are supplied with tea, coffee, and other light refreshments at a very low price. A garrison librarian, usually a non-commissioned officer or a pensioner, takes charge of the library, and a regimental librarian has charge of the recreation-rooms. These are managed by a committee composed of non-commissioned officers and privates; and the garrison libraries are managed by a committee consisting of members chosen from the regimental committees, under the approval of the officer commanding the station.

Scientific and Educational Establishments.

The *Department of Artillery Studies* was established to give officers of the artillery the means of continuing their studies after they have completed the regular course at Woolwich, and of qualifying by a special training for appointments requiring exceptional scientific attainments. The establishment consists of a director, an assistant-director, and two instructors of artillery, and a number of instructors and lecturers for mathematics, languages, and sciences. Its duties include the instruction of an advanced class of artillery officers, selected by competition, to qualify for scientific appointments; and the formation of classes in topography, astronomy, and languages, open to all officers of the artillery wishing to join them. A *School of Gunnery* is maintained at Shoeburyness for the purpose of giving practical instruction in gunnery to officers and men of the artillery, and carrying on all experiments connected with artillery and stores. The present site was selected for the school in consequence of the facilities afforded by the sands at the mouth of the Thames for artillery practice and firing at long ranges. The establishment consists of a commandant and brigade-major, with six instructors for the gunnery department; and two superintendents of experiments. Officers and non-commissioned officers are selected from brigades of artillery to go through a long course of instruction in gunnery, use of military machines, &c., and qualify as instructors to brigades and batteries; and squads of officers and men are sent there for instruction in the various branches of artillery service.

The *Royal Artillery Institution* at Woolwich was originally a private military society, but the present building was erected at Government expense, and the institution is now supported partly by the subscriptions of members, partly by a Government grant. It contains a museum, lecture theatre, laboratory, and a printing-press; and minutes of proceedings, containing papers on professional and scientific subjects, are periodically issued from it.

The *School of Military Engineering* at Chatham constitutes a special training school for officers of the Royal Engineers after they have passed through the course at Woolwich, as well as for recruits on first enlistment. Companies are also sent there previous to going abroad, and on return from foreign service, to keep up their knowledge. The establishment consists of a commandant and brigade-major, two discipline officers, and eleven officer instructors in construction, surveying, field fortification, telegraphy, &c.

The *School of Musketry* at Hythe was established shortly after the introduction of rifled fire-arms, to give a special training in the theory and practice of musketry to officers and non-commissioned officers qualifying to act as musketry instructors to their regiments, and to secure a uniform system of instruction and practice throughout the army. With this view also, squads of officers and men from all regiments in the service are periodically sent there for a short course. The establishment consists of a commandant, a deputy assistant adjutant-general, and five officer instructors. The commandant is also inspector-general of musketry, and exercises a general supervision over the instruction and practice throughout the army; for which purpose periodical reports are made to him from all regiments, and the annual musketry returns are carefully examined by him before being submitted, with his remarks, to the Commander-in-Chief. To secure sufficient attention to this important part of a soldier's training, musketry instructors are appointed in every regiment; and staff officers, formerly termed district inspectors of musketry, are appointed to the principal districts. Every recruit is required to go through a course of instruction and practice before being dismissed drill, and every trained soldier is put through an annual course, lasting about a fortnight, in which he fires 60 rounds at fixed distances from 150 to 800 yards. Extra pay of 1d. a day is given to those men who qualify as "marksmen," and additional rewards to the best shots of companies and battalions.

An *Army Medical School* was formed in connection with the great military hospital at Netley, to which candidates for appointments as surgeons are sent for a probationary course. The school is under the immediate direction of the principal medical officer at Netley, and has a staff of nine professors and assistant professors of military surgery, medicine, hygiene, &c.

The *Military School of Music* at Kneller Hall, Hounslow, was established in 1857 with the view of instructing non-commissioned officers and soldiers in music, and supplying competent bandmasters and trained musicians to the various regiments. The staff consists of one officer and a number of civil professors: the students, limited to 148, are soldiers selected for good conduct and promise of musical proficiency, and remain for two years.

The *Royal Military Asylum* at Chelsea (also known as the Duke of York's School), and *Royal Hibernian Military School* at Dublin, are establishments for the maintenance and education of a limited number of boys who are the sons of soldiers. Candidates for admission must be between the ages of 5 and 12 years, and they are allowed to remain till 14, or, if they belong to the band, till 15. They are then allowed to volunteer into any regiment they may select, or, if not fit for the service, are apprenticed to a trade or placed in some other civil employment. The

Royal Military Asylum at Chelsea is also a normal school and training institution for army schoolmasters.

Administration of Justice—Judge-Advocate-General's Department—Military Prisons.

Justice is administered by the commissioned officers of the army: by the commanding officer for minor offences, and by regimental, district, or general courts-martial for more serious crimes. (See MILITARY LAW.). The administration of justice as pertaining to *discipline* falls under the Adjutant-General's branch of the department of the Commander-in-Chief. But to ensure these disciplinary powers being exercised in strict conformity with the law, a *Judge-Advocate-General*, a legal adviser to the Crown and to the Commander-in-Chief, is appointed by patent. This officer is usually a lawyer of high standing, having a seat in the House of Commons, holding his office as a member of the Government, and quitting office with his party. His department includes a deputy judge-advocate-general, who is also a lawyer and civilian, and three deputy judge-advocates, military officers; of the latter, two are attached to the Judge-Advocate-General's office in London, and one to the Commander-in-Chief in Ireland. A separate Judge-Advocate's department is maintained in India, where deputy judge-advocates are appointed to every important command. All general courts-martial held at home are sent to the Judge-Advocate-General, to be by him submitted to the Queen for confirmation; and all district courts-martial, after having been confirmed and promulgated, are sent to his office for examination and custody. The Judge-Advocate-General and his deputy, being judges in the last resort of the validity of the proceedings of courts-martial, take no part in their conduct; but the deputy judge-advocates frame and revise charges, and attend at general courts-martial.

The punishments that can be awarded to officers and soldiers for various offences are detailed in the Mutiny Act, the Articles of War, and the Queen's Regulations. A commanding officer can "reprimand" a commissioned officer, but can award him no other punishment. Arrest is not, as in most armies, recognised as a punishment, but is merely a preliminary to further proceedings. An officer, on the commission of an offence, is placed under arrest—that is, deprived of his sword and confined to his room—until the matter has been investigated and disposed of, or sent before a court-martial. A commissioned officer can be tried by a general court-martial only, and can be sentenced to death, penal servitude, imprisonment, cashiering, or dismissal, reduction on list of his rank, or reprimand. A soldier, on commission of an offence, is placed in confinement—that is, deprived of his arms and confined in the guard-room. At "orders" (*i.e.*, commanding officer's office hours) the next morning he is brought before the commanding officer, and the case investigated in presence of the officer commanding his troop or company, the adjutant, and the prisoner. If the offence is a minor one the commanding officer disposes of it summarily; his powers including admonition, confinement to barracks for periods not exceeding 28 days, carrying with it punishment drill up to 14 days, imprisonment not exceeding 168 hours, and stoppage of pay for absence. Drunkenness is punished by fines ranging from 2s. 6d. to 10s. If the offence is more serious, the man is remanded to the guard-room while the necessary steps are being taken for bringing him to trial, and is finally tried by a regimental, district, or general court-martial, according to the nature of the offence. The punishments that can be inflicted by court-martial are death, penal servitude for any period not less than five years, imprisonment for any period not exceeding two years, dismissal from the service, stoppages of pay, and forfeitures of pay, medals, service, &c. Flogging has been abolished except on active service, as also branding, and all such disgraceful punishments. Practically, military offences, with very few exceptions, are disposed of by regimental or district courts-martial, and by sentences of imprisonment not exceeding six months. A non-commissioned officer can only be reduced and punished by sentence of court-martial.

Sentences of penal servitude awarded to soldiers are carried out in the convict prisons with other convicts; but sentences of imprisonment are usually carried out in the military prisons. Military prisons were established in 1844, in order to avoid the necessity of mixing soldiers sentenced for military offences with ordinary criminals in county gaols. They are of two classes, the larger ones being under a governor, and the smaller ones under a chief warder. They are under the control of the Secretary of State for War, and under the immediate supervision of the officer commanding on the station (acting as his representative) and of the military visitors,—field officers serving at the station, by whom the prisons are periodically visited, and all serious offences investigated and punished. They are also inspected from time to time by the Government inspectors of convict prisons. There are eight military prisons in the United Kingdom, and six in the colonies; and the number of prisoners has recently averaged about 12 per 1000. Besides these prisons, "provost cells" are provided in every large barrack, in which short sentences of imprisonment not exceeding 28 or 42 days are carried out under the charge of a provost-sergeant.

Barracks.

In the earlier days of the standing army the barrack accommodation in England was altogether insufficient for the force maintained, and such as there was, was miserably bad. A considerable portion of the army was constantly billeted, camped, or lodged in buildings hired for the time, and every proposal to build barracks was jealously opposed in Parliament. Thus, in 1704 the total accommodation in barracks was only sufficient for 5000 men, and in 1792 did not exceed 20,000; but during the long war with France, partly in consequence of the large force kept permanently under arms, and partly also in consequence of the fears aroused by the revolutionary spirit which had penetrated into many of the large towns, barracks were constructed in all parts of the kingdom, and after the peace the accommodation far exceeded the wants of the army. Many barracks were then dismantled and sold, and others were allowed to fall into disrepair; but little was done towards improving the condition of the existing barracks until the Crimean war brought the army into notice again, and attention was drawn to the heavy rate of mortality among soldiers in peace time, mainly attributable to the defective construction and overcrowding of barracks. New barracks on improved designs were then built, and existing ones altered and reappropriated, so as to allow each man at least 600 cubic feet of air, and, in addition, provide recreation-rooms and other resorts for the soldier during the day.

The following estimate of the number and size of rooms required for a battalion of infantry on peace establishment will show the accommodation provided in modern barracks:—*Officers.*—Messroom, 45 feet × 25 feet, and 18 feet high; ante-room, 24 feet × 18 feet; kitchen, servants' rooms, larder,—altogether 13 rooms and cellars, &c. Commanding officer's quarters—6 rooms, of from 16 feet × 14 feet to 18 feet × 16 feet. Two field officers' quarters — 3 rooms each; 30 officers' quarters of one room each (often made with a recess or bunk for the bed), and 15 rooms for officers' servants. *Sergeants.*—Messroom, 40 feet × 20 feet; kitchen and storehouse for ditto; separate rooms for 7 staff-sergeants and 40 company sergeants. *Men.*—32 rooms to hold 18 men each, 45 feet × 20 feet, arranged by companies in blocks of four, with an ablution-room attached to each block; 48 separate quarters for married soldiers, each 16 feet × 14 feet. *Offices, Stores, and Workshops.*—Orderly-room, commanding officer's, paymaster's, and quartermaster's offices,—4 rooms; quartermaster's store, 40 feet × 20 feet; provision and issuing stores, two rooms, 18 feet × 16 feet; armourer's, tailor's, and shoemaker's shops, 3 rooms, from 16 feet × 14 feet to 16 feet × 32 feet; guard-room, with prisoners' room and lock-up; cook-house, 40 feet × 20 feet, with separate apparatus for each company; women's washing-house, 66 feet × 20 feet; latrines partitioned and screened. *Schools, Recreation-Rooms, Canteens, &c.*—Where no garrison schoolroom exists, a building, 50 feet square, divided into 2 large and 4 small class-rooms for the school. Recreation-rooms—2 rooms, 40 feet × 20 feet, fitted with bar in one room, and bookcases in the other. Canteen—bar, including counter and space in front, 24 feet × 12 feet; sitting-room for men, another for non-commissioned officers, and quarter for canteen sergeant. Skittle-alleys and ball-courts are also usually provided. Where no garrison hospital exists, a complete hospital establishment, including medical officer's office, surgery, dispensary, and store-rooms, quarters for sergeant and orderlies, cook-house, wash-houses, &c., and wards for 10 per cent. of the force, are included in the barrack. In constructing barrack-rooms the beds are usually arranged in two rows, with a passage of 5 feet between the beds, and 1 foot between head of bed and wall; giving a width of 20 feet. The barrack beds are of iron, made to double in the middle; during the day they are folded back, and the centre of the room thus cleared. Straw mattresses, blankets, and sheets are provided by Government; also forms and tables for day use. The arms are kept in racks by the side of the bed; knapsacks, kit, and accoutrements on shelves and pegs over the bed; 5 feet lineal space and 600 cubic feet are allowed per man. In hospitals 1200 cubic feet are allowed. In cavalry and artillery stables 1500 cubic feet are allowed per horse; the stalls are 5 feet or 5½ feet by 9 feet, with 12 feet down the centre of a double stable, or 7 feet on each side where the horses stand head to head.

Since the formation of the Control Department the construction, maintenance, and repair of barracks have devolved on the Royal Engineers; but the charge of them when once finished and handed over, the allotment of quarters, and the supply, maintenance, and repair of all barrack stores and movable furniture, rest with the Control Department. The existing barrack accommodation in the United Kingdom, according to the new appropriation, is sufficient for about 122,000 men,—88,000 in Great Britain, and 34,000 in Ireland; and when the works now in progress, or about to be undertaken, are completed, this will be raised to about 135,000. Of this, however, about 2 per cent. must be deducted for small detached forts and coast batteries, which cannot be occupied without great inconvenience to the troops so dispersed, and a margin of at least 10 per cent. must be left for barracks and rooms only partially filled, so that the available accommodation will not exceed 120,000.

Arms, Equipment, and Clothing.

The arms issued to the several branches of the service are supplied partly by contract, but mainly by the ordnance manufacturing establishments. The principal of these is the Royal Arsenal at Woolwich (see article ARSENAL), divided into the carriage factory, laboratory, gun factory, and experimental branch. From these factories are produced the whole of the guns and gun carriages for naval as well as land service now in use, and the greater proportion of the ammunition and equipment belonging to them. Rifles, sword bayonets, and swords are manufactured at the Royal Small-Arms Factory at Enfield, and gunpowder at the Royal Gunpowder Factory at Waltham Abbey; a considerable quantity of powder, however, is also supplied by contract. The various articles worn and carried by the soldier in the field, or issued to him and under his care, are usually classed under the three heads of arms and accoutrements (or equipment), clothing, and necessaries. Of these, the first are supplied and maintained by Government (though the soldier is held answerable for damage by carelessness or neglect), and under no circumstances become the property of the soldier. The articles included under the second head (clothing) are issued periodically to the soldier, and expected to last a given time; during this time he is required to maintain them at his own cost, but at the expiration of the period, and when replaced by the next issue, they become his property. Lastly, the articles termed necessaries are supplied free to the soldier on first joining, but afterwards have to be replaced and maintained at his own cost. The articles supplied as "clothing" vary slightly in different branches of the service, but usually consist of a tunic, a pair of trousers or overalls, and two pairs of boots annually, and a second pair of trousers biennially. Head-dresses, greatcoats, and leggings are issued at intervals varying from three to ten years, but these articles do not become the property of the soldier when done with. All clothing is supplied from the army clothing depôt at Pimlico; a certain amount is manufactured there, but the greater part is obtained by contract, and only examined and stored there. The bulk of the clothing is sent to regiments ready made-up, in sizes according to a size-roll furnished by the regiment; but a certain proportion is sent in material unmade, and an allowance is made to the master tailor of the regiment for making up such articles, and fitting the clothing generally. "Necessaries" include serge frocks or stable jackets, forage caps, shirts, socks, towels, brushes, combs, and other small articles, of which a stock is always kept on hand by the quartermaster of the regiment, and supplied by him to companies as required. These articles can either be obtained (on payment) from the clothing depôt at Pimlico, or purchased independently; but in the latter case the articles must be compared and found equal to the sealed patterns, and the price must not exceed the Government tariff.

England, from its insular position, has always been a great naval power rather than a military one. On her own element she has for years maintained an empire more undisputed than any power or potentate has ever claimed on land. The rule of Napoleon in the height of his fame was not so haughty and despotic on the Continent as was that of England at sea. Men still living remember the times when the British flag was saluted by every sail that traversed the sea in any quarter of the globe, and no ship, of any nation, dared to pass a British man-of-war without striking its flag. It was to the victories of her navy, and especially to Trafalgar, that England owed her immunity from invasion. It is natural, therefore, that the fame and popularity of the navy should partly have eclipsed the deeds of the army. And yet the British army has a history of which any nation might be proud. If it cannot count such a list of victories as Napoleon emblazoned on the banners of France, neither has it suffered such disasters; and it may lay claim to the longest continuous history of any army in Europe. The French army dates all its traditions from Napoleon's time;

Character of the British army.

not a trace remains of the regiments that served under Turenne, and Condé, and Luxemburg in the glorious days of the old monarchy, and even the banner under which they fought is proscribed. The Prussian army was almost unknown until the time of Frederick the Great; and Austrian regiments have been so often changed that it is difficult to trace their antecedents. But many English regiments trace back an unbroken history of more than two centuries, and fought, under the numbers and the names they still retain, with William III. in the Netherlands, and with Marlborough at Blenheim, Ramilies, and Malplaquet.[1] And their traditions are not confined to Europe. India conquered and permanently held; every colony in the world at one time wrested from its owners; the British flag planted on the ramparts of Cabul and Peking; and her arms carried into the fastnesses of Abyssinia and the forests of Ashantee;—such are among the deeds that attest the valour and enterprise of the English army. From time immemorial the inhabitants of the British Islands have been distinguished for a determined bravery and a physical power exceeding that of any other nation.

Modern peaceful experiences have confirmed the opinion as to the physical superiority of the Briton, and in this respect no rival has yet been found to the highly-fed English navvy. The army is composed of Englishmen, Scotchmen, and Irishmen, in the proportion of about 75 per cent. of the first, 10 per cent. of the second, and 15 per cent. of the last. The Englishman generally is above the average of nations in height and physical power. Even when the standard for the army has been at its lowest, it has been several inches above that of Continental armies. His strength lies especially in the upper part of the body—in the chest, shoulders, and arms—and he is ponderous rather than active. His lower limbs are not always proportionately developed, and the Englishman as a rule is not a good marcher, nor is he so hardy as the inhabitants of many other countries. In temperament he is calm and rather stolid, not easily roused to enthusiasm, and not full of romantic visions of glory, though not so insensible to such emotions as is often believed; slow, somewhat wanting in resource, and apt to grumble and show his discontent under hardships. On the other hand, he has a strong sense of justice, of right, and of duty, which can generally be successfully appealed to. His spirits rise to danger; he can always be depended on for battle; and his courage, if less fiery, is of a more stubborn and enduring kind than that of any other race. The Scotchman is less ponderous in frame, but more sinewy and active,—a better marcher, and more capable of enduring hardships and fatigue; more impetuous in action, though capable of a restrained energy very different from the reckless valour of the Frenchman or Irishman. The Scotch regiments have always been distinguished by a strong national feeling and clanship, producing an *esprit de corps* that cannot be surpassed by any *corps d'élite*. The Irishman is active, gay, careless, more ready in resource than the others, and often more reckless in fighting; but, on the other hand, less to be depended upon, and more difficult to hold in the bonds of discipline.

The English officer is drawn exclusively from the upper classes. His early education, his habits, and his traditions all fit him to be a leader of men. His *physique*, his intelligence, and the spirit of enterprise, are developed by those athletic exercises and field sports which distinguish the aristocracy of England. The character which especially distinguishes him is a love of enterprise. Much of his spare time is spent in travelling, or in sports of a more or less dangerous character. Not a war takes place in the most distant and unhealthy colonies, but crowds of volunteers are found for it. There is not a country in the globe but has been explored and traversed by English officers for their amusement, and wherever a war takes place they flock to it. Not so devoted, perhaps, as the officers of some nations to the details of their profession, they yet carry out all that is required of them with rigorous exactitude and a high sense of duty. But it is in the field, and when thrown on their own resources, that they show to most advantage. Trained by our Indian empire and colonial possessions to the life of a conquering nation, command comes natural to them; and the youngest subaltern, suddenly called to a position of responsibility, raises armies and carries on wars, and dominates all around him by his daring and energy. The histories of Clive, Sir Herbert Edwardes, and others, repeat themselves on a smaller scale whenever the occasion offers.

The social life of the English officer is unlike that of any other army. Off duty, the gradations of rank almost disappear, and all meet on a footing of equality as gentlemen. Our mess system, envied and copied by foreign nations, is only possible where such freedom exists. The officers live together, dine at a table always handsomely furnished, and often rich with trophies and records of the old history of the regiment, at which the president, perhaps the junior officer, is for the time superior; and wherever stationed, and under all conditions, retain the forms of high-bred society. The discipline of the English army, once proverbial for cruelty and harshness, is now the very reverse, and there is perhaps no army in which officers and men stand together on a more pleasant footing.

Of the character of the English army in war it is almost unnecessary to speak; it has written itself in history in a series of battles, often won against heavy odds, from Crecy, Poictiers, and Agincourt, to Waterloo. The highest eulogiums passed on it have been wrung from its adversaries. "L'infanterie Anglaise est la meilleur du monde; heureusement il n'y en a pas beaucoup," was Bugeaud's comment. "Le soldat Anglais," says General Foy, "possède la qualité la plus precieuse dans la guerre, le calme dans la colère." Readers of military history will remember Napier's vivid picture of the assault of Badajoz, when the troops, unable to advance, and yet scorning to retire, remained in the ditches to be shot down by the garrison. And our account may well close with Foy's description of the British infantry at Waterloo:—"La mort était devant eux, la honte derrière. En cette terrible occurrence les boulets de la Garde Imperiale et la cavalerie de France victorieuse ne purent pas entamer l'immobile infanterie britannique. On eut été tenté de croire qu'elle avait pris racine dans la terre, si ses bataillons ne se fussent ébranlés majestueusement quelques minutes après le coucher du soleil."[2]

INDIAN ARMY.

The history of the armies of India is the history of our Indian empire, and as such, in its most striking features, is treated elsewhere. The present notice, therefore, is confined to those details of organisation which do not fall within the province of a general history.

[1] It is greatly to be regretted that, for some unexplained reason, only the battles fought after the middle of the 18th century are borne by regiments on their colours.

[2] An anecdote of the Indian mutiny, peculiarly characteristic of officers and soldiers, may serve as a pendant to the opinion given above. A detachment was holding an advanced post against the attacks of a vastly superior force. The enemy gradually enveloped the post, and threatened to cut the retreat of its defenders; but the defence was maintained unshaken. At last an Irishman, with more military instincts, perhaps, than the rest, exclaimed, "Och, captain, captain, we're surrounded!" The officer's reply came sharp and stern, "What the devil's that to you, sir; look to your front;" and the defence was continued.

For military purposes India is divided into three great sections—Bengal, Madras, and Bombay. Under the term Bengal must be included Bengal proper, Assam, the North-West Provinces, Oudh, and the Punjáb; under Madras, Burmah; and under Bombay, the province of Sindh. The army of India has always consisted of three native armies, corresponding to the three presidencies, each associated with a certain number of British troops, Europeans in the service of the late East India Company, and forces furnished by the Imperial Government. This separation into three distinct armies was the natural result of the original foundation of separate settlements and factories in India; and each retains to the present day its own separate history and traditions.

Bengal army

Half a century after the establishment of the associations of merchant adventurers, whose first charter bears date 1600, the English traders in Bengal were still restricted by the native princes to a military establishment, as guard, of an ensign and 30 men; and this Liliputian force may be taken as the germ of the splendid army which now occupies India from Peshawur to Calcutta. In 1681 Bengal received the first reinforcement from Madras, in the shape of a "corporal of approved fidelity and courage, with 20 soldiers;" and two years later a company was sent from Fort St George (Madras), raising the little Bengal army to a strength of 250 Europeans. In 1695 native soldiers were first enlisted. The English had by this time moved to Calcutta, and there entrenched themselves; and in the years 1701–2, the garrison of that now flourishing capital consisted of 120 soldiers and seamen gunners. In 1756 Fort William was captured by Surajah Dowlah, and the terrible tragedy of the Black Hole of Calcutta was enacted; but vengeance followed promptly. An expedition was at once despatched from Madras, and on the 23d June 1757 the battle of Plassey established the British supremacy in Bengal. The little force, not exceeding 3000 men, with which Clive gained this astonishing victory, was formed mainly of Madras troops, and the 39th regiment, recently despatched from England,—the first royal regiment sent to India, and which now bears the motto, "Primus in Indis." The Bengal army was represented by a few hundred men only; but from this date the military power and conquests of the Company rapidly increased. A company of artillery already had been organised in 1748; and in 1757, shortly before the battle of Plassey, the 1st regiment of Bengal native infantry was raised. In 1759 the native infantry had been augmented to 5 battalions; in the following year 3 troops of dragoons were raised; and in 1763 the total forces amounted to 1500 Europeans and 12 battalions of native infantry, giving a strength of 11,500 men. In 1765 the army was further increased; the European infantry was divided into 3 regiments, and the whole force was organised in 3 brigades, each consisting of 1 company of artillery, 1 regiment European infantry, 1 troop of native cavalry, and 7 battalions of Sepoys. In 1766, consequent on the reduction of some money allowances, a dangerous combination of the officers of the Bengal army took place, by which they agreed to resign their commissions simultaneously. This combination was promptly put down by the then Governor and Commander-in-Chief, Lord Clive, to whom the Bengal army may be said to owe its existence. He found Bengal a ruined commercial agency in 1756; he left it, ten years after, a powerful empire.

The constant wars and extensions of dominion which took place during the next thirty years led to further augmentation of the army; the number of brigades and of European regiments was increased to 6; and in 1794 the Bengal army numbered about 3500 Europeans and 24,000 natives.

Madras army.

The first armed force in the Madras Presidency was the little garrison of Armegon, on the Coromandel coast, consisting of 12 guns and 28 soldiers. In 1644 Fort St George was built and garrisoned by 100 soldiers, and in 1653 Madras became a presidency. In 1745, when Fort St George was surrendered to the French, its garrison consisted of 200 Europeans, while a similar number, with the addition of 200 "Topasses" (descendants of the Portuguese), garrisoned Fort St David. In 1748 the various independent companies of factory guards at settlements on the Coromandel coast and other places were consolidated into the Madras European regiment. In the following year, Clive, with only 200 soldiers and 300 Sepoys, seized and held Arcot, the capital of the Carnatic, and on three several occasions defeated the troops of the Nabob and their French auxiliaries. From this year the military power of Madras may be dated. In 1754 the first royal regiment, the 39th, was sent there, followed in 1758 by three others. In 1772 the Madras army numbered 3000 European infantry and 16,000 natives, and in 1784 the number of native troops had risen to 34,000.

Bombay army

The island of Bombay formed part of the marriage portion received by Charles II. with the Infanta of Portugal, and in 1662 the Bombay regiment of Europeans was raised to defend it. In 1668 the island was granted to the East India Company, and the regiment at the same time transferred to them. In 1708 Bombay became a presidency, but it did not play so important a part as the others in the early extension of our power in India, and its forces were not so rapidly developed. It is said, however, to have been the first presidency to discipline native troops, and Bombay Sepoys were sent to Madras in 1747, and took part in the battle of Plassey in 1757 In 1772 the Bombay army consisted of 2500 Europeans and 3500 Sepoys, but in 1794, in consequence of the struggles with the Mahratta power, the native troops had been increased to 24,000.

In 1796 a general reorganisation of the Indian armies took place. Hitherto the officers in each presidency had been borne on general "lists," according to the branches of the service to which they belonged. These lists were now broken up, and cadres of regiments formed. The colonels and lieutenant-colonels remained on separate lists, and an establishment of general officers was created, while the divisional commands were distributed between the royal and Company's officers. Further augmentations took place, consequent on the great extension of territory and the complete assertion of British supremacy. In 1798, at the outbreak of the war with Tippoo Saib, the native infantry in India had been increased to 122 battalions; and the force which General Harris took from Madras for the attack on Seringapatam consisted of 5000 Europeans, 14,000 native troops, 40 siege guns, 64 field guns, and the Nizam's contingent, numbering 6000 men. In 1808 the total force in India amounted to 24,500 Europeans and 154,500 natives.

The first half of the 19th century was a history of wars and annexations, and further augmentations of the army took place. Horse artillery was formed, and the artillery service increased to a most powerful footing. "Irregular cavalry" were raised in Bengal and Bombay, commanded by picked officers, and recruited from a better class of troopers, who received high pay, on the condition of finding their own horses and equipment. "Local forces" were raised in various parts from time to time, the most important being the Punjáb irregular force (raised after the annexation of the Punjáb in 1849), consisting of 3 field batteries, 5 regiments of cavalry, and 5 of infantry, and the Nagpore and Oudh irregular forces. Another kind of military force, which had been gradually formed, was that called "contingents,"—native troops raised by the native states under our protection. The strongest of these was that of Hyderabad, originally known as the Nizam's army, and consisting of two brigades of infantry and cavalry, with artillery. Changes were also made in the organisation of the army. The staff was enlarged, sanitary improvements effected, manufacturing establishments instituted or increased, and the administration of the army generally improved.

The officering and recruiting of the three armies was in all essentials similar. The officers were mainly supplied by the Company's Military College at Addiscombe (established in 1809), and by direct appointments under the patronage of the directors. The Bengal army was recruited from Hindustan, the infantry being mostly drawn from Oudh and the great Gangetic plains. The soldiers were chiefly high-caste Hindus, a sixth being Mahometans. The cavalry was composed mainly of Mahometans, recruited from Rohilcund and the Gangetic Doab. The only other elements in the army were the four Ghoorka regiments, enlisted from Nepaul, and the local Punjáb irregular force. The Madras army was chiefly recruited from that presidency, or the native states connected with it, and consisted of Mahometans, Brahmins, Mahrattas, Telingas or Gentoos, and Tamils The Bombay army was recruited from its own presidency, with some Hindustanis, but chiefly formed of Mahrattas and Mahometans; the Bombay light cavalry mainly from Hindustan proper

Indian mutiny

In the year preceding the great mutiny the Indian army had reached its highest strength. The establishment in the several presidencies was as follows:—

	Bengal.	Madras.	Bombay.	Total.
British Cavalry Regiments	2	1	1	4
,, Infantry Battalions	15	3	4	22
Company's European Battalions	3	3	3	9
European and Native Artillery Battalions..	12	7	5	24
Native Infantry Battalions..	74	52	29	155
Native Cavalry Regiments...	28	8	3	39

Including the local and irregular troops (about 100,000 strong), the total strength amounted to 38,000 Europeans of all arms, with 276 field guns, and 348,000 native troops, with 248 field guns,—truly a magnificent establishment, and, outwardly, worthy of the great empire which England had created for herself in the East, but inwardly unsound, and on the very eve of crumbling to pieces.

It would be impossible, within the limits of a short article, to do more than briefly summarise the causes which led to the great Sepoy mutiny of 1857. For many years the discipline of the Bengal army had been relaxed. The system under which the ablest regimental officers were withdrawn to staff and civil employ was incompatible with efficiency, the centralisation of the army administration was excessive, and the powers of commanding officers had greatly diminished. The supposed wrongs of Oudh stirred up the soldiers so largely recruited from that province, and the religious prejudices of those otherwise well disposed were inflamed by the secret emissaries of the disaffected. The Sepoys were told that the Government wished to force them to break their caste and abjure their religion, that they were to be sent across the sea to die in foreign and detested lands, or to be sacrificed on their own shores. Even the ridiculous endeavour to assimilate native to British soldiers in outward appearance was turned to account by these emissaries. The "greased cartridges" were but the spark which set the whole aflame. The miserable delusions spread, the loyally-disposed cast in their lot with the disaffected, feeling that when once a mutinous spirit had been shown all was lost to them as a military body, and the Bengal native army was in a short space of time only a chaotic mass of disbanded and mutinous soldiers.[1] The story of the rebellion is the history of those days, and cannot be treated in this place. Fortunately for our power in India, the mutiny did not spread to the Madras or Bombay armies; and in the darkest days our ancient enemies the Sikhs not only remained faithful, but came forward to render us powerful assistance.

Reorganisation.

By the autumn of 1858 the mutiny was virtually crushed, and the task of reorganisation commenced. On the 1st September 1858 the East India Company ceased to rule our Indian empire, and Her Majesty's Government took up the reins of power. On the important question of the reorganisation of the Indian army the opinions and advice of the most distinguished soldiers and civilians were invited. Masses of reports and evidence were collected in India, and by a royal commission in England. On the report of this commission the new system was based. They recommended the abolition of a local European army, and the amalgamation of the existing one with the royal army; that the native army should be enlisted for general service, and be of mixed nationalities and castes; that the irregular system should mainly obtain in the native cavalry; and that the native infantry should be mainly regular

The European force was permanently increased, while the native army was largely reduced. The Indian artilleries were transferred to the Royal Artillery, the Company's European cavalry became the 19th, 20th, and 21st Hussars, and their European infantry became regiments of the line numbered 101 to 109. The transference of the Company's Europeans to the Crown was not unattended with trouble The men considered that faith had not been kept with them, and a mutinous spirit was shown Ultimately they were offered their discharge, which a large number accepted.

The European officers of the native armies, and those officers and men who did not accept service in the new royal regiments, now formed with the native soldiers the new Indian army. The reorganisation of this by the Indian Government was a task of no ordinary difficulty, involving much besides reconstruction. Many of the levies hastily raised during the mutiny had to be disbanded, or formed into line regiments, and various miscellaneous corps had to be got rid of. The Government was further hampered by the necessity for providing for the large number of officers whose regiments no longer existed. In 1861 a "staff corps" was formed in each presidency, "to supply a body of officers for service in India, by whom various offices and appointments, hitherto held by officers borne on the strength of the several corps of the Indian forces shall in future be held." Promotion in this corps was to be by length of service,—twelve years to attain the rank of captain, twenty years that of major, and twenty-six years that of lieutenant-colonel. The staff corps was filled up by a large number of Indian and British officers holding various staff employments (the new regimental employments being counted as staff duty), and all kinds of civil posts and situations, and has been gradually opened wider, till it includes the great majority of the Indian officers. The new organisation of the cavalry and infantry of the Indian army was promulgated in 1863, but did not take effect in Bombay and Madras till 1864 and 1865. Cavalry regiments are on the "silladar" or irregular system; their establishment consists of 1 commandant, 1 second in command (also commanding a squadron), 2 squadron officers, 1 adjutant, 2 doing duty officers (Europeans), and 13 native officers, 444 non-commissioned officers and troopers, or "sowars." The infantry battalions have each 1 commandant, 2 wing commandants, 1 adjutant, 1 quarter-

[1] Of 74 native infantry regiments, 45 mutinied, 20 were disarmed, and 3 disbanded Six only remained true.

master, and 2 doing duty officers (Europeans), 16 native officers, and 696 natives of all ranks.

Present strength, composition, and administration

The total strength of the army of India in 1873 was 6162 European officers, 60,174 European non-commissioned officers and men, and 123,671 natives. The supreme military power is the Viceroy and Governor-General in council. The military member of that council is *de facto* War Minister, and the military department of the Government of India the War Department. The Commander-in-Chief of the army is the executive military power, and the responsible adviser of Government, as well as local Commander-in-Chief in Bengal. The Madras and Bombay Presidencies have military departments and local commanders-in-chief, but subordinate to the supreme Government of India; each presidency, however, has certain local peculiarities in its own military system and its own army departments. The army departments are the commissariat (charged with the supply of provisions, forage, fuel, light, and transport), the ordnance department (charged with the custody and supply of all warlike stores), the clothing department, medical department, stud department, &c. The commissariat is officered from the combatant ranks of the army, the subordinates being also drawn permanently from its ranks, and is a most excellent and powerful department. The ordnance department is officered from officers of the Royal Artillery, who, as "commissaries of ordnance," have charge of the various arsenals and magazines in the country. The whole of British India is divided into divisions and districts, and the command is exercised by royal or Indian officers according to a proportion fixed. The staff is selected from the officers of the British corps in India, the staff corps, and the Indian army, and the system is similar to that in England and the colonies, except that the tenure of brigade majorships is limited to three years.

The following table shows the detailed constitution of the army of India in 1873:—

	Bengal Army.	Madras. Army	Bombay Army	Total.
Europeans.				
Artillery—				
Horse Field Batteries...	33	13	12	58
Heavy and Mountain Batteries	4	1	1	6
Garrison Batteries......	11	6	5	22
Engineers—Companies.....	1	1	1	3
Cavalry—Regiments	6	2	1	9
Infantry—Battalions........	32	9	9	50
Natives.				
Artillery—Mountain Batteries................	4		2	6
Cavalry—Regiments........	26	4	7	37
Engineers—Companies.....	10	10	5	25
Infantry—Battalions..... .	60	40	30	130
Strength—Europeans	41,055	13,214	12,067	66,336
Natives...	62,955	33,963	26,753	123,671

The following gives the strength of the several arms:—

	European.	Native.
Infantry, ...	45,962	101,134
Cavalry, ...	4,347	18,575
Artillery—Men, . .	12,306	896
,, Guns, . .	370	36

The Punjáb field force of 4 batteries of artillery, 5 regiments cavalry, 4 regiments Sikh infantry, and 6 regiments Punjáb infantry, is included in the Bengal army. The "Hyderabad contingent," of 4 field batteries, 4 cavalry and 6 infantry regiments; the "Mysore" troops, of 6 regiments of cavalry and 4 of infantry; the "Nair brigade," of 2 battalions of infantry and four guns; and other minor local forces and contingents, are not included in the above.

The Bengal army is composed chiefly of Mahometans, Brahmins and other Hindu castes, Rajpoots, Jâts, Punjábees, natives of Trans-Indus, and hill-men. Some are regiments entirely of one race, as the Ghoorkas, while others are mixed entirely or by companies; but the composition of every regiment has been definitively laid down. There are no special restrictions on caste or race, but care is taken to prevent an undue preponderance of any class. Enlistment is purely voluntary. Recruiting is carried on by parties detached, or by non-commissioned officers and men on furlough. Pay and pension are fairly good, though depreciated by the general rise in prices; pension being obtainable by men invalided after fifteen years' service. The native officers are appointed from the non-commissioned officers, and though a respectable body of men, are not sufficiently educated. It is, however, contemplated to give natives of rank and position direct commissions. The British officers of the Indian army, generally, are obtained through the medium of the staff corps, which is filled by volunteers from the British army, and now supplies the native armies of India with regimental officers.

The Madras native army is composed of a few Christians, Mahometans, and Mahrattas, and a large number of Telingas or Gentoos, and Tamils. The infantry battalions are organised as in the Bengal army. The cavalry are mostly composed of Arcot Mussulmans, descendants of the soldiers of the Nawab of the Carnatic. This cavalry is not "silladar," as in Bengal or Bombay, and the native establishment is weaker, consisting of 12 native officers, 75 non-commissioned officers, and 300 privates. The army is recruited as in Bengal, but has a peculiar institution of its own, viz., the "recruit and pension boys" (sons of soldiers or pensioners) attached to each regiment, and transferred to the ranks when of sufficient age and approved of,—a valuable institution, and one which gives a powerful hold upon the fidelity of the men.

The Bombay army resembles that of Bengal in recruiting, organisation, and equipment. It is composed of a few Christians, some Brahmins and Rajpoots, and other Hindu castes, but mainly of Mahrattas and Purwarees, with a few Punjábees and natives of Trans-Indus.

It is difficult to draw comparisons between the soldiers of our Indian forces, recruited from so many different parts of the empire. The most warlike, undoubtedly, are the inhabitants of Scinde, the Punjáb, and Trans-Indus. Perhaps next come the men of Rohilcund, Rajpootana, Oudh, and the Mahrattas. These races possess a greater aptitude for military training, and are generally of a better physique than the inhabitants of the Southern Peninsula. But it is too much to affirm that the former are "born soldiers," the latter only "soldiers by education." The ploughshare has already replaced the sword in many parts, and more and more are once turbulent tribes becoming peaceful tillers of the soil. Of the actual value of native troops it is still more difficult to form a true estimate. The Sikhs, both as friends and foes, have proved themselves gallant soldiers, not unworthy of being matched with Europeans. The ordinary Sepoy, under the guidance of British officers, has furnished many examples of heroism and devotion. It is said that a Bengal regiment successfully stood the brunt of a charge from the French at the battle of Porto Novo in 1782; and the devotion of Clive's Sepoys at Arcot has passed into a proverb. At the siege of Delhi in 1857, native regiments sustained losses which few European troops could have borne, and crowds of men in hospital, with wounds only part healed, volunteered to join in the final assault. But without their English officers they are of little value; the Asiatic, as a rule, cannot face the European, and it would be dangerous to trust to them in a war against a Western invader. They are useful auxiliaries, and relieve the European soldier of much of the fatigue inseparable from the task of garrisoning so large an empire and protecting its frontiers. But the mutiny proved the danger of relying on them, and taught the lesson, never, it is to be hoped, to be forgotten, that our Indian empire must be held, not by native armies, but by British armies.

Many important changes and improvements have taken place since the great reorganisation of the Indian armies was commenced in 1858. The education of the whole army has been improved; musketry, gymnastic, and garrison instruction has been introduced; and strict tests are now required of candidates for the staff, and for promotion in all grades. Annual camps of exercise have been instituted, where large bodies of troops are massed, and opportunities for higher tactical training afforded. The commissariat department has been enlarged, the military account department remodelled, the *matériel* of war and its manufacture vastly improved. The new system of reliefs of British troops has greatly shortened the tour of Indian service, splendid barracks have been built, hill sanitariums extended, so that about 10,000 British troops are now located in the hills during the hot weather; by these means, and a liberal expenditure on sanitary requirements, the death-rate among European troops has been reduced to one-half. Other great questions still remain to be dealt with. The local peculiarities of the presidencies seem likely to give way before the increasing intercommunication throughout India. The staff corps was an expedient, and answered its purpose for the time as such, but experience has shown defects in its constitution. The officering of the native regiments will always remain a subject for careful and anxious consideration. The British rule in India may never again be put to such a severe test as that of 1857, but a wise government will not the less prepare for a day of danger which may yet come for our Indian empire.

Canadian Militia.

To complete the account of the military forces of the British empire some notice of the Canadian militia is necessary. Until recently Canada was one of the great military out-stations of the English army, and was garrisoned by a considerable force of British troops distributed throughout the Dominion. Recently these troops were gradually withdrawn, and the colony left to its own resources; and since 1871 the regular forces maintained in the Dominion have been reduced to the 2000 men forming the garrison of Halifax, which alone is still occupied as an imperial station. The defence of Canada is provided for by a large volunteer and militia force. By an Act passed in March 1868, all male inhabitants between the ages of 18 and 60 are liable to serve in the militia, exemptions being granted to judges, ministers of religion, professors, and a few others. The men thus liable are divided into four classes, denoting the order in which they would be called out for service—the first including all single men between the ages of 18 and 30; the second, single men between 30 and 45; the third, married men, or widowers with children, between 18 and 45; the fourth, all between 45 and 60. The militia is divided into an active and a reserve force. The active force includes the volunteers, and the regular and the marine militia. Its strength is fixed at 45,000, divided among the various districts in proportion to their population. The contingent must be furnished either by volunteers, or, if sufficient volunteers do not present themselves, by means of the ballot.

Service in volunteer corps lasts for three years, and in the regular militia for two years; the periods of training last from eight to sixteen days annually. Money is granted for this purpose by Government; and every year camps of instruction are formed in each of the eleven military districts into which Canada is divided, at which the militia of the district are assembled and trained. Two schools of military instruction for infantry officers are established in each of the provinces of Ontario and Quebec, and one in each of the provinces of New Brunswick and Nova Scotia. There are also two schools of gunnery, which have permanent batteries of artillery, at Kingston and Quebec. The infantry are armed with long Snider rifles, the cavalry with Spencer carbines and swords. The field artillery includes nine batteries, all well horsed. The "reserve militia" number 656,066 men, but have not hitherto been organised or drilled. The command of the whole force is vested in Her Majesty, who may call it to arms, wholly or in part, whenever necessary.

German Army.

By the "constitution of the German empire," bearing date the 16th April 1871, the land forces of all the states of Germany form a united army under the command of the emperor. The German army thus includes the contingents of Prussia, Bavaria, Saxony, Würtemberg, Baden, and a number of minor states, all raised and organised (with insignificant variations) on the Prussian model. The peace strength of the army is fixed at 401,659 men,[1] or about 1 per cent. of the population; and the budget is established on the basis of 257 thalers, or £38, 11s. per soldier present with the colours. The army is organised in 18 army corps, of which 14 are furnished by Prussia and the states whose contingents are amalgamated with hers, 2 by Bavaria, 1 by Saxony, and 1 by Würtemberg. As the Prussian army thus constitutes three-fourths of the military forces of the empire, and is the model on which not only the other contingents, but to a certain extent the armies of most European powers, have been formed, a detailed account of its organisation will serve as an introduction to the necessarily brief notices of the other armies of Europe.

The Prussian army, like the monarchy, is of comparatively recent origin. Its European reputation dates from the wars of Frederick the Great, but it was his father, Frederick William I., aided by Prince Maurice of Dessau, who really created the army which Frederick II. led to victory, and which numbered 70,000 men, admirably trained and equipped, when the latter ascended the throne. History of the Prussian army.

The infantry had been especially perfected by Prince Maurice; and under Frederick's care the cavalry soon rivalled, if it did not excel it. The gallant struggle against overwhelming odds, and the series of brilliant victories which marked the Seven Years' War, raised the reputation of the army to the highest pitch; and the superb force of 200,000 men which he bequeathed to his successor was justly accounted the best in Europe. It was hardly, however, a national army, and its excellence was owing rather to Frederick's genius, and to his system of discipline and instruction, than to the goodness of the material. The cavalry, it is true, and the hussars especially, were recruited almost entirely from the Prussian states, and from the sons of the small farmers or better class peasants; but the infantry was raised from all sources, and was largely composed of foreigners, deserters, and vagabonds of all kinds. With Frederick's death, the genius which had animated it, and which alone gave value to such heterogeneous materials, was gone. It still retained its imposing appearance and precision of movement, and its overweening self-confidence. But at the first encounter with the armies of Napoleon it

[1] One-year volunteers are not included in this number.

fell to pieces, and after a series of crushing defeats, Prussia found herself at the feet of the conqueror, shorn of half her territory, obliged to receive French troops in all her towns and fortresses, and only existing as it were by sufferance. But in these very disasters were laid the seeds of her future greatness. By the treaty of Tilsit the Prussian army was limited to 43,000 men. This limitation suggested to Scharnhorst what was known as the "krümper," or "short-service" system already described. The bitter humiliation and suffering endured under the French yoke aroused a national spirit which was capable of any sacrifices. Every Prussian was eager to be trained to fight against the oppressor of his country; and when Prussia rose in 1813, the armies she poured into the field were no longer mercenaries, but national armies, imperfectly trained and organised it is true, but animated by a spirit which more than compensated for these defects. At the close of the war her rulers, with far-seeing sagacity, at once devoted themselves to organise on a permanent footing the system which had sprung up under the necessities and enthusiasm of the moment. The conscription, compulsory personal service, and a three years' term in the ranks, with further periods in the reserve and landwehr, were then introduced; and though variations have subsequently been made in the distribution of time, the principles were substantially the same as those now in force. By the law of 1814 the periods of service were fixed at three years in the army, two in the reserve, and fourteen in the landwehr, and the annual contingent at 40,000 men. As the population increased, it was felt that the service was unequally distributed, pressing unnecessarily heavily on some, while others escaped altogether. Further, the experiences of 1859, when Prussia armed in anticipation of a war with France, aroused great doubts as to the efficiency of the landwehr, which then formed the bulk of Prussia's forces, and of whom many had been as long as ten years away from the colours. Accordingly, by the law of 1860 the annual contingent was fixed at 63,000, the period in the reserve was increased from two to four years, and that in the landwehr reduced from fourteen to five. The total armed force thus remained nearly the same (12 contingents of 63,000, in place of 19 of 40,000), but the army and its reserves were more than doubled (increased from 5 × 40,000 to 7 × 63,000) while the landwehr was proportionately reduced.

This change was not effected without great opposition, and led to a prolonged struggle between the king, guided by his able and ambitious minister Bismarck, and the parliament; for some time the king ruled and levied taxes in open defiance of parliament and the constitution, and it required the brilliant successes of 1866, and the position thereby won for Prussia, to reconcile the nation to the new law.

Military law of Germany.

By the present "military law of the German empire," every German is liable to service (*wehrpflichtig*), and must render such service personally. Neither substitutes nor purchase of exemption are allowed, and those who are physically unfit for the ranks may be required to render such other services—as hospital attendants, tradesmen, &c.—as they are capable of. Every German capable of bearing arms belongs to the army for seven years, commencing at the age of 21, and afterwards to the landwehr for five years. Army service is divided between the ranks and the reserve, three years being spent in the former and four in the latter. The annual contingent of recruits is not now permanently fixed, but is determined by the number required to keep up the peace establishment, and is estimated at from 120,000 to 130,000 annually. By fixing the total peace establishment instead of the annual contingent, the authorities have gained the power of largely augmenting the army without raising the budget or attracting public attention, as by passing men into the reserve before their time they can always increase the contingent required to complete the regiments, and thus the total number of trained men available in war. Thus, before the war of 1870, commanding officers of regiments were directed to send home a certain number of the most intelligent men after two years' service; and since the war a large proportion of the infantry have been subjected to two years' training only.

Per[manent] or[ganisa]tion.

The military organisation of Germany is based on the territorial divisions of the empire. With the exception of the Prussian guard corps, which is recruited generally throughout the kingdom, each army corps has a corps district (*Bezirk*) within which it is raised, recruited, and stationed. The first six army corps districts correspond to the six provinces of old Prussia, the 7th and 8th to the Rhenish provinces. The 9th, 10th, and 11th were formed from Hanover, Schleswig-Holstein, and the minor states annexed by Prussia in 1866; the 12th by the kingdom of Saxony, the 13th and 14th by Würtemberg and Baden, the 15th by Alsace and Lorraine, and the 16th and 17th (called 1st and 2d Bavarian army corps) by the kingdom of Bavaria. The following details apply strictly to the Prussian provinces only.

The corps districts are subdivided into division and brigade districts, and these again into landwehr battalion districts, corresponding to the civil *Kreis*, or circle. As a rule, for each infantry regiment there are two corresponding landwehr battalion districts, from which the former draws its recruits and reserves. The battalion districts, again, are subdivided into company districts, of which there are from 3 to 6 to a battalion. Every town and village has thus its appointed place in the general organisation, and this is indicated on notice boards conspicuously placed at all the entrances.

Raising annual contingent.

At the beginning of each year lists are prepared from the parish registers of all young men who have attained their twentieth year, and to these lists are added the names of those who, though still liable to service, have been allowed to stand over from previous years. In the spring, about May, the battalion recruiting commission commences its labours. This commission is composed of the landwehr battalion commander, the landrath or chief civil functionary, two officers, and a surgeon, as permanent members, and four local members taken from the more respectable inhabitants of the different villages.

The commission having notified the days of its visiting the headquarters of the several company districts, the youths are mustered there accordingly, and inspected. Those who are found physically unfit for any service are struck off the lists altogether. Others who are too young and unformed for military service are put back for a year. Many also are permitted to stand over on personal or family grounds, the commission being allowed great latitude in granting temporary exemptions.

Every young man can be called up three years in succession, and as a rule the majority of the recruits are put back one year at least on medical grounds, but at the end of the third he must either be definitely passed or exempted. Those who are exempted in their third year are passed into the *Ersatz* reserve, where they undergo no training, and are free of service in peace time, but in war can be called out and sent to the depôts to replace the casualties in the active army. Men below the regulation standard, but otherwise fit for the army, are passed into the *Ersatz*

[1] The contingent of recruits for 1872-3 was fixed at 190 per battalion. As the peace strength of the battalion, exclusive of the permanent cadres, is about 450, it is evident these cannot all receive their full three years' training.

reserve; as also only sons of widows, and others who are the sole supports of families, or who have, or have lost, brothers in the army. Although exemptions are much more charily granted in the third than in the first and second years of liability, they are still sufficiently numerous to soften materially the hardships of compulsory service. Finally, after all "exemptions" and "adjournments" have been made, there remain those passed as fit for service, and from these the required number are chosen by ballot. But the ballot is almost nominal. In 1862, for instance, when the number coming of age amounted to 227,000, only 69,000 were left on the lists for the ballot—63,000 being the required contingent — and in many districts the ballot was not applied at all. In 1867, 262,000 came of age, 110,000 were passed for the service, and about 100,000 taken. The system of exemptions is so elastic that practically the recruiting commission can select, by a process of elimination, those best fitted for service, and abolish the element of chance. A margin of about 10 per cent., however, is usually allowed; those who draw the lucky numbers are passed into the *Ersatz* reserve, but remain liable for a year to fill any accidental vacancies in the peace establishment.

The men drawn for the army are then told off to the different branches of the service; men with good chests and good feet to the infantry, men accustomed to horses to the cavalry, gamekeepers and foresters to the rifles, men of high standard to the guard, those of inferior physique to the train, carpenters and mechanics to the engineers, and a certain proportion of shoemakers, tailors, saddlers, &c., to all regiments and corps. The guards recruit throughout the kingdom generally; the cavalry, artillery, fusiliers, and rifles throughout their own corps districts; while the infantry regiments draw their recruits as far as possible from the corresponding landwehr battalion districts. The proceedings of the battalion recruiting commissions are revised by brigade commissions, who distribute the recruits to regiments and corps, and these again by a corps commission. The final decision and allotment to regiments is usually completed about September. From that time the men are called recruits, and amenable to military law, but are given passes until the 15th October, the date on which they join their regiments.

These conscripts form the great bulk of the army; but there are other classes, also, serving under varied conditions. Of these the most important are the "one-year volunteers," young men of means and education who, on condition of passing certain examinations and bearing all expenses of clothing, equipment, &c., are allowed to pass into the reserve after one year's service only. This system is a great boon to the middle and professional classes, who thus materially reduce the interruption which the full term in the ranks would cause in their education; and every effort is made to render the service as light as is consistent with thorough instruction. Many of these pass the requisite examinations for officers' rank, and become officers of landwehr, or qualify as non-commissioned officers, and serve as such if recalled on mobilisation. A certain number of youths enter voluntarily for three years, gaining the privilege of serving at an earlier age, and choosing their own regiments. The non-commissioned officers are mostly "re-engaged men." Re-engagements are allowed for various periods, and each squadron or company has several "*Capitulanten*," smart young men, who have engaged to prolong their service in the ranks with the object of getting promotion. In the cavalry it is common for men to engage to serve four years instead of three, in consideration of which their time in the reserve is reduced by one year, and that in the landwehr by two years. Finally, there are a certain number who serve for a given number of years in return for advantages received in the way of education or maintenance from Government; such are the pupils of the non-commissioned officers' school and of the school of forestry, &c.

After completing his term in the ranks the soldier is passed into the reserve, retaining, however, his place in his regiment, borne on its books, and liable to be recalled to it in case of war. The *reservist* is supposed to take part in at least two manœuvres, not exceeding eight weeks, during his term of reserve service. On completing his seven years' army and reserve service he leaves his regiment and passes into the landwehr, and is taken on the lists of the corresponding landwehr battalion for the remaining five years of liability. The landwehr battalion is the basis of the local organisation, both for recruiting and mobilisation. As a rule, to each three-battalion regiment of the line is attached a two-battalion landwehr regiment. These two are connected as closely as possible; they bear the same number, the line regiment draws its recruits from the battalion districts, furnishes the staff for their cadres, and passes its men into their ranks.

In peace time the landwehr battalions exist only in cadre, viz., a commanding officer, adjutant, and three clerks and orderlies per battalion, and a sergeant-major and two non-commissioned officers per company. These are charged with keeping the registers of the names and addresses of all reserve and landwehr men in their districts, and on mobilisation the whole labour of summoning, collecting, and forwarding the men to their destination falls on the landwehr battalion commander and his staff. The fusilier reserve landwehr battalions form a peculiar feature in local organisation. Each army corps has a fusilier regiment, which does not draw its recruits from a particular subdistrict, but, like the cavalry and special corps, from the corps district generally. But to each fusilier regiment is attached a reserve landwehr battalion and district, bearing the same number, but used to equalise and fill up the regiments throughout the corps district generally, remedying deficiencies in the regimental quotas of recruits or reserve men, and forming, in fact, a great central depôt of recruits and reserves. It has always for its district some important town or centre of commerce, where the floating population is largest and local attachment weakest, and whence also the communications to all parts of the province are easiest, and is allowed a considerably larger staff.

The following is an approximate estimate of the resources in men at the disposal of the German empire:—

Standing army, ...	400,000
Reserves of the army, . . .	450,000
Landwehr, ...	500,000
Total trained men, . .	1,350,000

When the army is mobilised, about 1,250,000 of these are embodied, and 100,000 remain still available of men not trained, but registered and liable to be called out; then there are the next year's contingent of recruits, 120,000, and *Ersatz* reserve, which cannot be estimated under 800,000,—making, with her trained soldiers, a total of about $2\frac{1}{4}$ millions.

Prussian Army.

The Prussian army is divided into *field troops*, who in peace time form the standing army and the school of instruction in arms for the nation, and in war time, augmented by the reserves, become the active army; *Depôt troops* (*Ersatztruppen*), who have no existence in peace time, but in war time are formed of cadres supplied from the field troops, and filled up by recruits and reserve men, and whose duty it is to maintain the active army at full strength; and *garrison troops* (*Besatzungstruppen*), principally formed of the landwehr, and existing only in cadre in peace time, but who are embodied and take up the garrison duties and home defence when the active army takes the field, and also occasionally reinforce it.

The *field troops* consist of—

115 Regiments of Infantry.
14 Battalions of Rifles.
73 Regiments of Cavalry.
14 Brigades of Artillery.
14 Battalions of Pioneers.
14 Battalions Military Train.

Infantry.—The infantry is classed as guards, grenadiers, fusiliers, and line. The nine regiments of guards are composed of picked men, and are in every way *troupes d'élite;* four of them are maintained at a special increased peace establishment. The grenadier regiments only differ from the line in name and in some trifling badges, relics of former times. The fusiliers are the representatives of the old light infantry, and are specially intended for outpost duty, skirmishing, &c. The men are chosen for activity and intelligence, and their armament differs slightly, but in organisation they are the same as the line. A fusilier regiment is attached to each army corps.

An infantry regiment has three field battalions, of which the third is called the fusilier battalion. A battalion consists of four companies, and has a peace strength of 552 of all ranks, and a war strength of 1022. A regiment on war footing numbers 60 officers, 3000 men, 73 non-combatants, with 105 horses and 19 waggons. Besides the three field battalions, a fourth or depôt battalion, 1240 strong, is formed on mobilisation. This includes a company of tradesmen 200 strong, who are required to supply all clothing, &c., and execute all repairs required by the battalions in the field. The depôt battalion is formed partly of the next contingent of recruits, who are called out at once on mobilisation, and partly of the oldest classes of reserve men, or, if these do not suffice, of the youngest class of landwehr; any men in the field battalions who, from want of instruction or other causes, are not considered fit for immediate service, are also transferred to the depôt. The field battalions always maintain direct communication with it, and as soon as their losses amount to 10 per cent. of their strength, draw on it for the necessary reinforcements.

The Prussian infantry stands in three ranks on parade, the third rank being composed of picked shots (*Schützen*), who formerly did all the skirmishing. But for drill and manœuvring the common formation is that of company columns, the company being divided into two "*Zugs*" or subdivisions, standing at six paces' distance, and the third rank being withdrawn and formed into a separate *Zug* (*Schützenzug*), two deep, in rear of the others. The Prussian drill, which for many years was the model for Europe, has lately become so again, and since 1866 the company column formation, by which more independence is given to the captains, and greater freedom of movement to the battalion generally, has been adopted by most armies.

The Prussians were also the first to adopt the breech-loader, which they used with marked success against the Danes in 1864 and the Austrians in 1866. Up to 1870 they were armed with the needle-gun, the earliest, but probably also the worst, form of breech-loader; but their losses from the French chassepôt convinced them of the necessity of an improved weapon, and the infantry is now being armed with the Mauser rifle. The infantry soldier of the line carries a long breech-loading rifle, with bayonet always fixed, a short sword, and 80 rounds of ammunition; a reserve of 20 rounds per man is also carried in the battalion ammunition waggon. Fusilier regiments, and fusilier battalions of other regiments, are armed with a shorter rifle without bayonet, but carry a sword which can be fixed and used as such when required. The uniform is a dark blue tunic, grey trousers with red stripe, helmet of black leather, with brass ornaments and spike (*Pickelhaube*), and boots into which the trousers are generally tucked for marching. The different army corps are distinguished by the colour of the shoulder cords. The knapsack is of brown calfskin, rather large, but shaped to fit the back. The belts of grenadier and line regiments are white, those of fusilier regiments black.

Rifles.—The rifles (*Jäger* and *Schützen*) are not organised in regiments, but form independent battalions, of which the guard corps has two and the other army corps one each. Their organisation, and peace and war establishment, are almost identical with that of a line battalion, but on mobilisation each battalion forms a fifth or depôt company, which performs the same duties as the depôt battalion does for the line regiments. They are recruited by picked men chosen throughout the army corps district. Unlike the rest of the infantry, they always stand in two ranks; and they are further distinguished by carrying a short rifle, and by their green tunics with black belts. The rifle battalions of the guards are mainly recruited from the rangers of the royal forests.

Cavalry.—The cavalry consists of 73 regiments, of which 10 are cuirassiers, 26 dragoons, 19 uhlans (or lancers), and 18 hussars. The cuirassiers and lancers are classed as heavy cavalry, dragoons and hussars as light cavalry. The cavalry of the guard numbers 8 regiments, of which 2 are cuirassiers, 2 dragoons, 3 uhlans, and 1 hussars, and are all carefully-picked men.

The organisation and establishments of all cavalry regiments are alike. In peace time they consist of 5 squadrons of 4 officers and 135 men each; in war the regiment takes the field with 4 squadrons of 150 men each, while the fifth squadron remains behind to form the depôt. The total strength of the 4 field squadrons is 677 men and 706 horses, and of the depôt squadron 267 men and 112 horses. The depôt includes an artificers' detachment of 54 men. A cavalry regiment thus requires a very small augmentation in war, and the field squadrons are completed at once from the fifth or depôt squadron, they sending to it their recruits and untrained or unserviceable horses. Owing to the terms of service usual in the cavalry, the actual proportion of "reservists" is much smaller than in the infantry, but they still far exceed the number required to complete the regiments, and accordingly are used to form the staff escort, field gendarmerie, field post and other special corps, and to furnish non-commissioned officers to the military train.

The Prussian cavalry first won its reputation under Frederick the Great, and his brilliant cavalry leaders Ziethen and Seydlitz. In the battles of Hohen Friedberg, Rossbach, and Zorndorf the cavalry decided the fortunes of the day, and gloriously verified their old motto—

Wenn alles wankt und schwankt
Dann wäge nicht und zähle nicht, dann d'rauf![1]

In recent campaigns they have more especially distinguished themselves by their intelligence and enterprise as scouts and outposts, covering the movements of their own armies with an impenetrable screen, while constantly feeling the enemy and reporting his movements. But their desperate charges at Mars la Tour and Rezonville, where they sacrificed themselves to check the enemy and give breathing-time to their own overmatched and exhausted infantry, will always be classed among the most heroic deeds in the annals of cavalry.

[1] "When fortunes are shaking and brave men are quaking,
Then stay not and weigh not, but down on the foe!"

The light cavalry (hussars and dragoons) are armed with breech-loading carbines and swords. In the heavy cavalry, 16 men per squadron carry carbines, the remainder pistols. The cuirassiers are armed with a long heavy sword (*Pallasch*), and wear a black cuirass weighing 16 ℔, and supposed to be bullet-proof. The uhlans carry a lance and the usual cavalry sword. The cuirassiers use saddlery of the "German" pattern, very cumbrous; the rest of the cavalry use the "Hungarian" saddle. On the whole, the Prussian cavalry ride slightly heavier than the corresponding troops in England. Great attention is paid to the selection of horses for the cavalry, and constant efforts are made, by the importation of valuable stallions and brood mares, to encourage the breeding of a suitable class of horses. The remounts are bought by commissions appointed for the purpose, and either sent direct to the regiments, or, if too young for work, to the remount depôts, where they are carefully broken. In war time the necessary augmentation is obtained partly by purchase in the market and partly by contracts previously made in peace time. If these measures are not sufficient, the Government has the power of compulsory purchase. For this purpose all the horses in the kingdom are registered and periodically inspected, and returns kept of those considered fit for military service. On the order for mobilisation the owners may be summoned to attend with their horses; these are inspected by a military board, who select as many as they require, and take possession at once; and a mixed board afterwards determines the compensation to be given to the owners.

Artillery.—The artillery of an army corps consists of two regiments of field artillery and a regiment of garrison artillery. One of the two field artillery regiments is organised in two divisions (*Abtheilung*) of four batteries (two heavy and two light) each; this furnishes the divisional artillery, one *Abtheilung* to each infantry division. The other consists of three divisions, two of field and one of horse artillery, of three batteries each; and furnishes the corps or reserve artillery, and the horse artillery, which is attached to the cavalry divisions. A field battery on peace footing has only 4 guns, with 114 men, 37 horses, and 2 waggons. In war time it has 6 guns, with 155 men, 125 horses, and 10 waggons. A horse battery has a war establishment of 6 guns, 154 men, 207 horses, and 10 waggons. On mobilisation a depôt division is formed for each army corps, consisting of 1 heavy, 1 light, and 1 horse battery, and a detachment of artificers. Further, a *Colonnen Abtheilung*, consisting of 9 ammunition columns (of which 5 carry artillery ammunition and 4 small-arm ammunition) is formed, and attached to the field artillery. The regiment of garrison artillery is composed of two divisions of four companies each, with a peace strength of 108, and a war strength of 209 men per company.[1] On mobilisation the field artillery is augmented by men of the reserve, and by men drawn from the garrison artillery regiment; the garrison artillery is principally reinforced from the artillery men in the landwehr. Sometimes the number of companies of garrison artillery is doubled. The Prussian artillery are armed with rifled breech-loading guns of cast steel, the heavy batteries with the 6-pounder gun, throwing a shell weighing about 15 ℔; the light batteries and horse artillery with the 4-pounder gun, throwing a 9 ℔ shell. The extreme range of these guns is about 5000 paces, but their effective range does not exceed 2500. A heavy battery carries 134 rounds per gun, a light battery 157 rounds; and the corps ammunition columns carry a further supply of about 100 rounds per gun.

[1] Four army corps have only a division of garrison artillery instead of a regiment

Pioneers.—Each army corps has a battalion of pioneers, of four companies, of which the first is the pontoon company, the second and third sapper companies, and the fourth the miner company. The men of each company are thoroughly instructed in their own special duties, but know also the duties of the other companies sufficiently to be able to assist if required.

The peace establishment of a company is 146 men. In war time the second sapper company remains behind, and forms three garrison companies, and a depôt company is also formed. The other three companies, augmented to a war strength of 218 men, take the field, and furnish the *personnel* for a light field bridge train or pontoon train, and an entrenching tool column, which also accompany the army corps. Further, four railway detachments and four field telegraph detachments are formed for the whole army. The railway detachments are formed from the railway battalion, which was organised immediately after the war of 1870-71, and is composed entirely of men trained to the various duties connected with railways, the officers and non-commissioned officers being qualified to act as railway managers, station-masters, &c. On mobilisation they receive their augmentation from reserve and landwehr men who are actually holding these positions on the various lines; and in war time they are charged with constructing, repairing, and working or destroying the lines in an enemy's country. The field telegraph detachments, in the same way, are trained in peace time to everything connected with telegraphy; in war they carry a light line, which they lay down as required, or work the existing lines.

Military Train.—The train is a mere skeleton in peace time. The battalion which is attached to each army corps is little but a cadre maintained for instructional purposes, and only numbers 240 men of all ranks, while the train soldiers attached to an army corps on war footing amount to 3500. The men are only subjected to six months' training, and by the constant renewal the number passed into the reserve is enormously increased; additional men are drawn from the cavalry reservists. In war time the train battalion is broken up altogether, and forms a number of separate detachments, viz., five provision columns, three ambulance detachments, a horse depôt, a field bakery column, and an escort squadron, to take charge of the five *Fuhr Park* columns which are organised of hired or requisitioned transport. Further, nearly 1000 train soldiers are sent to the various regiments (65 to an infantry regiment, 37 to a cavalry regiment) to drive the regimental baggage train, act as servants to staff and field officers; 800 to the artillery, principally as drivers, &c., for the ammunition columns; and 300 to the pioneers, for the pontoon and tool train; and 400 to the various administrative services. The whole of the transport in the Prussian service is departmental,—that is, is told off to certain special departments and duties, and is not available for general service. Thus the regiments have their regimental transport, the artillery their ammunition columns, the commissariat their provision columns, the medical department their field hospital and ambulance train, &c.

Depôt and Garrison Troops.—The *depôt troops* have been described in speaking of the field troops whom they have to feed. The *garrison* or *reserve troops* have no such immediate connection with the active army, and are almost entirely formed of the landwehr; they are specially intended for home defence and garrisoning the fortresses, but are also used to maintain communications, and relieve the active army of all detachments to its rear, and sometimes, as in the latter period of the Franco-Prussian war, are organised in divisions, and pushed forward to reinforce the active army. Every battalion district forms a landwehr battalion, and every army corps district forms a reserve rifle company, one or two reserve cavalry regiments, and three reserve batteries, from the landwehr men on its lists. The garrison companies of sappers and the garrison artillery have already been spoken of, and are more closely connected with the active army than the rest of the garrison troops. The officers for the landwehr and reserve regiments are supplied partly from the field troops, partly from one-year volunteers who have qualified, and non-commissioned officers of the army who have retired with the rank of landwehr officers, and partly from the half-pay list. In addition to the forces above named, a certain number of "garrison battalions" are sometimes formed from the surplus landwehr men, and some of the *Ersatz* reserve. This was done in the war of 1870–71 to relieve the depôt troops of the garrison duties which had devolved on them in consequence of the landwehr being sent to the front. The organisation and armament of the landwehr are generally similar to those of the field troops, but the infantry wear a broad flat-topped cap instead of the distinctive *Pickelhaube*.

The total war strength of the 14 army corps composing the Prussian army is

	Men.	Horses.	Guns.
Field Troops,	524,335	161,913	1428
Depôt Troops,	186,598	17,801	264
Garrison Troops,	200,552	26,047	246
	911,485	205,761	1938

The general organisation of the Prussian army remains the same in peace and war. The king is the Commander-in-Chief, and exercises his authority through the War Ministry. The War Ministry is divided into a number of departments, of which the principal are the Central Department, which includes the minister's office; the General War Department, which deals with all questions of organisation, mobilisation, quartering, training, &c., and all strategical and purely military questions; and the Military Finance Department, which deals with all questions of pay clothing, equipment, and supply. Directly under the king and the War Minister come the commanders of the army corps districts into which the kingdom is divided. In peace time each corps command comprises two divisions, a rifle battalion, a brigade of artillery, and a battalion of pioneers and of train; each division consists of two infantry brigades and one cavalry brigade; each infantry brigade consists of two line regiments (exceptionally three) and one or two landwehr regiments; each cavalry brigade of two or three cavalry regiments. On the order for mobilisation the regiments are completed to war strength, the depôts formed, and the landwehr or garrison troops organised. A few slight alterations are made to equalise the army corps (the details of the war strength of which have been already given) to a uniform strength of 25 battalions, and a portion of the cavalry and one or two batteries of horse artillery are withdrawn from each corps to form separate cavalry divisions. The active army then takes the field, with the same organisation and under the same officers, corps and divisional commanders, brigadiers, staff, &c., that they have been accustomed to in peace.

Mobilisation. The instructions for mobilisation are minute and complete. Every year a "paper mobilisation" scheme is drawn up, showing the number of men and officers required to place every corps and detachment on war footing, and whence these would be obtained, and showing also on what duties the officers and men actually present would be employed. This scheme is completed at the army corps headquarters, and after revision by the War Minister, is approved and promulgated. Every individual thus knows beforehand what would be his duties in case of war, and the pith of the system lies in two short sentences in the "Secret Instructions"—"Every person in authority should know in peace what will be required of him on the order to mobilise, and must expect no further orders. All orders which have to be issued are to be kept ready in peace." The steps to be taken on mobilisation are detailed day for day. On the first day the War Ministry acquaints the commanders of army corps and principal military authorities, and also telegraphs direct to the commanders of landwehr battalion districts, to summon the reserves. On the second and third days the landwehr commanders complete the written summons, which are kept always ready, notifying to each man when and where he is to join; and these are sent out by aid of the civil authorities. The reserves for the field troops are called in first, the landwehr men one or two days later. On the fourth and fifth days the reserve men assemble, and are forwarded to their regiments, whence a few officers and non-commissioned officers have been sent to take charge of them. Meanwhile the regiments have formed their depôts, drawn the reserve clothing and equipment from their stores, and get everything in readiness to receive their augmentation men. Most regiments are complete and ready to take the field by the seventh day. As soon as the reserve men have all been despatched, the landwehr men are collected, and equipped from the stores at the headquarters of the battalion district. The landwehr battalions are mostly completed about the eighth day. The reserve cavalry and some of the administrative departments take a little longer, but in 1870 the mobilisation was so far completed that the movement of the army corps to the front could be commenced on the ninth day. The commanders of army corps, divisions, &c., accompany their commands, and are replaced in their local commands by temporary (*stellvertretende*) officials.

Appointment and Promotion of Officers.—The Prussian army draws its officers mainly from the *Kleinadel* or lesser nobility, corresponding to the country gentry of England. Promotions from the ranks are very rare, and generally carry with them retirement or transfer to the landwehr. A certain number of young men of middle class obtain commissions, but principally in the scientific corps or in the landwehr. First appointments are obtained either from the cadet schools or by entering the ranks as *avantageurs*. More than one-half the officers enter by the latter system. A young man seeking a commission obtains a nomination from the colonel of a regiment, which admits him to serve as a private, but with recognition of his being a candidate for the rank of officer, and as such he is called an *avantageur*. He is usually required to sleep and mess with the privates in their barrack-room for the first two months; after that he has more liberty given to him, and is sometimes received at the officers' table. After six months' service, and passing an examination in the subjects of a liberal education, he becomes qualified for promotion to the rank of *Porte épée Fähnrich* (swordknot ensign), a sort of intermediate position between the commissioned and non-commissioned ranks. After six months' further service in this rank he is sent to a military school for a ten months' course of instruction, at the close of which he is required to pass an examination in purely military subjects; and then becomes qualified for a commission, subject to being accepted by the officers of the regiment as worthy of admission among their number. The career of those youths who enter from the cadet schools does not differ materially from the above. The great majority enter as "avantageurs," and serve their time as already described, only passing the first or ensign's examination before they enter, and being appointed to regiments by the king, instead of obtaining nominations from the colonels. A certain number who pass through the higher classes of the cadet school enter the army at once as *Porte épée Fähnrich*, and serve their probation in that rank only; while a very few, the *selecta*, who take the highest honours, are given commissions direct. Promotion in the army depends solely on the will of the king, but in the main is governed by seniority; but exceptions are made in favour of officers of the general staff, who commonly receive a step of rank on completing a term of duty in any staff appointment, aide-de-camps of higher generals, instructors at the cadet and war schools, and officers who have specially distinguished themselves in the field. As a rule, promotion to the rank of captain is by seniority in the regiment, but above that rank by seniority throughout that branch, or by selection. Officers are also freely transferred from one branch to another; thus, after the battle of Gravelotte, the command of the rifle battalion of the guard was given to an engineer officer. Especial attention is bestowed on the selection of officers for the general staff. These are generally taken from those who have passed through the War Academy at Berlin, the highest educational establishment in the Prussian army. Candidates for admission to this academy must have served at least three years with their regiments, must pass a qualifying examination, and must be favourably reported upon by their commanders. The course lasts three years, and those officers who give proof of sufficient abilities are afterwards employed for a time on various military works, under the immediate supervision of the chief of the staff, who thus acquires a personal knowledge of the character and abilities of all staff officers. Occasionally officers specially recommended are taken direct from their regiments; but they are always tested by the chief of the staff before receiving appointments. The anxious care bestowed on the selection of officers for these important duties has borne its fruit: the Prussian staff has made itself a world-wide reputation, and to it and to the genius of its chief, Von Moltke, may be awarded a large share in the success of the Prussian arms. The army is equally fortunate in its corps of officers generally,—men who unite the power of command and the high qualities of an aristocracy with the most thorough knowledge of their profession and devotion to it. The pay of the Prussian officers in the lower ranks is small, usually about half that of the corresponding ranks in the English army, and lower than in most of the Continental ones; but the higher ranks are well paid, probably better than in any other army, if the relative value of money and cost of living are considered.

The strength of the Prussian system lies in its close localisation and permanent organisation. The first secures the strongest possible *esprit de corps* and the greatest simplicity and speed in mobilising; the second that familiarity of every individual with his position, duties, and surroundings, which is essential to the smooth working of so complicated a machine as a great national army. It is to these, coupled with the careful training, the subordination of everything to the army, and the ever-watchful foresight with which every contingency is studied and provided for beforehand, that the remarkable successes of the Prussian armies are to be attributed, rather than to the excellence of the material or to the special military qualities of the nation. Physically the Prussian soldier is not much if at all above the average. It is true that the guards and some of the regiments from the northern provinces are exceptionally fine, but the army is very unequal, and men of practical experience have declared the German, as a rule, to be not equal in power or in endurance to the Frenchman.[1] In quick aptitude for war the Frenchman has always had the advantage. Generally, where the two have met on equal terms the Frenchman has been victorious; and even through the disasters of the late war, impartial witnesses have asserted that, man for man, the Frenchman was the better. But such natural qualities as the Prussian soldier possesses have been developed to the utmost by a civil education superior to that of any other nation, and by a military training, physical as well as mental, which may well serve as a model to all armies. He is docile, temperate, simple in his tastes and aspirations; and though not so demonstrative as his French neighbour, and with no fanatical enthusiasm, has a deep love of his country and loyalty to his king. If not easily excited to heroism, neither is he easily discouraged. No Englishman can forget that memorable march, when the Prussian army, unshaken by the disaster of Ligny, undeterred by the difficulties of the road or the enemy thundering in their rear, pushed on with indomitable energy through all obstructions to succour their hard-pressed allies at Waterloo. The Prussian army, more than any other, is the *élite* of a nation; and so long as the nation consents to submit to the burdens of her present military system, and her affairs are guided by chiefs as able and far-seeing as her present rulers, she will hardly forfeit the position she has won as the first military power of Europe.

Saxon Army.

The kingdom of Saxony, with a population of $2\frac{1}{2}$ millions, furnishes one strong army corps (29 battalions of infantry and 6 regiments of cavalry) to the German army. The Saxons were long renowned as a warlike race, and played a prominent part in all the wars of Northern Europe; and her princes twice mounted the throne of Poland. At the outbreak of the wars of the French Revolution she maintained an army of over 30,000 men, and at first sided with Prussia. After the disasters of Jena and Auerstadt she allied herself with France, and for some years furnished a contingent to the armies of Napoleon, who in return recognised her elector as king, and largely increased his territories. The newly-made king remained faithful to Napoleon even in his reverses; but the army was too German in feeling to fight willingly under the French flag. In 1809 they did not distinguish themselves at Wagram, and their defection at Leipsic contributed not a little to the results of that bloody day. After the peace the king retained his title, though shorn of a great part of his dominions, and the army was reconstituted on a smaller scale. In 1866 Saxony sided with Austria, and her army shared in the disasters of that brief campaign and the crowning defeat at Koniggratz. At the close of the war she was compelled to ally herself with Prussia, and, as part of the North German Confederation, to place her military forces at the disposal of the Prussian monarch. In 1870 and 1871 her troops, under the command of the crown prince (now king) of Saxony, formed the 12th corps of the great German army, and bore their share in the battles of Gravelotte and Sedan and in the siege of Paris. Her army is organised in every respect as a Prussian army corps, and is under the command in chief of the German emperor, who, in concert with the king of Saxony, names the officers for the higher commands. She retains, however, her separate War Ministry, budget, &c.; and appointments and promotion to all but the highest commands are made by the king of Saxony. The Saxon troops fought well in the late war between Germany and France. In appearance they are smarter than most of the German troops, and have a certain resemblance to the English; but their uniform and equipment are assimilated in all respects to the Prussians.

[1] See the opinion of Mr Brassey, the eminent contractor, quoted in his *Life*.

Bavarian Army.

The kingdom of Bavaria, with a population of a little under five millions, furnishes two army corps to the German army. Like Saxony, Bavaria, originally an electorate, was enlarged and made into a kingdom by Napoleon. Under the command of Marshal Wrede, a distinguished Bavarian, her troops fought side by side with the French through the campaigns of 1805 to 1812, but in 1813 she seceded and joined the Alliance, and attempted to intercept the French on their retreat from Leipsic. Napoleon, however, inflicted a severe defeat on his old general at Hanau, and opened his road to France. In 1866 the Bavarians took part against Prussia, but owing to their dilatoriness in taking the field, the Prussians were able to beat them in detail, nor did their generals or troops shine in this war. In 1870, however, they joined their former enemy in the war against France, and bore their full share in the glories and losses of the campaign, the second Bavarian corps having suffered more heavily than any but the third Prussian corps. Her army has now been assimilated to that of Prussia in most respects, but still retains certain distinctive peculiarities of dress and equipment, such as her old light blue uniform, and helmet with black plume.

Würtemberg Army.

Lastly, Würtemberg, with a population of a little under two millions, furnishes one army corps, organised, clothed, and equipped in all respects like the Prussian army. Like the Bavarians, the Würtembergers fought against the Prussians in 1866, but in 1870 made common cause with them against the French, and by the convention entered into the following year, placed their army permanently under the command of the Prussian king as emperor. The emperor nominates to the highest commands, but the king of Würtemberg retains the nomination and appointment of officers in the lower grades.

The total military forces of the German empire (war strength) are shown in the following table :—

Field Troops.	Officers and Men.	Horses.	Guns.
Infantry—148 Regiments	453,731	15,540	...
,, — 26 Rifle Battalions	26,756	754	...
Cavalry—93 Regiments	62,234	63,932	..
Artillery—18½ Brigades	68,321	64,350	1800
Engineers—18 Battalions	15,457	3,221	...
Train—18 Battalions	36,315	43,386	...
Staff and Administration	14,029	13,404	...
Total Field Troops	676,843	204,587	1800
Depôt Troops	242,979	18,989	342
Garrison Troops[1]	431,869	34,522	318
Grand Total	1,251,691	258,098	2,460

But even this does not represent the entire force at the disposal of the empire in war. More than 100,000 trained soldiers still remain available; while the *Ersatz* reserve of men untrained, but registered, and ready to be drafted into the depôts, raises her total to over two millions of men.

French Army.

From the earliest times the inhabitants of Gaul were distinguished for bravery and enterprise. First as enemies and afterwards as subjects and auxiliaries, they played an important part in the great wars of Rome; and though they yielded to the irruption of the Franks, the admixture of races seemed only to heighten the warlike spirit of the nation. Under Charlemagne, and, later, in the Crusades, and under Philip Augustus and St Louis, the chivalry of France especially distinguished itself. The excessive power and independence of the great vassals, however, long prevented the formation of any permanent national force, and made France a prey to intestine wars and foreign invasions. Charles VII. availed himself of the lull which followed the final expulsion of the English in the middle of the 15th century to organise his *compagnies d'ordonnance*, and thus laid the foundation of a national standing army. But the armies that followed the kings in their wars still consisted mainly of foreign mercenaries, hired for the occasion; and the creations of Charles and his successors fell to pieces during the religious wars. Louvois, War Minister of Louis XIV., was the true creator of the French royal army. On his accession to power, the king's guards, some squadrons of *gendarmerie*, and a few infantry regiments (afterwards distinguished as the "old"), constituted the whole of the standing army. All other forces had to be created at the outbreak of a war, being usually raised under contracts allotted to generals and others. Louvois first transferred the army from the hands of contractors and speculators to those of the king. He abolished the *arrière-ban*, and substituted a money tax for the liability to service, thereby obtaining funds for the maintenance of a regular army. In 1672, after ten years of his administration, Louis XIV. was able to take the field with a force of 91,000 infantry, 28,000 cavalry, and 97 guns, all permanently organised troops, the largest national army that had yet been seen; and six years later the military forces of France had been raised to nearly 280,000 men. The last half of the 17th century is a brilliant period in the annals of the French armies. Organised by Louvois, animated by the presence of the great king, and led by Condé, Turenne, Luxembourg, Catinat, and Vendome, they made head against coalitions which embraced nearly all the powers of Europe, and won a series of victories that extended the bounds of France, and made her for a time the first military nation of Europe. But after the death of Louis XIV. the French army gradually deteriorated. In the Seven Years' War it was disgracefully defeated. Under the reign of Louis XV. confusion and maladministration prevailed everywhere, and the highest idea of military art was to copy servilely every minute detail of the Prussian army. The higher officers, usually nobles about the court, seldom went near their regiments; and Madame de Genlis relates how, when young courtiers departed to join their regiments for a few weeks' duty, the ladies of the court decked them with scarfs and favours, as if proceeding on a distant and perilous expedition.

Under Louis XVI. the army improved somewhat; the American war and the successes of Lafayette and Rochambeau revived a more warlike spirit; instruction was more carefully attended to, a good system of drill and tactics was elaborated at the camp of St Omer, and attempts made to reform the administration. But the Revolution broke over France in the midst of these attempts at reorganisation; the old royalist army disappeared with the monarchy, and was merged in that revolutionary army which under a new flag was destined to raise the military fame of France to its greatest height.

If Louvois was the creator of the royal army, Carnot was so of the revolutionary army. At the outbreak of the Revolution the royal army consisted of 105 infantry regiments of 2 battalions each, 14 rifle battalions, 7 regiments of artillery, and 62 regiments of cavalry, numbering about 173,000 in all, but capable of augmentation on war strength to 210,000. To this might be added a provincial or militia force of about 60,000, but nominal rather than

[1] Of these garrison troops, about 165,000 infantry, 10,000 cavalry, and 156 guns are available as reinforcements to the field troops.

real. At the very outset it was deemed necessary to reorganise and augment this army. Voluntary enlistment under the system of *racoleurs* or "bringers," by which the army had hitherto been fed, was found insufficient. "Compulsory service" was proposed in 1789, but rejected as "contrary to the liberty of the citizen." An appeal was then made to the patriotism of the nation, and 200 battalions of volunteers were enrolled; but though many presented themselves, and these volunteers contained much of the best blood and highest intelligence of France, the numbers fell far short of the expectations, and the proportion that reached the frontier was small. In the winter of 1792–3 the French armies, notwithstanding the unexpected successes of the preceding campaign, seemed on the point of dissolving altogether, and the Convention was driven to order a compulsory levy of 300,000 men.

To eradicate the royalist element from the army, the old regiments were broken up and amalgamated by battalions with the volunteers; and the name even of "regiment" was abolished. Promotions were made, not by seniority of rank, but length of service; thus an old sergeant succeeded to the command of a regiment over the heads of all the captains. In August 1793 the affairs of France were at their lowest ebb. Its armies had been driven from the Rhine and out of Belgium, and a dangerous insurrection had broken out in La Vendée. The compulsory levy, slowly and imperfectly carried out, had not yielded the full number; and those that were obtained deserted by hundreds. The nominal strength amounted in all to 480,000 men, but one army with a paper strength of 90,000 had really only 33,000 in the ranks, and the others were little better. Under the new system of promotion commands changed almost daily, and fell into the hands of men who had never before been entrusted with more than a section; and confusion reigned everywhere.

Such was the position when Carnot, then a captain of engineers, was called to the Ministry of War. A few days later a levy *en masse* of all the male population between the ages of 18 and 25 was ordered, and was carried out with more method and success than former levies. The muster-rolls of the armies filled rapidly, and by the end of the year the effective force had risen to 770,000. The amalgamation of the old army and the volunteers, which had been commenced, but imperfectly carried out, was effected on a different and more thorough principle; the white uniform distinctive of the old days of royalty was abolished, the infantry organised in demi-brigades of three battalions (usually one of the old army to two of volunteers), and the men and cadres intermixed within the demi-brigade. A permanent organisation in divisions, composed of all arms, was introduced, and able officers selected for the commands. Jourdan, Hoche, Pichegru, Kleber, Moreau, were at the head of the armies of the republic. Arsenals and manufactories of warlike stores were created, schools of instruction were established; the republican forces were transformed from hordes to armies, well disciplined, organised, and equipped. The enemies of France were defeated at all points; and in tracing the plan for the campaign of 1794 Carnot showed that his genius shone in strategy as much as in administration. "Twenty-seven victories, of which 8 in pitched battles, 120 combats; 80,000 enemies *hors de combat*; 91,000 taken prisoners; 116 fortresses or important towns taken, 36 of them after siege or blockade; 230 forts or redoubts carried; 3800 guns, 70,000 muskets, 1900 millions of powder, and 90 colours captured;"—such was the account Carnot was able to give of eighteen months of office; and at the close he returned to his duty as a simple major of engineers. And even this did not do justice to all he had effected. Himself of an almost Roman type of character,—severe, but a true patriot and republican,—he had succeeded in infusing much of his own spirit into the army; he had given it not merely discipline and organisation, but honour and soldierly feeling. When Moreau promulgated to his army the decree of the Convention, which forbade them to give quarter to any Englishman or Hanoverian, he added, in general orders, "I have too high an opinion of French honour to believe that such an instruction will be obeyed;"—and he was right.

In the year 1796 Napoleon appeared on the scene, and by a series of brilliant victories enlarged the frontiers of France and secured a glorious peace. But the exhaustion of years of continuous warfare had made itself felt: the armies were reduced to mere skeletons, and no sufficient means existed of replenishing them, till in 1798 the *conscription* was introduced. From that time there was never a dearth of men: the whole male population of France was practically at her ruler's disposal; and Napoleon had full scope for his genius in organising these masses. His principal improvements were effected in the interval between the peace of Amiens and the war with the third coalition, while threatening the invasion of England. His armies were collected in large camps on the coasts of the Channel, and there received that organisation which, with minor variations, they retained during all his campaigns, and which has since been copied by all European nations. The *divisions*, as organised by Carnot, consisted usually of two brigades (twelve battalions) of infantry, two regiments of cavalry, and two or three batteries of artillery. This was a great improvement on former organisation, and worked well in the comparatively small armies which then took the field. But in large armies of 150,000 men and upwards the number of isolated commands was too great. Further, it had been found by experience that the very completeness of the divisional organisation—each division forming a miniature army complete in all branches—tended to excessive independence of action on the part of the divisional commanders. Napoleon therefore grouped two or three divisions into *corps d'armée*, commanded by marshals. He withdrew the whole of the cavalry and a portion of the artillery from the divisions, and with the light cavalry and batteries so obtained formed a reserve corps under the immediate orders of the corps commander; while he kept the whole of the heavy cavalry, amassed in cavalry divisions, his guards, and a certain proportion of artillery, in his own hands, as a reserve to the whole army. Thus was organised that "grande armée" which immortalised itself at Ulm, Austerlitz, Jena, Friedland, Wagram, and Borodino; and after planting the tricolor on every capital of Europe, perished at last in the snows of Russia.

The frightful expenditure of life during Napoleon's wars almost drained France of her manhood, and his frequent calls on the country made the name of the conscription detested. One of the first acts of the Restoration was to abolish it, and return to voluntary enlistment; but it was soon evident that this means of recruiting no longer sufficed, and within three years compulsory service had to be again resorted to. In 1818 the annual contingent was fixed at 40,000, and the period of service at six years; in 1824 the contingent was increased to 60,000, and in 1832 to 80,000. Of this, however, a part only, according to the requirements of the service, were enrolled; the remainder were sent home on leave or furlough. Up to 1855 certain exemptions were authorised, and substitution or exchange of lots amongst young men who had drawn was permitted, but the individual drawn was obliged either to serve personally or find a substitute. In 1855 the law of "dotation" or exemption by payment was passed, and put an end to personal substitution. The state now undertook to provide substitutes for all who paid a fixed sum, and did so by high bounties to volunteers or to soldiers for re-engaging. Although the price of exemption was fixed as high as £92, on an average 23,000 were claimed annually, and in 1859 as many as 42,000 were granted. Thus gradually the conscription became rather subsidiary to voluntary enlistment, and in 1866, out of a total establishment of 400,000, only 120,000 were conscripts. Changes had also taken place in the constitution of the army. On the Restoration its numbers were reduced to 150,000, the old regiments broken up and recast, and a royal guard created in place of the old imperial one. When the revolution of July 1830 had driven Charles X. from his throne, the royal guard, which had made itself peculiarly obnoxious, was dissolved; and under Louis Philippe's reign the army was augmented to about 240,000 with the colours. Under the Provisional Government of 1848 it was further increased, and in 1854, when France allied herself with England against Russia, the army was raised to 500,000 men. The imperial guard was re-created, and every effort made to revive the old Napoleonic traditions in the army. In 1859 Napoleon III. took the field as the champion and ally of Italy, and the victories of Montebello, Magenta, and Solferino raised the reputation of the army to the highest pitch, and for a time made France the arbiter of Europe. But the campaign of 1866 suddenly made the world aware that a rival military power had arisen, which was prepared to dispute that supremacy. From this time a trial of strength between France and Prussia was looked forward to as inevitable, and both sides prepared for the coming struggle. Niel, the then War Minister of France, saw clearly that the organisation which had with difficulty maintained 150,000 men in Italy, was no match for that which had within a month thrown 250,000 into the very heart of Austria, while waging a successful war on the Maine against Bavaria and her allies. In 1867, therefore, he brought forward a measure for the reorganisation of the army, by which he calculated to raise the military force to 800,000 men—half of them with the colours and half in reserve—besides forming a separate army for home defence in case of need. It is not necessary to dwell on the law of 1868, for it remained but two years in real operation. To complete Niel's scheme many years were required; but Niel himself died within a year, and the next year saw the French army annihilated, or existing only as prisoners of war in Prussia.

At the outbreak of the great Franco-German war the French field troops consisted of 368 battalions, 252 squadrons, and 984 guns. The strength of the entire army on peace footing was 393,000 men; on war footing, 567,000. The forces immediately available for the war on the Rhine were estimated at 350,000, but they actually fell short of 300,000. They formed 8 *corps d'armée*, each composed of from two to four infantry divisions and one cavalry division,—making a total of 26 infantry divisions of 13 battalions each, 11 cavalry divisions of from 4 to 7 regiments each, and 756 guns. Within seven weeks the whole of this army, with trifling exceptions, was either captive in Germany or hopelessly shut up in Metz. But the spirit of the nation rose to the occasion, and though, as the result proved, extemporised armies can do little against veteran ones, the efforts of the people and the creative energy of her rulers will always command admiration. The next year's contingent of recruits was called out and hastily trained. Fourth battalions were formed from the depôt *cadres*, and organised into *régiments de marche*. The *gardes mobiles* were mobilised, and by successive decrees and under various names nearly all the manhood of the country called to arms.

The regular troops raised as *régiments de marche*, &c., amounted to 213,000 infantry, 12,000 cavalry, and 10,000 artillery. The *garde mobile* exceeded 300,000, and the mobilised National Guard exceeded 1,100,000—of whom about 180,000 were actually in the field and 250,000 in Paris; the remainder in camps or depôts. Altogether the new formations amounted to nearly 1,700,000, and if to that be added the army existing at the beginning of the war, the total forces developed by France during the struggle reach the enormous amount of 2¼ millions.

The reorganisation of the army took precedence of all other questions when the conclusion of peace with Germany and the suppression of the communist revolt gave rest once more to the country. By the law of recruiting of 1872 compulsory personal service was introduced, and substitution or purchase of exemption was abolished. The period of liability was fixed at twenty years—five years of the time to be passed in the regular army, four years in the reserve of the regular army, five years in the territorial army, and six in the reserve of the territorial army. The annual contingent is not a fixed one, or determined by the actual requirements of the army, but includes all capable of bearing arms; certain exemptions in favour of only sons of widows, sole supports of families, teachers, and theological students excepted. But as the peace establishment, governed by financial considerations, would not admit of retaining the whole of five years' contingents with the colours, it was provided that the contingent should be divided by lot into two classes, the first to serve the full five years, the second to be sent home after six months' or a year's training. One-year volunteers are admitted on conditions similar to those existing in Prussia. In the calculations on which the law was based it was estimated that about 300,000 annually came of age, of whom about one-half would be rejected as unfit, or exempted on personal or family grounds. Of the remaining 150,000, one-half would serve for the full five years, the remainder for six months or a year only; and the peace army would thus comprise four yearly contingents of 75,000 and one of 150,000. Deducting the one-year volunteers, a percentage for casualties, and the men of the fifth year who would usually be sent home on furlough, the remaining four classes give about 350,000; and adding 120,000 to this for the permanent part of the army, the total of 470,000, being the proposed peace establishment, is obtained.

The organisation of the army was made the subject of a separate law passed in 1873. The land forces are divided into the *active army* and the *territorial army* or landwehr. The active army consists of 18 *corps d'armée*, besides a special corps for service in Algeria; each corps is composed of two divisions of infantry, a brigade of cavalry, a brigade of artillery, a battalion of engineers, and a squadron of the military train, and retains its organisation permanently in peace and war. The total strength of an army corps is about 40,000 of all ranks, or about 30,000 combatants, with 108 guns. The country is divided into 18 "regions," and each region has always a corps stationed within it, and is provided with magazines and stores of all sorts required to equip the corps for the field, and to furnish out the depôt and territorial army as well. The army corps are not permanently localised, but are moved from district to district; and on mobilisation they draw their reserves and stores from the districts in which they happen to be stationed. Recruiting is partly general and partly regional; those recruits who are drawn for five years being distributed throughout the army, while those who have to serve one year only are attached to the corps stationed in their district. For recruiting and for purposes of mobilisation the "regions" are subdivided, each subdivision comprising one or more recruiting offices, in which the recruiting lists, as well as the registers of all furlough or reserve men, and men belonging to the territorial army, are kept. As a rule, each such office corresponds to a battalion of the line, and has from 2000 to 3000 names on its books. The general commanding an army corps has under his orders all military forces (territorial or reserve troops as well as active) and establishments within the district. He is assisted by a staff divided into two sections, of which the first or active part accompanies the active army on mobilisation, while the second or territorial part is permanently attached to the district, and is specially charged with recruiting, remounts, and all local affairs, and remains stationary on mobilisation. No general can hold the command of an army corps for more than four years. At the head of each subdivisional recruiting office is placed an officer of rank corresponding closely to the landwehr battalion district commander in Prussia. All soldiers of the active army, reserves, or territorial forces who are living at their homes, under whatever conditions, and are domiciled within his subdivision, are under his orders. The *territorial army* exists in cadre only in peace time; but its cadres are always formed and its organisation established. It is officered by retired or half-pay officers and one-year volunteers, or old non-commissioned officers who, on completing their army service, have qualified as officers of the territorial army. The reserve of the territorial army is not called out except in case of absolute necessity, and then by classes beginning with the youngest.

The military forces of France under the new laws are estimated as follows, allowance being made for casualties:—

Active army (5 classes),	705,000
Reserve of active army (4 classes),	510,000
Temporary exemptions,	141,000
Permanent part of army,	120,000
Total of active forces,	1,476,000
Territorial army—	
5 classes, organised,	582,000
6 classes (reserve), not organised,	626,000
Total,	1,208,000

In estimating the numbers available for the active army, however, deductions must be made for the last class of recruits (150,000) and the temporary exempts (141,000), who are untrained, and for a number of non-effectives, estimated at from 150,000 to 200,000, which would reduce the total to about 1,000,000. And further, in comparing these numbers with those of the German army, it must be borne in mind that, whereas almost every man on the German lists has received his three years' training, nearly one-half of the French army is composed of men who have served a year or less with the colours. The peace establishment of the French army is fixed at 450,000; the war establishment of the field army, exclusive of depôts and garrison troops, at 780,000.

The French field army now (1874) numbers 496 battalions of infantry, 380 squadrons of cavalry, and 380 batteries; being 126 battalions, 56 squadrons, and 158 batteries in excess of its strength at the outbreak of the war of 1870. The imperial guard has been broken up, and its soldiers distributed throughout the army. Of the creations of the war, the mobilised national guard has been disarmed and dissolved; the *gardes-mobiles* sent home, but inscribed as reserve of the army; and the *régiments de marche* have been partly disbanded, partly amalgamated with the regiments from whose depôts they had been formed. The *infantry* consists of 144 line regiments, each of 3 active and 1 depôt battalion; 4 regiments of Zouaves and 3 of Turcos, each of 4 field battalions and a weak depôt; 36 rifle battalions (*chasseurs*) of 6 field and 2 depôt companies each; a foreign regiment; and 3 battalions of Algerian light infantry ("Zephyrs"). The peace establishment of a regiment of the line is about 2000; the total strength of the infantry, 298,000.

The *cavalry* consists of 12 regiments of cuirassiers, 26 of dragoons, 12 of hussars, 20 of *chasseurs-à-cheval*, 4 of *chasseurs d'Afrique*, and 3 of Spahis. Notwithstanding the reputation which the Prussian uhlans had acquired in the war, one of the first acts of the French Government was to abolish the lance, and transform the old lancer regiments into dragoons. Each regiment consists of 5 squadrons, 4 of them field and 1 depôt, and numbers about 900 men and 800 horses; the total strength of the cavalry is 58,000 men and 50,000 horses.

The *artillery* consists of 38 regiments, of which 19 have each 10 field batteries, and 19 have 6 field and 4 horse-artillery batteries. The battery has six guns. The artillery further comprises 30 garrison batteries, a regiment of pontoniers, 15 companies of artificers, and 2 regiments of artillery train. The total peace strength of the artillery is 45,000 men and 24,000 horses.

The *engineers* consist of a staff of 462 officers and 570 men, and 3 regiments, forming 48 companies of sappers, 6 of miners, and 3 of engineer train. These are ultimately to be formed into 19 independent batteries.

The key to the French military character, its strength and its weakness, is well given by one of their own writers, Blondel:—"We love the roll of the drum, the coquetry of uniform, the roar and tumult of battle; but *obedience* is burdensome to us,—it is strange to our character and to our time. The ruling spirit of criticism is injurious to discipline, and too often the study of duties is overlooked in the study of rights. The *warlike* spirit of the ancient Gauls has remained as an inheritance to their descendants; but notwithstanding the fame which our arms have achieved in all epochs of our history, the true *military* spirit is rare in France." This warlike spirit, which the French possess perhaps beyond any other nation, is a matter of race and temperament; the military spirit is the result of a nation's training, and in that the French have been singularly unfortunate. From the time that the Franks, fourteen centuries ago, subdued the original Gallic or Celtic population of France, the nation was divided into two sharply-defined classes, the conquerors and conquered. The former alone were warriors and free; the latter were mere serfs condemned to till the ground and labour. The Frank chivalry was renowned through Europe; but the peasant was perhaps the most abject of his class. This it is that explains the difference between the helpless crowds of footmen that followed the French nobility to battle, and seemed only brought there to be slaughtered, and the sturdy British archers who formed so important an element of strength in the English armies. Hence also the difficulty found in raising an efficient national infantry; as their own king, Francis I., says in his manifesto to the German princes—"We have in our land no foot soldiers, because our ancestors trained our peasantry to agriculture rather than war." Even in the days of Louis XIV. and Louis XV. the foreign troops amounted to one-third or one-fourth of the army, and formed distinct corps, usually receiving higher pay. The brilliant feats of arms that gave such *préstige* to the French name were mostly performed by he gay and gallant aristocracy. It was the "Maison du Roi who seized Valenciennes in broad day by a *coup de main*, who decided the battle at Steinkirk, who broke the column of Fontenoy. The common soldiers were *canaille*, separated by an infinite gulf from their officers. All this was changed by the great Revolution. The former slaves became masters, but they had had no training to qualify them for freedom, and that "law-abiding" spirit that marks the German and Anglo-Saxon races was wanting in them. The old warlike spirit was revived and stimulated by the enthusiasm of newly-acquired liberty; and Napoleon knew how to turn to account the admirable material he found to hand. But while he knew better than any one how to stimulate this martial ardour, he did nothing to raise the tone of the army or inculcate a sense of duty. Glory and rewards were the two levers of action he trusted to; and the extravagant "dotations" bestowed on all occasions on his followers did much to create that mercenary spirit that has ever since tainted the army. To the French soldier war means glory, promotion, plunder: if these are not immediately attainable, he becomes impatient, and blames his leaders. Physically the Frenchman is smaller than the German or Englishman, but is usually better formed about the hips and lower limbs, more active, and more enduring. Mr Brassey, the great contractor, ranks him next after the Englishman and before the German for power of work. Of a gay, volatile, excitable temperament, he has always distinguished himself by impetuosity in attack, but has not shown equal constancy and perseverance in maintaining the contest. A brilliant offensive brings out all his best qualities; he has a natural aptitude for war, a quick eye to seize the situation, and the *furia Francese* has become proverbial; but on the defensive he becomes impatient and discouraged, and he is soon demoralised by defeat and disaster. It is then, when discipline and duty alone hold men together, that the want of the true *military* spirit makes itself felt, and till this is created in France, even her most brilliant successes must be uncertain and transitory.

Austrian Army.

The imperial army of Austria may be said to date from the Thirty Years' War. Long before that, Maximilian I. had established a corps of "kyrisser" (original of the modern cuirassiers), and taken into his pay a considerable force of "landsknechts," the early German infantry. But the latter were companies engaged for the war only, and disbanded at its termination; and it was not till the reign of Rudolph II. (about 1600) that any permanent regiments were formed. Even these can hardly be counted as belonging to the imperial army, for the men composing them were only indirectly subject to the sovereign, and really obeyed their own chiefs, who could transfer their services to other powers. It was Wallenstein who first raised a distinctly imperial army of soldiers owing no duty but to the sovereign; and it was the suspicion that he intended to use this army, which was actually raised largely at his own expense, to further his own ends, that led to his assassination. From that time the regiments belonged no longer to their colonels, but to the emperor; and the oldest regiments in the present Austrian army date from the Thirty Years' War. At the close of the war Austria had 19 infantry and 7 cavalry (6 cuirassier, 1 dragoon) regiments. Half a century later her forces had increased to 40 regiments of infantry and the same of cavalry; and in 1809, when she put forth her whole strength for the great struggle with Napoleon, she had 61 infantry regiments (46 German and 15 Hungarian) and 45 of cavalry. Up to the beginning of this century, her armies were recruited almost entirely by voluntary enlistment; but, like all the other powers, she was compelled to follow the example of France, and have recourse to the conscription during the great Revolutionary wars. During the half-century which intervened between the final overthrow of Napoleon and her struggle with Prussia for supremacy in Germany, various minor alterations were introduced, but in the main her military system remained as it was at the close of the great war. The conscription continued in force, the period of service being fixed at ten years, eight of them in the ranks and two in the reserve; unlimited furloughs, however, were largely granted, and the actual service in the ranks seldom exceeded six years, and was often reduced to two or three in the infantry. The disastrous war with Prussia in 1866, and the new constitution finally granted in 1867, led to an entire revision of her military institutions in the following year, and her present organisation is based on the law of 1868.

The armed forces of Austria consist of the *standing army*, which in peace time, on a reduced footing, serves as a school for training the nation to arms, and in war time, completed by its reserves, forms the field army; the *landwehr*, which in war time acts as a support to the field army and provides for home defence; the *Ersatz reserve*, from which casualties in the field army are replaced; and the *landsturm*, a national levy only called out to resist invasion. The war establishment of the standing army is fixed at 800,000; the peace establishment varies, being governed by financial considerations, but is usually about 250,000.

Every male citizen capable of bearing arms becomes liable to military service on completing his twentieth year. Exemption by payment, or by providing a substitute, is not allowed; and those who are exempted on physical grounds are required to pay a sum of money, proportioned to their means, into the military pension fund. Temporary exemptions are, however, granted, as in other armies, to only sons of widows and others who are the sole supports of families. The period of service, or liability to service, lasts for twelve years. The annual contingent of young men passed as fit for service is divided, by lot into three classes. The first form the standing army, and serve for three years in the ranks, seven in the reserve of the army, and two in the landwehr. The strength of this first class is determined by the annual requirements of the army, and was fixed at 95,000. The second class forms the "Ersatz" reserve, or reserve for recruits of the standing army. They are not trained at all, but for ten years remain liable to be called in in case of war to fill the depôts and replace the casualties of the field army. The total strength of the "Ersatz" reserve may not exceed that of one year's contingent for the active army; the annual "Ersatz" reserve contingent is therefore fixed at $\frac{1}{10}$th of this. The third class, including all who are not drawn for the two preceding ones, are passed at once into the landwehr, in which they serve their twelve years. The organisation of the landwehr varies in the different provinces. Austria, as far as its military institutions are concerned, is divided into four distinct provinces, viz., Austria proper, Hungary, Tyrol and Vorarlberg, and the military frontier. The landwehr of these provinces are distinct, and cannot be moved out of their own provinces except by authority of the Reichsrath or central parliament. Most of the landwehr are trained for eight weeks on first joining, and fourteen days annually afterwards. The Hungarian militia, or "honveds," as they are called, are better trained than the others. Apparently with the object of providing a more distinctly national force, the Hungarian diet has made arrangements by which one company of each regiment is kept permanently embodied for instruction purposes, so that every man shall have a full year's training. The landwehr also includes the men who have completed their ten years in the army and reserve, and have to serve for two years in the landwehr. These are intended to provide a steadying element of old soldiers; but as many of them have only actually served two years in the ranks, and been away from their colours for eight, their value is doubtful. The number of young men coming of age and fit for service amounts to 140,000 to 150,000 annually. Of these, 95,000 are passed into the army, and about 10,000 into the "Ersatz" reserve; and the balance, averaging about 40,000, into the landwehr. The landwehr thus comprises two years' contingents of old soldiers (which, after deductions, may be estimated at about 150,000), and twelve years' contingents of about 40,000; or a total, after allowing for casualties, of between 500,000 and 600,000. The actual organisation, however, only provides for incorporating about one-third of this number. Service in the landsturm is voluntary, except in Tyrol, where all the male population capable of bearing arms are enrolled, and divided into two classes; the first including all between 18 and 39 who are not actually serving in the army or landwehr, the second those between 30 and 45. All liability ceases at the age of 45.

The standing army consists of—

	Peace Establishment.	War Establishment.
80 Regiments of Infantry,	149,720	485,440
40 Battalions of Rifles,	19,860	58,430
Total Infantry,	169,580	543,870
41 Regiments of Cavalry,	44,000	58,670
13 Regiments Field Artillery,	19,210	41,870
12 Battalions Garrison,	7,790	18,910
Total Artillery,	27,000	60,780
2 Regiments of Engineers,	5,710	16,350
1 Regiment of Pioneers,	2,800	7,750
12 Squadrons of Train,	2,600	30,900
Engineers and Train,	11,110	55,000
Miscellaneous Establishments,	23,860	33,760
Grand Total,	275,550	752,080

with 644 guns on peace establishment, and 1600 on war establishment. There is no special corps of guards, as in the Prussian and Russian armies; the "imperial and royal guards," which include the archers of the body-guard, the palace guard, the Hungarian crown guard, &c., only number 600 in all; and their duties are ceremonial and police rather than combatant.

Infantry.—An Austrian infantry regiment consists of 5 field battalions of 4 companies each, and 1 depôt battalion of 5 companies. In peace time the first three battalions are maintained on a peace-establishment of 386 of all ranks, the fourth and fifth on a reduced or *cadre* establishment of 300, and the depôt battalion in *cadre* only (21 officers and non-commissioned officers). The first three battalions are mobile, their stations being determined by the *ordre de bataille;* and they are always under the immediate command of the colonel of the regiment. The fourth and fifth and depôt battalions remain permanently at the headquarter station of the regimental recruiting district, and are under the command of a colonel or lieutenant-colonel (regimental second in command), called the reserve commander, who is also head of the recruiting district, and charged with all duties connected with the annual conscription, calling out of reserves, &c. The captain commanding the depôt battalion acts as his assistant in these duties. The staff of the depôt battalion conduct all business relating to the muster-rolls and registers of reserve and furlough men, and have custody of the augmentation stores of clothing, arms, ammunition, &c. Its own muster-roll is composed mainly of men who, after an eight weeks' training, have been sent on furlough, but held ready to fill vacancies occurring in the field battalions. The annual contingent of recruits is distributed among the five field battalions, and trained at their headquarters. In war time the five field battalions are raised to a war strength of 952 of all ranks, and the depôt battalion to 1155, by calling in the reserve and furlough men.

If the field force is still found insufficient, a sixth field battalion may be formed from the first four companies of the depôt battalion; and the fifth depôt company, under the command of the deputy of the district commander, then takes over all the depôt duties, being augmented for the purpose. The regiment forms two distinct bodies, the first three battalions, under the regimental commander, taking their place in the active army according to the *ordre de bataille;* the remaining two (or three) forming a "reserve regiment," bearing the same number, which may or may not be brigaded with its own regiment.

A *rifle battalion* consists of four field companies, a reserve company, and a depôt company: the four field companies forming a field battalion, which is stationed according to the *ordre de bataille,* while the reserve and depôt companies remain at the recruiting headquarters. In peace time the field battalion has a strength of 460 of all ranks, the reserve company 72, and the depôt company a *cadre* only. In war the field battalion is augmented to 989, the reserve company to 240, and the depôt company to 232. The 40 reserve companies are formed into 10 reserve battalions of 4 companies each; and, if necessary, 10 additional reserve battalions can be formed from the depôt companies, leaving only a sufficient staff to train the "Ersatz" reserve and perform the other depôt duties. Seven of the existing rifle battalions form together the "Imperial Tyrol Rifle Regiment;" the remainder are single battalions, numbered from 1 to 33.

The Austrian infantry stand two deep, but in somewhat looser order than is usual in other armies; their usual formation is in line of company columns, with intervals of three paces if in "mass," or deploying intervals if extended, the companies being formed in columns of sections. Their movements are rather loose but quick; and their new drill gives great independence of action to captains and subordinate commanders. They are armed with breech-loading rifles, partly on the "Wänzl" pattern, and partly on the "Werndl." The troops armed with the former carry 60 rounds, those armed with the latter 72 rounds of ammunition; and the regimental ammunition waggons carry in addition 30 rounds for the former and 36 for the latter. The old white tunic, long distinctive of the Austrian army, has been abolished, and replaced by a serviceable blue-grey uniform. The Hungarian regiments are distinguished by wearing pantaloons, fitting close to the leg and going inside the boot, instead of the trousers worn by the rest of the infantry.

Cavalry.—The cavalry consists of 14 regiments of dragoons, 16 of hussars, and 11 of lancers. The cuirassiers were converted into dragoons after the war of 1866 (only 2 dragoon regiments existed at the outbreak of that war), and the distinction between the heavy and light cavalry was abolished at the same time. The dragoon regiments are mostly raised in the German provinces of Austria, the hussars in Hungary, and the lancers in the Polish provinces.

A cavalry regiment consists of 6 field squadrons, a depôt, and a reserve squadron. The 6 field squadrons are kept permanently on a war footing, and form the field regiment which in peace time is stationed according to the *ordre de bataille,* and in war joins the active army: its establishment is 30 officers, 996 non-commissioned officers and men, and 900 horses. The reserve squadron does not exist in peace time, but is formed on mobilisation from the depôt, and has the same establishment as a field squadron (171 men and 150 horses); it is chiefly employed as "staff" cavalry,—to furnish orderlies, escort convoys, watch lines of communication, &c. The depôt squadron is maintained as a *cadre* only (19 of all ranks) in peace time, but in war time, besides forming the reserve squadron, is itself raised to a strength of a field squadron. The depôt *cadre* is permanently stationed in the recruiting district (a cavalry regiment recruits from one or more adjoining infantry recruiting districts), and has charge of the clothing, arms, and equipment of all kinds of the furlough and reserve men, and the registers and muster-rolls, but has nothing to do with the training of either recruits or young horses, who are sent direct to the field squadrons. In recruiting for the cavalry, young men of strong frame, accustomed to horses, and of a minimum height of 5 feet $3\frac{1}{2}$ inches, are selected. The remounts of horses are bought by commissions, and are trained and broken at the headquarters of the field squadrons; 12 per cent. of its establishment being the maximum number of remounts allowed yearly to a regiment. The Austrian cavalry has always borne a very high reputation, and its drill is considered by competent judges to be the best in Europe. Much of the old pedantry of drill has recently been swept away, and replaced by a more serviceable system. The soldiers now rise in their stirrups, ride with both hands, and only draw swords when necessary. The instruction of recruits and training of the horses falls almost entirely on the subaltern officers of the field squadrons—commencing on the 1st October, when the annual contingent of recruits is called in, and lasting till the end of June, when the tactical instruction of the squadron is supposed to be complete; from July to September is devoted to drilling in regiments and larger bodies. The hussars and dragoons are armed with breech-loading carbines and swords; of the lancers, 32 men per squadron carry carbines, the rest lances, pistol, and sword.

Artillery.—The artillery consists of 13 regiments of field artillery and 12 battalions of garrison artillery. A regiment of field artillery on peace establishment consists of 12 batteries, viz., four 4-pounder field batteries, three 4-pounder horse batteries, and five 8-pounder field batteries; and the *cadres* for two more 8-pounder batteries, a depôt battery, and five ammunition columns. The batteries have only 4 guns horsed in peace. The *cadres* of the depôt and two 8-pounder batteries remain at the headquarter station of the recruiting district; the other batteries are stationed and detached according to circumstances. In war the batteries are raised to a strength of 170 or 200 men, with 8 guns, 8 ammunition and 6 other waggons, and 109 to 147 horses. Two additional 8-pounder field batteries and a depôt battery are formed by each regiment from its *cadres*, and 5 (in some regiments 6) ammunition columns. A field artillery regiment on war establishment thus numbers 14 batteries or 112 guns; and as a rule a regiment is attached to each army corps of 3 infantry divisions Of the ammunition columns, 3 carry artillery and infantry ammunition in about equal proportions (12 infantry ammunition waggons and 14 artillery waggons), and are attached, one to each infantry division; the others carry principally artillery ammunition, and small-arm ammunition for the cavalry, &c., and are attached to the army corps headquarters or the army ammunition park. The Austrian field guns are rifled muzzle-loaders, of bronze. The 4-pounders and their ammunition waggons have four horses in the field batteries, and six in the horse batteries; the 8-pounders and their ammunition waggons are six-horsed. A 4-pounder battery carries 156 rounds per gun an 8-pounder 128 rounds. The remounts of horses are obtained by purchase as in the cavalry, but a larger and heavier class of horse is selected for the artillery.

A battalion of garrison artillery consists of 6 companies, of which in peace time 5 are maintained on a peace establishment of 113 of all ranks, and 1 on a *cadre* establishment. In war they are all augmented to a strength of 234. The companies of garrison artillery are employed in the defence or attack of fortresses. A small number of mountain batteries, armed with 3-pounder rifled bronze mountain guns, are attached to the garrison battalions.

The artillery further includes a certain number of "artillery reserve establishments" (siege parks, reserve ammunition parks, &c.), which are only organised in war, and the "artillery material department," which is charged with the construction and supply of all warlike stores in peace, and in war has further to furnish companies of field artificers to the siege parks and artillery reserve establishments. The great factory and depôt for all artillery *matériel* is the artillery arsenal at Vienna, an establishment of great antiquity and celebrity. The principal powder factory is at Stein, near Laibach. Laboratories are established at Wiener-Neustadt, at Vienna, in immediate connection with the arsenal, and at most of the principal artillery stations.

Engineers.—The engineers include two regiments of engineers and one of pioneers. A regiment of *engineers* consists of 5 field battalions of 4 companies, 8 reserve companies, and a depôt battalion. In peace time the reserve companies and depôt battalions are maintained in *cadre* only. In war time all the companies are raised to a strength of about 230 of all ranks; the field battalions accompany the active army, a company being usually attached to each infantry division, and a battalion to the army reserve; the reserve companies are employed on the lines of communication. The general duties of the engineers consist in carrying out all works connected with the investment, attack, and defence of fortresses, strengthening positions, opening communications, &c. The *pioneers* form 1 regiment of 5 battalions; each battalion composed of 4 field companies, 1 reserve company (in *cadre* only in peace time), and a *matériel* reserve. In time of war each battalion forms a depôt company as well. The pioneers are charged with the pontoon equipment; the construction of all bridges; and the construction, repair, and working or destruction of railways and telegraphs. They form 15 "field railway divisions" in war, 5 of which are kept mobilised in time of peace, to afford instruction in this most important branch of modern military engineering. The officers of the pioneer corps are trained at the cadet school at Hainburg. Special care is taken in the selection of recruits for the engineer and pioneer regiments. As a rule, they must be of a minimum height of 5 feet 6 inches, of considerable physical strength, and of some education; and most of them must be mechanics. The standard of height is, however, relaxed in the case of skilled workmen.

Military Train.—The transport of the Austrian army is provided for partly by the military train, partly by the regimental transport attached to the several arms. The military train consists of 36 field squadrons, 36 reserve squadrons (in *cadre* only in peace time), 6 depôt squadrons, and 6 *matériel* depôts. In peace time the train forms a mere nucleus, capable of expansion in war, and supplies the transport required by the military authorities in some of the chief garrison towns; its whole strength is only 2500 men, with 500 waggons and 1250 horses. In war time it is raised to a total of nearly 31,000 men, with 12,000 waggons and 36,000 horses. The 36 field squadrons are raised to a strength which varies from 173 men and 197 horses, to 547 men and 718 horses, according to the special duties they have to perform. The 36 reserve squadrons are raised to the same strength, and a similar number of "Ersatz" divisions are formed to carry out the duties which in peace time were performed by the field squadrons. On mobilisation the field squadrons, as a rule, transfer the horses actually in their possession to the field artillery; and are themselves completed in horses partly by purchase and partly by requisition, and in men from the reserve, who have been trained in their ranks, and from the cavalry reserve men who are not required to complete the cavalry regiments. When an army takes the field, one squadron of military train is allotted to each infantry or cavalry division, one to each army and army corps headquarters, one to each pioneer battalion for the transport of its bridge equipment, and one to the artillery reserve and ammunition park. A squadron attached to an infantry or cavalry division is formed into five sections, of which the first provides the necessary transport for the divisional and brigade staffs and the field hospital; the second, third, and fourth for the provision column; while the fifth or reserve section supplies all necessary reliefs and minor miscellaneous requirements. Regimental transport is provided for by the regimental train, each infantry regiment having permanently attached to it 8 baggage waggons, 6 commissariat store waggons, and 3 ammunition waggons; and each cavalry regiment, 4 baggage and 13 supply waggons.

General Organisation and Administration of the Army.—Since 1867 the Austrian empire has consisted of two distinct states, a German or Cis-Leithan empire, commonly known as Austria proper, and a Magyar, or Trans-Leithan, kingdom, known as Hungary. Each of these countries has its own parliament, ministers, and government. The connecting ties between them are a common hereditary sovereign, a governing body known as the Delegations, and a common army and navy. The war strength of 800,000, at which the naval and military forces of the empire are fixed, is distributed between Austria and Hungary in proportion to their populations; Austria contributing 470,368, and Hungary 329,632. The annual contingents are divided in similar proportions. The cost of the maintenance of the army, which in 1871 was estimated at £10,500,000, is charged in the budget for the "common affairs of the empire," laid before the Delegations. A portion of this is met by the proceeds of the customs, and other sources of revenue set apart to meet the common expenditure; the rest is defrayed by the two states in the proportion of $\frac{7}{10}$ths from Austria, and $\frac{3}{10}$ths from Hungary. The emperor is commander-in-chief of the army; the military and administrative business is centred in the War Department, which is presided over by the War Minister and his deputy. The empire is divided into 16 military territorial districts. Of these, 7 are called "general commands," and have general officers of high rank specially appointed to them; the remainder are termed "military commands," and are commanded by the senior divisional commander stationed in the district. Each commander of a district is assisted by a general officer of lower rank, who has special duties to perform, and takes the place of the commander in the event of the latter being called away on mobilisation. The military districts again are subdivided into 80 regimental recruiting districts, corresponding to the 80 infantry regiments, each under the superintendence of the reserve commander or second colonel of the regiment, whose duties correspond closely to the landwehr battalion commanders in the Prussian organisation.

The Austrians have no permanent corps organisation; their standing army is formed into independent divisions, which have no fixed stations, but are distributed about the empire according to circumstances, and occasionally relieve one another. There are 32 such divisions, of 2 infantry brigades each, 18 of these have cavalry brigades attached to them. In war time 3 infantry divisions, with a regiment of artillery and proportion of cavalry, would usually be united to form an army corps; but the division remains the principal unit of organisation. The following gives the strength and details of an Austrian infantry division in the field:—

	Officers and Men.	Horses.	Guns.	Waggons.
Divisional Staff,	379	114	...	14
2 Brigades Infantry (4 regiments = 12 battalions, ...	11,882	280	...	74
2 Battalions Rifles,	1,978	8	...	8
Cavalry (3 squadrons),	531	476	...	8
Artillery (3 batteries),	552	370	24	43
1 Company Engineers,	234	15	...	6
Ammunition column,	170	166	...	32
Field Hospital,	133	54	...	21
Provision column,	242	288	...	158
Total,	16,101	1771	24	364

This includes all, non-combatants as well as combatants, or the "rationing strength" as it is termed. The combatant strength of a division is 12,884 infantry, 472 cavalry, and 24 guns.

The Austrian army, though long the most perfectly equipped in Europe, and always distinguished for its appearance, its discipline, the strong *esprit de corps* of its officers, and the scientific training of its staff, has yet the most unfortunate history of all the great European armies. Defeated repeatedly by Frederick in the Seven Years' War, by Napoleon in the Revolutionary wars, and later by the French in 1859 and the Prussians in 1866, the Italians are the only nation over whom it can claim to have been generally victorious. Yet its spirit has always remained unbroken; and however severe the defeat, however disastrous the campaign, no reverse ever brought Austria to the condition of Prussia after Jena, or of France after Sedan. There are several causes to which this almost uniform ill-success may be attributed. Trusting to diplomacy rather than force of arms, her strategy has always been cautious and vacillating. The hands of her generals have repeatedly been held when in the act of striking. But the same caution which often prevented her reaping the successes actually within her reach, or retrieving disasters which were not yet irremediable, also left her always with a reserve and a show of power still formidable. Austria has also suffered from the heterogeneous composition of her army. Germans, Hungarians, Czechs, Poles, Croats, Italians, served together under officers who frequently could not communicate with their men. The Germans, or Austrians proper, are loyal and faithful to the house of Hapsburg; but the other nationalities were not only indifferent, but frequently hostile, and instances of whole regiments surrendering to the enemy rather than fight for a cause they detested, are common in the history of her wars. The only ties by which this heterogeneous mass was bound together, was a strict and somewhat harsh discipline, and the strong loyalty and *esprit de corps* of its body of officers. The Austrian officers have always been distinguished by a *cameraderie* peculiar to themselves. Officers of various nations and of very different social standing meet on terms of perfect equality, and intimacy as the "emperor's servants," and no distinctions are acknowledged within the army save those of military rank. The general physique and intelligence of the rank and file of the army is rather below than above the average. Some of the Hungarian regiments are fine bodies of men, but the standard in other parts of the empire is very low, and education has made but little progress in the outlying provinces. The men are generally docile and somewhat phlegmatic, but have neither the *élan* of the French nor the stubbornness of the northern nations.

Since 1866 a great change has taken place in the character of the Austrian forces. The disastrous campaigns of 1859 and 1866 shook the confidence of the nation in that fine imperial army that ever showed so gallantly on parade, and yet seemed ever to suffer defeat in the field.

The army was reorganised on something of the Prussian model, universal personal service introducing a more intelligent and more highly educated element into the ranks. The cession of her last possessions in Italy, and the independent constitution granted to Hungary, removed the principal causes of disaffection. Her regimental officers, who formerly, though gallant and loyal gentlemen, were not distinguished for study of their profession, are now subjected to tests more severe than in any other country; while the constant renewal of the rank and file, and even of the non-commissioned officers, under the three years' system, throws on them almost the whole of the arduous and ever-recurring labour of training the annual contingents of recruits. Her rigid drill has given place to one of exceptional freedom. Even the outward appearance of the army is changed; and the gay uniforms for which Austria was once celebrated have given place to more sober and serviceable ones. Whatever may be the result of the next struggle she finds herself engaged in, none who have watched her military development will deny that she deserves success, so far as success can be earned by a frank acceptance of the lessons taught in her disasters, by honest and persevering efforts to remedy the defects laid bare, and by the loyal devotion with which the officers and the country have accepted the new and arduous duties thrown on them.

Russian Army.

Of all European powers, Russia maintains by far the largest army. In 1870 its peace establishment amounted to three-quarters of a million, and its war establishment to a million and a quarter; and when the changes which were commenced in that year have taken full effect, her available war strength will be increased to nearly two millions. But even this enormous force is not excessive when measured by the vast extent of her possessions (7,500,000 square miles), or her population (82 millions); it is calculated that a levy of 25 per cent. of the young men coming annually of age will suffice for the requirements of the army, and that military service will thus fall more lightly in Russia than in any other great nation of the Continent.

Before the recent changes the Russian army was a reflex of the social condition of the country. As in civil life there was practically no middle class, so in the army there was a wide gulf between the officer and the soldier. The officers were mainly drawn from the nobility, every young man of rank being practically compelled to serve; the soldiers were entirely drawn from the serfs. Although every one was nominally liable to serve, numerous exemptions were made in favour of merchants, skilled mechanics, and others whose services were accounted more valuable to the nation in their civil capacities, and the purchase of substitutes was allowed; so that actually the recruits were drawn almost entirely from the lowest class of agricultural labourers. Service was nominally for life, though after a certain number of years the soldier was allowed his discharge on pension. The army was recruited by an annual levy of so many per thousand of the male population (usually from 4 to 6); the number of men required from each village or district being notified, and the headmen and elders charged with furnishing them. The power thus placed in the hands of the small local authorities was most despotically used, and a youth who had incurred the displeasure of his superiors was surely drafted off to the army. Although the army carried with it the advantages of ultimate freedom and a pension, the time in the ranks was so long, its hardships so great, and the pay so miserably small, that the service was very unpopular, and severe measures were necessary to prevent the recruits deserting on their way to the depôts. Subsequent to the Crimean war, however, various steps were taken to improve the condition of the soldier; the term of service in the ranks, first fixed at twenty years, was reduced to fifteen, and a system of unlimited furloughs introduced, under which the soldier was sent to his home after seven or eight years' service, though liable to recall if needed. The liberation of the serfs in 1861 paved the way for still further reforms, and by an imperial ukase of the 4th (16th) November 1870, the principle of universal personal liability to service was established. By the new army organisation law, every Russian is liable to service on attaining his twenty-first year. The purchase of exemption or of substitutes is prohibited; but it seems doubtful whether this clause will be fully enforced, and hitherto the purchase of exemption at a fixed rate of 800 roubles (about £120) has been permitted. The conscription takes place annually between the 1st November and 15th December, when the number required to complete the active army (estimated at about 25 per cent. of those liable to service) are chosen by lot. The period of service is fifteen years,—of which four are spent in the ranks; two years on furlough, liable to recall at any moment; and nine years in the reserves, which can only be called out in case of war or national danger. In the cavalry and horse artillery, the time with the colours is extended to five years, and that in the reserve is shortened. Those who are not drawn for the active army are put through a short course of training, and then sent to their homes; but for six years they remain liable to be called in to replace casualties in the active army in case of war. After this they pass into the national legions, which include all able-bodied men between the ages of 20 and 38 not actually serving in the army or navy. As in Prussia, certain advantages are given to young men of means and good education, who are allowed to shorten their period of service in the ranks. Special regulations apply to the Ukraine and provinces which furnish the Cossacks and other irregular troops.

The military resources of Russia thus consist of the *active army*, or men serving with the colours; the *reserves*, who have completed their period in the ranks, but rejoin the army in case of war; the *irregular troops*, or Cossacks; and the *national legions*, or armed levies, only called out in exceptional cases, such as invasion. The regular army is formed by the active army, completed in time of war from the reserves, and is divided into *field troops* and *local troops*,—the former furnishing the armies for the field, the latter the garrisons, and the depôts at which the recruits are assembled and trained, and whence the field troops are fed. The local troops, as their name implies, are permanently localised; the field troops are not, as in Prussia, connected with certain districts, but draw their recruits indiscriminately from the whole empire, and are moved from one part to another as occasion demands.

The field troops of the regular army consist of 612 battalions of infantry, 236 squadrons of cavalry, 16 battalions of sappers and engineers, and 306 batteries of guns and mitrailleuses. They are divided into guards and line, each having its due proportion of all arms, and are organised in detail as follows:—

Infantry.—The infantry consists of—

12	Regiments of Guards (including 2 Grenadiers) of 3 battalions each.	
12	,,	Grenadiers of 3 battalions each.
4	,,	Caucasus Grenadiers of 4 battalions each.
148	,,	the Line of 3 battalions each.
12	,,	Infantry of the Caucasus of 4 battalions each.
4	Battalions of Rifles of the Guard.	
20	,, ,,	Line.
8	,, ,,	Caucasus and Turkestan.

A battalion of the guards or line consists of 4 line companies and 1 of rifles; it has four different establishments, viz., "*cadre*" strength of 320 rank and file, "peace" strength of 500, "increased peace" strength of 680, and "war" strength of 900 rank and file. This is exclusive of musicians, officers' servants, &c. A regiment on war establishment numbers 81 officers, 270 non-commissioned officers, 2700 rank and file, 96 drummers and buglers, and 259 artificers, officers' servants, and other non-combatants; and is accompanied by 12 officers' horses, 173 draught horses, and 41 ammunition, ambulance, and baggage waggons. Rifle battalions consist of 4 companies only, and have three establishments,—"war," of 720 rank and file; "increased peace," of 544; and "peace," of 400 rank and file.

The Russian infantry is formed in two ranks. On parade the four line companies of a battalion stand in order from right to left, while the rifle company stands at fifty paces in rear of the centre; but for manœuvring purposes the three rifle companies of the regiment are often united to form a separate battalion. The guards still maintain on parade much of the stiffness and precision for which the Russian army was once famous; but generally the movements of the infantry are loose and rapid. In the main their drill resembles that of the German army; the commonest formation for march and manœuvring is the company column of sections. The men are armed with the "Berdan" breech-loading rifle, a bayonet (which is always carried fixed), and a short two-edged sword. They carry 60 rounds of ammunition in two pouches, and 40 rounds are carried in the regimental ammunition carts, so that there is always present with the regiment 100 rounds per man; and the divisional reserves carry 60 rounds per man besides. A certain number of entrenching tools are issued to each company, and on service are carried by the men in turns. The *clothing* is of somewhat coarse texture, but very serviceable; that of the guards is of slightly finer material than is supplied to the rest of the army. All infantry alike wear tunic and trousers of dark green cloth (or white linen trousers in summer time), long boots into which the trousers are tucked in the field or for marching, cap or "kepi" of black cloth with straight peak, metal badge, and horse-hair plume, and cloak of reddish-grey cloth with a dark-coloured hood. The tunics of the guard are turned back in front, and faced with red or yellow. Regiments are distinguished by the colour of the "paroli" (a strip of cloth worn on the collar) and of the shoulder straps. The belts of the first three regiments of the guard and grenadier divisions (with the exception of the rifle companies) are white; those of all others black. The knapsack is rather large, and made of black calf-skin. A white smock frock, intended as a fatigue dress, is worn in summer at drill.

A Russian regiment is very completely equipped with transport. Every company has two waggons attached to it, one carrying ammunition (40 rounds per man), the other six days' rations of biscuit, salt, and other provisions and stores. In addition to these the regiment has an orderly-room waggon, a paymaster's waggon, a store and implement waggon, four ambulance waggons, and two hospital and medicine carts. All these are kept in store in peace time with the headquarters of the regiment; but only one waggon per company is horsed. In war time most of the waggons are four-horsed; but some still have shafts, and are drawn by three horses abreast.

The regimental staff comprises 1 colonel, 3 lieutenant-colonels, 1 supernumerary field officer, a regimental adjutant, paymaster, quartermaster, and instructor in arms, 3 battalion adjutants, a chaplain, and 4 surgeons. In the field each company is attended by an apothecary, provided with the necessary appliances; and the officers' servants and other unarmed men are taught the elementary principles of military surgery, and trained to the duties of stretcher-bearers.

Cavalry.—The regular cavalry consists of 10 regiments of the guard, 18 regiments of dragoons, 14 regiments of lancers, and 14 regiments of hussars.

The cavalry of the guard comprise 4 regiments of cuirassiers, 2 of lancers, 2 of hussars, 1 of dragoons, and 1 of horse grenadiers. There are also 2 regiments of Cossacks of the guard, who in peace time furnish 2 squadrons each for duty, and in war take the field with 6 squadrons, and may fairly be included among the regular troops.

All regiments of cavalry are organised in the same manner, and consist of 4 field squadrons and 1 reserve squadron, the latter belonging to the "local troops." They have two establishments, viz., "war," of 128 men per squadron (mounted); and "peace," of 112 men per squadron. The war establishment of a cavalry regiment is 32 officers, 73 non-commissioned officers, 512 rank and file, 16 trumpeters, and 305 non-combatants, including dismounted men in reserve, officers' servants, artificers, &c.; or a total of 938 officers and men, with 693 horses and 11 carriages. The formation and manœuvres of the Russian cavalry do not differ materially from those of other armies of Europe, except in the case of dragoons, who are armed with a rifle and bayonet, and specially trained to act as infantry. In all other cavalry the front rank is armed with a lance in addition to sword and revolver. The rear rank is armed with sword and carbine in lancer and hussar regiments, and sword and revolver in cuirassier regiments. The cuirassiers wear white tunics with shoulder scales, cuirass, and helmet; the dragoons a dark green tunic, with scales and cloth cap; the lancers, a blue tunic with metal epaulettes, and the czapka, or lancer cap; and the hussars, a blue tunic and cloth cap. Only the hussars of the guard wear bearskin caps and pelisses. The guards have parade trousers of black or dark blue with stripes; but in the field, trousers or pantaloons of a greyish blue cloth are worn by all cavalry alike. The saddlery is simple in construction, though somewhat heavy and cumbrous. Four separate folds of felt, each $\frac{1}{4}$ inch thick, support a wooden frame previously fitted to the horse's bare back; on the wooden frame is strapped the horse rug, and the saddle is complete. When one fold of felt is wet or hardened by dried perspiration, it is replaced by another, and sore backs are almost unknown. The men as a rule ride fairly well, though not so well as the Austrian or English cavalry; and the peculiar seat, and height of the saddle above the horse's back, strike the eye as ungainly. The horses, though often small, are hardy and enduring; they are provided partly from the Government breeding establishments and partly by purchase, and come mostly from the south-eastern provinces of the empire. They are not taken on the strength of the regiment until rising six years old, and are cast on completing their twelfth year, this securing that they shall always be in their prime, and fit for the severe work of active service.

The staff of a cavalry regiment consists of a lieutenant-colonel commanding, two field-officers commanding divisions (of two squadrons each), and regimental adjutant, paymaster, quartermaster, and instructor in arms. Each regiment has also a chaplain, two surgeons, and a veterinary surgeon. Each squadron has its provision waggon, and each regiment has an ambulance waggon, and three store and office waggons. Dragoon regiments have two ammunition waggons carrying 30 rounds per man; other regiments have only one.

Artillery.—The field artillery consists of 3 brigades of field and 1 of horse artillery of the guard; 44 brigades of field and 7 of horse artillery of the line; and 3 Turkestan brigades.

A brigade of field artillery consists of six batteries, viz., three heavy, two light, and one of mitrailleuses. The horse artillery brigade of the guard comprises five light batteries (including one of the Don Cossacks of the guard); the remaining horse brigades have only two batteries each. The Turkestan brigades vary slightly in composition. The Russian artillery thus numbers—143 heavy field batteries; 100 light field batteries; 19 batteries of horse artillery; 4 mountain batteries; and 50 batteries of mitrailleuses; or a total of 2128 guns and 400 mitrailleuses.

A battery has three establishments—"peace," with only 4 guns and 2 waggons horsed; "increased peace," with 8 guns and 8 waggons; and "war," with 8 guns and 16 (or 24) waggons. On war establishment a heavy field battery numbers 6 officers, 316 non-commissioned officers and men (including artificers, &c.), and 214 horses; with 8 guns, 24 ammunition waggons, and 9 provision and store carriages. A light battery has 261 officers and men, 160 horses, 8 guns, 16 ammunition and 8 other waggons and carriages. The guns are of bronze or cast steel, breech-loading and rifled on the Prussian system. The mitrailleuse batteries are armed with a 10-barrelled gun on the Gatling system, slightly modified by the Russian general Gorloff. A heavy battery carries 120 rounds per gun, a light battery 130, and a mitrailleuse battery a total of 6290 rounds. The harness is rough and clumsy with long rope traces. The dress of the men of the field batteries is similar to that of the infantry, and that of the horse artillery to that of the dragoons.

Engineers.—The corps is divided into sappers and pontoniers. The sappers form 11 field battalions, 1 field company (Turkestan), and four reserve battalions (local troops); also 2 engineer field parks, 2 siege parks, and 6 field telegraph parks. The pontoniers form 6 half-battalions. A field battalion of sappers consists of 4 companies, and has a war establishment of 900 rank and file, and a peace establishment of 600. The half-battalions of pontoniers consist of two companies, and have a war establishment of 13 officers, 469 non-commissioned officers and men, with 392 horses, 52 pontoon and 10 other waggons and carriages; and carry 26 iron pontoons and 12 trestles, sufficient to form 700 feet of bridge.

Organisation of the Field Army.—The organisation of the Russian army is entirely divisional; two or more divisions may be brought together to form an army corps, but no such organisation exists permanently. The infantry is formed in 47 divisions, viz., 3 of guards, 3 of grenadiers, 1 of Caucasus grenadiers, and 40 of the line. Each division consists of 4 regiments or 12 battalions (with the exception of the divisions of the Caucasus, which have 16 battalions), and has attached to it a brigade of field artillery, but no cavalry or rifles. The rifles are organised in separate brigades of 4 battalions each, and form 8 brigades (1 guard, 1 of the Caucasus, 1 of Turkestan, and 5 of the line); and the cavalry in cavalry divisions of six regiments, to each of which is attached a brigade of horse artillery. With the exception of the guards (of whom two divisions are always stationed in St Petersburg) and some of the troops of the Caucasus and Turkestan, these divisions have no permanent stations, but relieve one another from time to time. Five infantry and two cavalry divisions are usually stationed in the St Petersburg district; 15 infantry and 2 cavalry divisions in the Warsaw and Vilna districts (Poland and Polish frontier) 8 infantry and 2 cavalry in Kiev and Odessa (south-eastern provinces); 7 infantry and 1 cavalry in Moscow; and 6 infantry and 1 cavalry in the Caucasus. Of the cavalry, the guard divisions and three line divisions are usually maintained on war footing, the remainder on the peace establishment; the artillery all on peace establishment. Of the infantry, a few battalions in Turkestan are alone maintained on war footing; the divisions in the Caucasus are mostly on the "increased peace" establishment; the guards and grenadier divisions, and those occupying Warsaw and the great fortresses, on "peace" footing; and those distributed about the interior on *cadre* establishment.

The following was the peace and war strength of the field army in 1873:—

	Peace.	War.
Infantry (612 battalions),	364,422	694,511
Cavalry (236 squadrons),	38,306	49,183
Artillery,	41,731	48,773
Engineers,	13,413	16,203
Total,	457,872	808,670

Local Troops.—That portion of the Russian army which is stationary in peace is distinguished by the name of "local troops;" and these again are divided into "reserve and depôt troops" and "troops for service in the interior." The reorganisation of these forces was commenced in 1873, but will take some years to complete.

According to the new organisation, the reserve and depôt troops will consist of 120 local battalions of infantry, each forming on mobilisation a three-battalion reserve regiment and a depôt battalion; 56 reserve squadrons of cavalry; 24 local batteries of artillery, forming in war 24 reserve artillery brigades (96 batteries) and 24 depôt batteries; and 5 reserve companies of sappers. In peace time they are little more than *cadres*, distributed according to population, and are charged with the training of recruits and reserve and furlough men. In war they form a reserve army of 30 infantry divisions and 24 artillery brigades, or about 420,000 men and 768 guns, available to reinforce the field army; and depôts numbering about 85,000 men.

The "troops for duty in the interior" consist—First, of 48 "frontier battalions," of which 24 are stationed in the Caucasus, 12 in Turkestan, and the remainder in the military districts of Orenburg and Eastern and Western Siberia. They are organised in all respects like the rest of the infantry, and have a war establishment of 1074, and a peace establishment of 615 of all ranks. Secondly, of "garrison infantry and artillery," intended for the defence of fortresses, and numbering 98 battalions and 59 (in war time 91) artillery companies. Thirdly, of "government battalions" and "local detachments," who do garrison duty in the capitals and towns, and act as police, guards, &c.; of these there are 70 battalions and 400 separate detachments, distributed throughout the empire, maintained on a reduced establishment in peace, but raised to a total war strength of 120,000 men when the field army is mobilised. Lastly, of "etappen detachments," stationed on the military roads, and charged with furnishing escorts to recruits and prisoners, and providing them with lodging and subsistence; and local artillery detachments, charged with the care of artillery material stored in large towns.

The total strength of the "local troops," when the new organisation has been completed, will amount to about 784,000 men and 816 guns.

Irregular Troops.—The irregular troops or Cossacks have always borne a most important share in the wars of Russia. In 1812 more than 100,000 were raised, and the services they rendered in that and the following campaigns made their name famous and a terror throughout Europe. In 1856 they raised 184,000 men, of whom about three-fourths were cavalry; but the Crimean war did not give the opportunity of utilising this class of troops.

The Cossacks have always been a race of free men; neither serfage nor any dependence upon the land has existed among them. It has been the policy of the Russian Government to foster their martial spirit, and various privileges have been granted to them with this object. They pay no taxes; but in lieu of this render military service, from the age of 19 to 40. Only a portion of this time is actually spent in the ranks; but in war time, by order of the emperor, the whole male population between the ages of 15 and 60 may be called to arms. The Cossacks are organised in "polks" or regiments of light cavalry, about 900 strong, and formed usually of six "sotnias" or squadrons; in battalions of infantry, about 1100 strong; and horse artillery batteries of 8 guns. In peace time a few squadrons are stationed at St Petersburg and Warsaw, furnishing escorts to the emperor and viceroy. The rest are distributed about the Cossack provinces and on the frontiers, maintaining the lines of communication in the wild Asiatic provinces. The force under arms in 1871 amounted to 66,000, forming 323 sotnias or squadrons, 35 companies of infantry, and 12 batteries. In war time this can be raised to—

Cavalry, 155 "polks" or regiments,	142,000
Infantry, 37 battalions,	41,000
Horse Artillery, 27 batteries,	6,000
	189,000

with 232 guns. In war time the divisional cavalry of the regular army is furnished by the Cossacks, one polk being attached to each infantry division for purposes of outpost duty, escorts, and orderlies.

Militia.—The militia or national legions include all men within the ages liable to service who have not served actively in the army. There is as yet no regular organisation for the militia, nor have the men been drilled; notwithstanding this, on the three occasions on which they have been called out (viz., 1807, 1812, and 1855), they have always been rapidly formed, and have done good service to the country. In 1855 the number actually raised was 366,000. The number liable to service in 1871 was over 500,000; and as the new law comes fully into action that number will be enormously increased.

Organisation and Administration.—The emperor is the Commander-in-Chief of the army, and exercises his authority through the War Minister. The War Ministry is divided into twelve sections or departments, including the imperial headquarters or military cabinet of the emperor; the council of war, which is the highest legislative and administrative authority in the empire; the headquarter staff; and the artillery, engineer, intendance, medical, &c., departments. For purposes of military administration the empire is divided into 14 military districts, corresponding to the civil "general governments," and 51 governments or military sub-districts. At the head of each military district is a general, who is also viceroy or governor-general, and has the supreme control of all affairs, civil as well as military. The local forces belonging to each military district are commanded by a local divisional commander, and the forces of each government by a local brigadier. In addition to the command of the local troops, these officers are charged with the keeping of the muster-rolls of men on furlough, &c., and generally with the arrangements for mobilisation. The field troops stationed in the district are under the command of their own divisional generals, subordinate to the district general. The guards and some of the regiments stationed in the fortresses and great towns are lodged in fairly comfortable barracks; but the accommodation generally is quite insufficient. The erection of barracks for the whole army is projected, and the necessary buildings have been commenced in many places; but it must be long before the plan can be fully carried out. Meanwhile a large part of the troops are billeted in the towns, and in some country districts are distributed among the villages, living with the peasants, and for months without seeing their officers or any opportunities for drill. During the summer months, May to October, the regiments and divisions are brought together in large standing camps for training, commencing with battalion and regimental drill, rifle practice, instruction in field fortification, &c., and concluding with brigade and divisional field-days and great manœuvres. In 1873, 445 infantry battalions, 238 squadrons, 93 sotnias of Cossacks, and 828 guns were thus assembled at the various camps of instruction, the largest of which were at Warsaw, where nearly 50,000 men were collected; and at Krasnoe Selo, near St Petersburg, where about 30,000 men, principally of the guard, were encamped.

The Russian guards, selected as they are with care from the vast military population of the empire, are perhaps the finest body of men in Europe; and with their brilliant and various uniforms, relieved by the Oriental picturesqueness of the Cossack squadrons, certainly present the most gorgeous and imposing military display to be seen anywhere. They have many special privileges, and all officers of the guards rank two grades higher than the corresponding ones of the line. The ordinary line soldier is rather below the average of European armies both in physique and intelligence; but he is generally a good marcher, capable of enduring great hardship and fatigue, and is good-natured, cheerful, obedient by instinct and habit, and imbued with a certain religious and superstitious loyalty, which is always a powerful motor, and at times can be excited to fanaticism. Of all their commanders, Suwaroff knew best how to appeal to this semi-barbarous and superstitious instinct, and to this he owed much of his extraordinary influence and brilliant successes. Generally, however, the Russian's strength lies rather in endurance than action; no army, the British perhaps excepted, fights so stubbornly and will endure such heavy losses without flinching. Hence the most bloody battles in modern history have been those fought against Russian troops,—Zorndorf and Kunnersdorf in Frederick's wars, Eylau and Borodino in Napoleon's time. Outwardly the discipline is good, though the intercourse between men and officers retains somewhat of that mixture of familiarity and servileness characteristic of a stage not far removed from slavery; but it may be questioned whether it is of the kind that will withstand the strain of war, or gives the officers that moral influence which alone tells in moments of danger or discouragement. The non-existence of a class corresponding to the lesser nobility of Germany or the gentry of England has always made the officering of the Russian army a matter of peculiar difficulty. The staff and scientific corps are largely officered by foreigners, mostly Germans; in the infantry the want is supplied to a certain extent by promotion from the ranks. The Russian army, like the nation, is in a transitional state. The liberation of the serfs was a vast constitutional change which could not make itself fully felt in less than a generation, and which affects the army as well as the nation. The introduction of personal service, applied to all classes, must materially alter its character. The Russian Government, fully alive to the present defects of the army, and also to its importance as a means of raising, educating, and disciplining the nation, is using every endeavour to instruct and improve the soldier. Regimental schools have been established throughout the army, at which the soldier is taught, either by or under the immediate supervision of his officers, for many hours a day during the long winter months. Higher class schools are also formed for the instruction of non-commissioned officers, where they receive not only a military education, embracing tactics, military history, field fortification, &c., but also a general education which qualifies them, on leaving the army, to become, as many do, teachers in the national schools, or to fill civil appointments. The physical training of the soldier is also attended to; gymnastics of all kinds are constantly plantised, and with such effect that the Russian soldier contrasts very markedly with the awkward, ungainly peasant.

The military power of Russia has been vastly increased of late years by the construction of the great strategic lines of railway which now traverse the empire in all directions, and enable her to concentrate her vast resources with ease and quickness. The immense extent of the empire has hitherto been an insuperable obstacle to the full development of her power. In 1854-56 the efforts made to hold the Crimea exhausted Russia more completely than a series of defeats in the heart of the empire could have done. For every man who actually reached the Crimea four were expended on the road from sickness and fatigue, and the total losses suffered in this war were estimated at the enormous amount of 450,000 men. Now reinforcements can be brought with ease by rail from the most distant provinces, and for a concentration on her south-western frontiers she has four distinct main lines of railway, connected by branch ones with every important military station. It is not to be wondered at that Prussia and Austria watch with uneasiness the development of the military resources of their powerful neighbour.

Italian Army.

The old Piedmontese law of conscription is the basis of the present military organisation of Italy, as its constitution is of the constitution of the new kingdom. The Piedmontese have long borne a high reputation among southern nations for their military qualities. The dukes of Savoy have played a not unimportant part in history, and showed special ability in preserving the independence of their small kingdom between two such powerful neighbours as France and Austria. During the wars of the French-Revolution Piedmont was temporarily absorbed into the French republic; but the kingdom of Sardinia was restored in 1815. Various causes combined to place Piedmont at the head of the national and liberal movement which agitated Italy during the ensuing thirty years, and bring her in direct antagonism to Austria. Charles Albert, her then ruler, had paid great attention to the army, and when Italy rose against Austria in 1848 he took the field with an excellent force of nearly 70,000 men. At the outset fortune favoured the arms of Italy; but the genius and energy of Radetsky, the veteran Austrian commander, soon turned the tide, and in the summer of 1849 the Piedmontese army was decisively defeated at Novarra, and her king compelled to sue for peace. Charles Albert abdicated in favour of his son Victor Emanuel, a prince who had already distinguished himself by his personal gallantry in the field. Under his care the army soon recovered its efficiency, and the force which joined the allied armies in the Crimea attracted general admiration from the excellence of its organisation, equipment, and discipline. In 1859 Piedmont again took up arms against Austria for the liberation of Italy; but this time she had the powerful assistance of France, and played but a subordinate part herself. In this campaign the Sardinian army was composed of one cavalry and five infantry divisions, and numbered about 60,000 combatants. By the peace of Villa Franca, Italy, with the exception of Venetia, was freed from the Austrians, and Lombardy was added to Piedmont. The revolutionary campaign of Garibaldi in the following year united the whole peninsula under the rule of Victor Emanuel, and in 1866, when Italy for the third time took up arms against Austria—this time as the ally of Prussia—her forces had risen to nearly 450,000, of whom about 270,000 actually took the field. But in quality these were far from being equal to the old Piedmontese army; and the northern army, under the personal command of the king, was defeated at Custozza by a much smaller force under the Archduke Albrecht of Austria. Since 1866 the army has been somewhat reduced, but increased care given to its organisation and training, and in manœuvring power it now stands high among the armies of Europe.

The existing organisation of the Italian army is determined by the laws of 1873. Every Italian is liable to personal service from the age of 18 to 40. Substitution (except in the case of brothers) and exemption by payment are abolished. Absolute exemption is only allowed to such as are physically unfit for service. Partial exemptions are allowed to only sons of widows, supports of families, &c., who are passed at once into the local militia without serving in the army. Temporary exemptions or "adjournments" may be granted for three successive years on urgent personal or family reasons. The remainder of the annual contingent is divided by lot into two classes. The first class serve eight years in the army, four in the active militia, and the rest of their time in the local militia. Of the eight years in the army, three in the infantry and five in the cavalry are usually spent with the colours; the remainder on furlough. Further, the Minister of War has the power to send home on furlough, after a year's service only, young men of exceptional character or intelligence, school teachers, artists, &c. The second class are liable to service in the several forces for the same periods, but are considered as on unlimited furlough, and only subjected to six months' training. One-year volunteers are received on the same conditions as in other armies. The numbers of the first class contingent are determined annually by law, and are distributed among the districts and cantons according to the number of men found fit for service. This is estimated at from 90,000 to 95,000; and the contingent of the first class was fixed in 1872 and 1873 at 65,000. The war strength of the army, exclusive of local or "sedentary" militia, is estimated at 750,000, of whom 375,000 are in the active army, or first line; 250,000 in the active militia, or second line; and 125,000 in the depôts. The peace establishment is fixed at 200,000.

The Italian army consists of 80 regiments of the line, 10 of *bersaglieri* (riflemen), 20 regiments of cavalry, 10 of artillery, and 2 of engineers. A regiment of the line consists of 3 battalions of 4 companies each, and numbers about 1500 men on peace and 3000 men on war footing. Eight of the existing regiments are grenadiers. The *bersaglieri* are formed in regiments of four battalions each, and are picked troops, armed with a shorter rifle, and especially trained to traverse long distances at a run. They are frequently used in conjunction with cavalry, and it is proposed to relieve them of their knapsacks, to increase their mobility still further. The cavalry consists of 5 regiments of the line, 7 of lancers, 7 of light horse, and 1 of guides. Each regiment has six squadrons, with a war strength of 150 horses per squadron. Of those squadrons, two are intended to be detached to the infantry divisions in war time, while the remaining four form the corps cavalry. The artillery comprises 10 regiments of field artillery, and 4 of garrison artillery, besides a certain number of coast and artificer companies. A regiment of field artillery consists of 10 batteries of 8 guns each, and 3 companies of artillery train. A regiment of garrison artillery consists of 15 companies. The engineers consist of a separate staff of officers, and 2 regiments, each divided into 4 companies of pontoniers, 16 of sappers, and 3 of engineer train. In addition to the above field organisation, every regiment of cavalry, infantry, artillery, or engineers has a depôt, which in peace time is maintained on *cadre* establishment only, but in war is completed from the surplus furlough men, and replaces casualties in the field army.

The total strength of the Italian active army on peace and war footing is approximately as follows:—

	Peace.	War.
Infantry, 80 Regiments, ...	128,000	245,000
Bersaglieri, 10 ,, ...	18,000	36,000
Cavalry, 20 ,, ...	18,000	21,000
Artillery, 10 Field Regiments, ...	11,000	21,000
,, 4 Garrison ,, ...	6,000	13,000
Engineers, 2 Regiments, ...	4,000	7,000
Train, 3 ,, ...	2,500	10,000
Staff Administration, &c., ...	3,500	8,000
	191,000	361,000

In war time this force is organised in 20 divisions, forming 10 army corps,—each corps comprised of 24 infantry battalions, 4 *bersaglieri* battalions, 2 cavalry regiments, and 10 field batteries, giving a fighting strength of 28,000 infantry, 2000 cavalry, and 80 guns. The corps and divisional organisation is not permanent in peace time; but the divisional staffs are kept up in those of 16 territorial and 4 active divisions maintained in peace.

The depôts and active militia, or second line of troops, are maintained in *cadre* only in peace time; the depôts on mobilisation are raised to a strength of 125,000, or a third of the active army. For the militia the *cadres* of 960 companies of infantry, 60 companies of *bersaglieri*, 10 of engineers, and 60 of artillery, are formed in peace time. On mobilisation these will give a force of about 250,000 men, of whom 200,000, with 40 batteries or 320 guns, could take the field if necessary. The local or "sedentary" militia is not organised in peace time, and is only called out in the last extremity, corresponding generally to the landsturm of Germany.

The kingdom of Italy is divided into 16 "territorial divisions," and these again are subdivided into "districts," of which there are 62, each comprising one or more of the 80 provinces of the kingdom. These districts are under the supervision of a colonel or lieutenant-colonel, whose duties correspond generally to those of the commander of the landwehr battalion districts in Prussia. He has under him a staff, and the *cadres* of from 1 to 6 companies, forming the depôts of the active army in peace time, and in war furnishing each the *cadres* for one militia battalion. He superintends the first instruction and forwarding of the annual contingent of recruits for the army, and the periodical training of the men belonging to the second class, who are on permanent furlough.

The Italian army is composed of very various materials, and in its reorganisation it has been the object of the Government to blend these together as much as possible. Going exactly contrary to the Prussian principle of localisation, the kingdom is divided into five "zones," and special arrangements are made to provide that each regiment shall receive recruits in due proportion from all five of these. The Piedmontese are a hardy, athletic race, superior, perhaps, to any in Europe in power of work and endurance of fatigue, privations, and hardships. They are temperate, intelligent, and combine a certain natural independence with a traditional respect for their princes and aristocracy, which makes them docile and amenable to discipline. The aristocracy of North Italy, like that of England, has always associated itself with the welfare and progress of the country, and deservedly kept the respect of all classes, and furnishes an excellent class of officers to the army. The southern Italian, on the other hand, is generally indolent, and incapable of much exertion, physical or mental; occasionally roused to enthusiasm, but wanting in steadiness of character; usually either bigoted and a slave to his priest, or a free-thinker, with little respect for any authority human or divine. Since enervated and luxurious Rome fell before the more vigorous northerner, the southern Italian has shown but little military spirit. Whether the amalgamation of the various races will raise the whole army to the level of the Piedmontese, or lower the old Piedmontese army to the level of the others, is a problem which can only be solved practically; but one may fairly hope that the new national life which is dawning on Italy will restore to its inhabitants something of the qualities which once made Rome mistress of the world.

Spanish Army.

Spain, once the proudest of nations, has been brought so low by years of misrule and anarchy that she can scarcely now be classed among the powers of Europe; and the army which under Charles V., the Duke of Alba, and the Constable of Bourbon had proved itself so formidable, has been reduced to a state of disorganisation that makes any detailed notice of it impossible. The martial spirit of old Spain, roused by the protracted struggle with the Moors, and fanned by the exploits of the Cid and the successes of Ferdinand of Castile, culminated in the reigns of Ferdinand and Isabella, and of their successor, Charles V. At the end of the 15th and beginning of the 16th century the Spanish army was renowned throughout Europe; while the discoveries of Columbus and the conquests of Cortes and Pizarro had extended her power and the fame of her arms to the New World. Gonsalvo de Cordova, Ferdinand's "great captain," was the creator of the Spanish infantry, which, modelled originally on that of the Swiss, soon eclipsed the latter, and became in its turn the model for other nations. More heavily armed than the Swiss, it trusted, like them, to massive formations and the irresistible weight of its attack. During the 16th century the Spanish infantry maintained its reputation, and it was not till the close of the century that its renown began to fade before the new school of Maurice of Nassau, and that the deep masses of the "Spanish brigade" gave way to the smaller and more mobile formations of the Netherland *ordonnance.* Under the disastrous reigns of the last princes of the house of Austria the army rapidly degenerated, and when Philip V. ascended the throne in 1700 it scarcely amounted to 15,000 men. During the 18th century it was largely augmented, and at the outbreak of the French revolution numbered about 120,000 of all arms. But though formidable in numbers, it was no longer so in quality; and throughout the long war with Napoleon it distinguished itself principally by its uniform ill success, and the haste with which it abandoned even the strongest positions. After the peace the army was reorganised, and efforts were made to improve its general condition. But the series of civil wars, or of risings in which the army was a principal actor, thwarted all such attempts. When Isabella was driven from the throne in 1868 the army espoused different sides, the bulk of the infantry joining Prim and the revolutionists, while the artillery and some of the *corps d'élite* remained faithful to the queen. In 1867 the total armed forces of the kingdom (including navy and colonial troops) were fixed at 200,000. The land forces in Spain itself amounted to 150,000, of whom 80,000 belonged to the regular army, and the remaining 70,000 were made up of *carabineros* or gendarmerie, *guardia civil,* and provincial militia. The law of recruiting passed in 1870 made all Spaniards liable to service on reaching the age of 20, and fixed the terms of service at four years in the ranks and two in the reserve. Substitution by exchange of numbers or by *remplaçants,* and exoneration by payment, were sanctioned—the price of the latter being fixed at £60. In 1872 the draft of a new military law was laid before the Cortes, by which substitution and exoneration were abolished, and the annual contingent required to complete the army was to be taken by position (according to age) on the lists, instead of by ballot. The term of service was fixed at seven years,—three to be passed in the army, two in the first reserve, and two in the second reserve; the first reserve being liable to be called out at any time to complete the active army, but the second reserve only in case of war, and by a vote of the Cortes. The abdication of King Amadeus, however, prevented tho carrying out of the contemplated reorganisation of the army.

The contrast between the conduct of the Spanish soldiers and of the Spanish people during the Peninsular war presents a curious problem. At the very time that the armies of Spain were dispersed on every occasion, often almost without firing a shot, the people were signalising themselves by the heroic defence of their towns, and by carrying on a desperate guerilla warfare that nothing could subdue. The Spaniard possesses many of the highest qualities of a soldier: he is hardy, temperate, individually brave, high-spirited, and independent; and though naturally indolent and idle, is easily roused, and capable of great heroism, as well as of sustained exertion. Yet this people, when brought together, form without exception the worst soldiers of Europe. They are impatient of discipline and restraint, and as easily discouraged as they are excited; and that mutual confidence in one another and in their leaders, which alone gives moral strength to a mass of men, is altogether wanting. How much of this may be due to the want of good leaders may be a question; but discipline must always be the basis of all military efficiency, and of discipline in the true sense of the word neither the soldiers nor the people of Spain have any idea

Portuguese Army.

The existing army dates from the Peninsular war, when a considerable force of Portuguese, at one time exceeding 60,000 men, was organised under Marshal Beresford. Trained and partly officered by English officers, it proved itself not unworthy of its allies, and bore its full share in the series of campaigns and battles by which the French were ultimately expelled from Spain. At the peace the army numbered about 50,000 infantry and 5000 cavalry, formed on the English model, and all in the highest state of efficiency. This force was reduced in 1821, under the new constitutional government, to about one-half. By the present law of military organisation, passed in 1864, the strength of the army is fixed at 30,000 men on peace footing, and 68,000 on war footing. The number under arms, however, has never approached this; and in 1869 the actual strength and composition of the army was as follows:—

	Officers.	Men.
18 Regiments (of 9 companies each) Infantry of the Line,	683	9218
9 Battalions of Rifles,	314	3468
8 Regiments of Lancers and Dragoons,	244	2253
3 ,, Artillery,	107	1278
1 Battalion of Engineers,	3	317
Staff and Administrative Troops,	194	106

The number of troops in the Portuguese colonies amounted to 8500 infantry and artillery, besides a reserve of 9500 men.

The army is raised partly by conscription and partly by voluntary enlistment, more than one-half being obtained by the latter method. Exemption may be purchased by the payment of a fixed sum, amounting to about £80. The time of service is eight years, of which five are spent in the regular army and three in the militia. The Portuguese have distinguished themselves rather by naval enterprise than as soldiers. Physically they are inferior to the Spaniards; but they are more amenable to discipline, and proved themselves far more valuable and trustworthy auxiliaries in the long Peninsular struggle

Dutch Army.

The military power of the "United Provinces" dates its rise from the middle of the 15th century, when, after a long and sanguinary struggle, they succeeded in emancipating themselves from the yoke of Spain; and in the following century it received considerable development in consequence of the wars they had to maintain against Louis XIV. In 1702 they had in their pay upwards of 100,000 men, exclusive of 30,000 in the service of the Dutch East India Company. At the beginning of the wars of the French Revolution the army had fallen to 36,000 men. In 1795 Holland was conquered by the French under Pichegru, and in the course of the changes which ensued the army was entirely reorganised, and under French direction bore its share in the great wars of the empire. In 1814 Holland was relieved of the yoke of France, and in the following year, her armies, under the gallant Prince of Orange, fought side by side with the British at Waterloo. At the peace of 1815 the Belgian provinces, subject before the war to Austria, were annexed to Holland, and the whole formed into a constitutional kingdom; but the union between the northern and southern provinces of the Netherlands was dissolved by the Belgian revolution of 1830, and in 1839 Belgium was finally acknowledged as an independent kingdom.

The military forces of the Netherlands consist of a home or regular army, a colonial army, and a militia. The regular army is in theory raised by conscription, five years being the term of service, but substitutes are allowed, and a great part of the force under arms are volunteers, the conscripts being drilled for ten months only, and then sent home on furlough, subject to six weeks' annual training. The colonial army is raised entirely by voluntary enlistment. The infantry of the regular army consists of 8 regiments of the line, each of 4 active and 1 depôt battalion, a regiment of guards, composed of 2 battalions of chasseurs and 2 of grenadiers, and a battalion of instruction. A battalion consists of 5 companies, of a peace strength of about 100 men, and a war strength of 200. The cavalry consists of 4 regiments of hussars, each regiment having 6 squadrons, viz., 4 field, 1 reserve, and 1 depôt. The strength of a squadron in time of peace is about 100 men, in time of war about 200. The artillery consists of 5 regiments, viz., 1 field, 3 garrison, and 1 of horse artillery. The field artillery regiment has 14 active batteries of 6 guns each, and 1 depôt company; the horse artillery has 4 active batteries and 1 depôt; the garrison regiments have each 14 companies, of which 1 is for torpedoes and 1 instructional. The engineers consist of a scientific staff, and 1 battalion of sappers and miners. The war strength of the Dutch army in 1872 was as follows:—

Staff and Administration,	175
Infantry,	43,010
Cavalry,	4,259
Artillery,	11,166
Engineers,	1,115
Total,	59,725

with 108 guns. The colonial army numbered about 28,000 men,—13,000 Europeans, and 15,000 natives.

The militia, or *garde civique*, is divided into two classes. the first, or active militia, numbering about 26,000, the second, or resting militia, about 61,000. The whole are organised in battalions according to locality. They are generally well clothed and armed, and of fair physique, but are very badly drilled. The men of the regular army are well drilled, and sturdy and robust, though rather small They have had the advantage of the services of many

Prussian officers as instructors, and a large camp of instruction is formed annually. The officers are mainly supplied from the military academy at Breda, and are of the upper classes; promotions from the ranks are very rare.

Belgian Army.

By a law passed in 1868 the strength of the Belgian army was fixed at 100,000 men on war footing, and 40,000 in time of peace. It is formed by conscription, to which every able-bodied male is liable on completing his 19th year. Substitution, however, is permitted, and substitutes or volunteers actually form a large part of the army. The annual contingent is 12,000 men. The period of service is eight years, of which two-thirds are passed on furlough; the actual time in the ranks has recently been increased from twenty-six to thirty months for the infantry; in the other services it is three years. The *infantry* consists of 1 regiment of carabineers, 3 of chasseurs, 1 of grenadiers, and 14 of the line. Each regiment has 3 field and 1 reserve battalion of four companies each, the latter in *cadre* only in peace time. The *cavalry* consists of 4 regiments of chasseurs and 4 of lancers, each of four field and one depôt squadron. The chasseurs form on mobilisation the divisional cavalry, the lancers the reserve cavalry. The *artillery* is formed in 4 regiments, and numbers 34 field and 6 reserve batteries of 6 guns each. The *engineers* are organised in 1 regiment of 3 battalions (four companies each), and 5 special companies, viz., two telegraph, one railway and one pontoon, and one of artificers. On mobilisation the army forms two army corps, each of two infantry divisions and a reserve of cavalry and artillery, and numbering 26 battalions, 16 squadrons, and 96 guns.

Besides the standing army there is a civic militia (*garde nationale*), available for the defence of the country in time of war. This force, which numbers 125,000 men without, and 400,000 men with the reserve, is formed of all citizens between 21 and 40 able to bear arms, but is only organised in the large towns and fortresses. In time of peace it is under the Ministry of the Interior, but in time of war under the Ministry of War.

The organisation of the Belgian army was subjected to a practical test in 1870, when it was suddenly mobilised and placed in observation on the frontier. The results were not satisfactory. The actual numbers fell considerably short of the estimated ones, and of the men present a large number were quite unfit for service. The number of officers was altogether insufficient, and the army was in many respects incompletely equipped. A bill for the reorganisation of the army, based on compulsory personal service, was introduced in 1871, and adopted in principle by an overwhelming majority of the commission appointed to examine it. But public opinion pronounced so decidedly against the abolition of substitution that Government gave way, and the bill was withdrawn. Ultimately, General Thiebault accepted the Ministry of War, and introduced a modified measure, which yielded the disputed point of substitution, and contented itself with additional guarantees for the character and quality of the substitutes, and reform in various branches of army administration. In a rich and enterprising commercial country like Belgium personal service would naturally fall peculiarly heavily; but, further than that, a not inconsiderable portion of the inhabitants are opposed to the maintenance of any standing army. The Belgians are not a military nation; the martial spirit which once made them a match for the trained soldiers of the most powerful and warlike kingdom of Europe, seems to have given place to mercantile instincts and industrial pursuits. The troops that fought at Waterloo alongside the British did little to raise Belgium's military reputation, some having deserted the battle-field in the midst of the conflict. The modern Belgian soldier is active, fairly intelligent, and a good marcher, but undersized, of inferior physique, and in most respects a bad copy of the French soldier.

Danish Army.

The Danish army, though small in numbers, has always been of excellent material, and the gallant stand made in 1864 against the overpowering forces of Austria and Prussia deservedly won the admiration of Europe. Since then she has reorganised her army on the principle of universal service; but has applied that principle in a manner peculiar to herself, and intermediate between the militia system of Switzerland and the three-years' system of Germany. By the law of 1867 every Danish citizen is liable to serve in the army or navy. Those who have been brought up as sailors, and have served at least eighteen months as such, are inscribed on the reserve lists of the navy; the rest serve in the army. Service commences at 22, except in the case of volunteers, who are allowed to join at 18. The period of service is fixed at eight years in the army, and eight years in the reserve or "reinforcement" (*forstaerkning*). The actual service with the colours is very short, and is divided into two periods. The first or recruit's course of instruction, which all must go through, lasts for six months in the infantry, five in the guard, field artillery, and engineers, and nine and a half in the cavalry. The second course lasts for nine months in the infantry, eleven in the cavalry, and one year in the artillery and engineers, and is confined to those who are considered insufficiently trained, to non-commissioned officers selected for promotion, and to a certain number, selected by lot, who are retained to complete the *cadres* and carry on garrison duties. In the infantry the bulk of the recruits are sent home after the first six months, about one-third to one-fourth remaining for the second term. On the other hand, the great majority of the cavalry, and almost the whole of the field artillery, are retained for the second period, and thus receive respectively twenty and seventeen months' training. For every three months of service in excess of the six months' course, one year is deducted from the period of service in the reserve. Those who were sent home after six months are called out again for a supplementary course of six weeks during their second year, which is passed at the camp of instruction at Hald, near Viborg, where from 8000 to 10,000 men are annually assembled for large manœuvres.

The Danish army is organised territorially, the kingdom being divided into five brigade districts, each of which is again subdivided into two regimental districts. A brigade consists of two infantry regiments, each of two line and one reserve battalion, and a cavalry regiment. The infantry regiments draw their contingent of recruits from the corresponding regimental districts, the two line battalions taking it by turns annually to receive and train the whole of the recruits for the regiment. The cavalry are recruited from the brigade districts, and the guard, artillery, and engineers from the kingdom generally. After remaining for four years on the lists of the line regiments, the conscripts are transferred for the remaining four years to the reserve battalions, in which they have to perform one course of training, the reserve battalions being mobilised during four weeks annually for the purpose. The Danish army thus consists of 1 regiment of infantry of the guard and 10 of the line, each of three battalions—two active and one reserve; 5 regiments of cavalry, each of three active and two reserve squadrons; 1 regiment of field artillery of twelve batteries, and 1 regiment of garrison artillery of two battalions; 1 regiment of engineers, of six active and three reserve companies, and 2 companies of military train. The total strength of the army, exclusive of reserves, is about 38,000 men; the number serving with the colours varies according to the time of year.

The Danish soldiers are, generally speaking, a fine body of men, of considerable physical power, and inured to hardship and rough living. They combine a good deal of northern stubbornness with the romance and martial feeling of the old Scandinavian. Nursed in old traditions and chivalrous legends, the quiet, hard-working Danish peasant has within him a vein of poetry and a sympathy for heroic deeds strongly contrasting with his outward demeanour. He still retains much of the character of the feudal ages —instinctive respect and attachment to his leaders, and implicit confidence in them; and in the army this feeling has been strengthened by the local character which the regiments have always had, officers and soldiers serving together for generations. The officers are all drawn from the upper class, and are as a rule highly-educated gentlemen; they are trained from an early age at the Academy at Copenhagen, where the languages and literature of all countries are taught, as well as purely scientific subjects, and undergo strict examinations before they pass as cadets.

Swedish and Norwegian Army.

Although the crowns of Sweden and Norway are now permanently united, each country retains its own government, constitution, and laws; and the military forces of the two countries are separate and differently organised. The Swedish army is composed of three distinct classes,—the "värfrade," or enlisted troops, to which belong the royal guards, one regiment of hussars, the artillery, and the engineers; the "indelta," or national army, paid and kept by the landowners, each of whom furnishes a certain number of men, to whom, besides a small annual pay, a cottage and a piece of land are allotted during the period of service; and thirdly, the "beräring," or conscription troops, drawn by annual levy from the male population between the ages of 20 and 25 years. The "indelta" are called out for a month's training annually in time of peace. Besides the above, there is a Gothland militia force of 30 companies of infantry and 3 batteries of artillery, numbering about 8000 men; these, however, are not compelled to serve beyond the confines of the isle of Gothland, and have a separate command. The royal guards number 2240, the line (under which is included the "indelta") about 25,000 infantry, 5000 cavalry, 5000 artillery with 234 guns, and 1000 engineers. The "beräring" amount to about 95,000 of all arms. The Swedish troops are physically the finest in Europe,—powerful, hardy, and brave, and retaining much of the old Scandinavian heroic spirit; and, though strictly a militia only, their peculiar aptitude for all warlike exercises would make them formidable antagonists, even to the best trained armies. Few nations have so brilliant a military history. Under Gustavus Adolphus in the Thirty Years' War, and later under the heroic but insatiate Charles XII., they achieved a reputation almost unrivalled in Europe; and their armies and tactics served for many years as models to the great military powers.

The military forces of Norway are differently organised, and though divided into line and militia, are in fact purely a militia force. By the law of 1867 all young men past the age of 21 are liable to the conscription, with exception of the inhabitants of the three northern provinces, who are free from all military service. Actually the troops are raised partly by voluntary enlistment and partly by conscription. The term of service is for ten years, divided into three in the line, four in the reserve, and three in the militia or "landvaern." The *cadres* of the army are formed entirely of volunteers. The young men raised by conscription are required to go through a recruit's course of forty-two days, and subsequently an annual training of twenty-four days. On the 1st January 1872 the troops of the line numbered 13,000 men, the reserves 19,000, and the landvaern 11,000. The landvaern are only liable to service within the frontiers of the kingdom.

Swiss Army.

The inhabitants of Switzerland were always a hardy and independent race, but their high military reputation dates from the middle of the 15th century, when the comparatively ill-armed and untrained mountaineers signally defeated Charles the Bold of Burgundy and the flower of the chivalry of Europe in the battles of Granson, Morat, and Nancy. The Suabian war, towards the end of that century, and the Milanese war, at the beginning of the following one, added to the fame of the Swiss infantry, and made it the model on which that arm was formed all over Europe. The wealthier countries vied with each other in hiring them as mercenaries, and the poor but warlike Swiss found the profession of arms a lucrative one. Whatever discredit may attach to the soldier who sells his services to any country or cause, and fights for money alone, the Swiss at least have done much to redeem the position by their unswerving loyalty to their employers. The devoted faithfulness of Louis XVI.'s Swiss guard is proverbial, and has been commemorated with just pride by their countrymen. The French Revolutionary armies overran Switzerland, as they did all the small neighbouring states, and during Napoleon's career she had to submit to his rule, and furnish her contingent to his armies. On the fall of Napoleon she regained her independence, and returned to her old trade of furnishing soldiers to the sovereigns and powers of Europe. Charles X. of France had at one time as many as 17,000 Swiss in his pay; Naples and Rome had each four regiments. The recruiting for these foreign services was openly acknowledged and encouraged by the Government. The young Swiss engaged usually for a period of four or six years; they were formed in separate regiments, officered by countrymen of their own, and received a higher rate of pay than the national regiments; and at the close of their engagement returned with their earnings to settle down on their paternal holdings. A series of revolutions, however, expelled them from France and Italy, and recently the advance of liberal ideas, and the creation of great national armies based on the principle of personal service, has destroyed their occupation. Switzerland is now remarkable in a military sense as being the only country that maintains no standing army; and the fact that, with an annual expenditure of only £200,000, she shows a force of 200,000 men, has made her military institutions the study of economists and the model for many would-be military reformers.

The 13th article of the constitution of 1848 forbids the maintenance of a standing army within the limits of the confederation; but every citizen is required to bear arms for the defence of the country, and for this purpose a certain military training is given at all schools. The actual forces of the republic consist of a militia divided into three classes,—the "auszug" or *élite*, the reserve, and the landwehr. The strength of the *élite* is fixed at 3 per cent. of the population, and that of the reserve at 1½ per cent.; the landwehr includes all who have passed the *élite* and reserve up to the age of 44. The total service is limited to twenty-five years. Within these conditions the cantons are allowed to raise their contingents and distribute the service as they please; and it thus happens that service in the *élite* lasts for five years in some cantons, and for fourteen years in others. Exemption from service is granted to certain Government and public officials, to the clergy, surgeons, &c.; all other citizens become liable on attaining the age of 20. No substitutes are allowed, and any one rejected for bodily infirmity, or exempted from any cause, is required to pay a small tax.

The strength of the armed forces of Switzerland was given as follows in 1872:—

	Auszug.	Reserve.	Landwehr.	Total
Staff	...	...	...	841
Infantry	66,649	39,078	54,334	160,061
Rifles (Scharfschützen)	6,001	3,364	4,616	13,981
Cavalry	1,913	1,086	1,571	4,570
Artillery	8,262	5,350	4,643	18,255
Engineers	1,245	1,059	743	3,047
Administration	299	129	74	502
	84,369	50,066	65,981	201,257

Of these, however, the landwehr exist on paper only, and may be left out of consideration; and the available force is estimated at about 105,000, of whom 70,000 belong to the "auszug," and 35,000 to the reserve.

The infantry are armed and equipped by their cantons, the recruit himself having to bear a portion of the expense. Before being placed on the rolls of the "auszug" he has to undergo a training of four weeks for the line, or five weeks for the rifles; and subsequently an annual training of eight days while in the *élite*, and six days in the reserve. Practically, however, the *élite* are commonly called out every second year only, and the training of the reserve is often omitted altogether The cavalry, artillery, and engineers have a recruit's course of six weeks, and an annual training of (nominally) a fortnight; but in practice the latter has been reduced to eight days every second year. The cavalry resemble our yeomanry, consisting of a wealthier class of men, who find their own horses; the engineers are selected from men following suitable trades. The whole army is formed in six divisions, and annually one or two of these are assembled for divisional manœuvres. A handsome federal barrack for infantry and cavalry and a permanent instructional establishment exist at Thun. Officers are required to go through a six weeks' course at this federal school, and to attend one course of recruit training on appointment. The nomination of officers, and promotions up to the rank of captain, are made by the cantonal governments; promotion to the higher grades and appointments to the staff by the federal authorities, though usually on the recommendation of the cantons. Candidates for the staff are required to go through a two months' course at a staff school which is annually opened for the purpose.

A study of the military system of Switzerland will at once explain its apparent cheapness. The expenditure shown in the federal budget is only a portion of the real cost of the army; to it must be added the expenses borne by the cantons and by the men themselves. The actual cost is estimated by the best authorities at £533,000 per annum, or about £5 per head for an effective strength of 105,000 men. In England the annual cost of the militia is about £8 per head, of the volunteers £3. The Swiss so-called army may take its place between our militia and volunteers. The men are less trained than our militiamen, but are generally better educated and of a more intelligent class. They show at least as much independence as our volunteers, and many things of acknowledged necessity are left undone, simply because the men will not do them. The officers are in all respects inferior, and that class who have previously seen service in the army is wanting. In equipment the army is far behind our auxiliary forces, and an attempt made in 1872 to improve its organisation generally, and give the federal authorities more power, was successfully resisted by the cantons. During the war of 1870–71 five divisions of the Swiss army, amounting in all to about 37,000 men, were mobilised and assembled on the frontier; and superficial observers were enthusiastic in their praises of the organisation and efficiency of this citizen army. But their own commander reported that there was "incredible friction in the mechanism of the whole force;" that many of the battalions were in the lowest condition of discipline and efficiency; and that "to march against an enemy with such troops as these would indeed be a bold enterprise;" and urged that "it would be far preferable to have an army weaker in point of numbers, but of better quality." What becomes of such forces when opposed to a real army has been abundantly illustrated by the history of the French *gardes mobiles* in the war of 1870. Switzerland exists by the sufferance of her powerful neighbours, and her military institutions are suited to such conditions, but not to a power that relies on itself for its independence.

Turkish Army.

The Ottoman empire, whose power at one time seemed to threaten the very existence of the Christian states, has long lost her terrors, and her military institutions are now studied rather to see what elements of resistance to foreign aggression she still possesses, than for the part she may play in European politics. Her armies have lost their peculiar character and constitution, and with it much of the spirit which once made them formidable. In the early days of her rising power every Osmanli was a soldier; and the whole nation was animated with that martial fanaticism that was the secret of her strength. As her conquests extended, her warriors were rewarded with grants of land, and a system of military tenure arose resembling the feudal system of Western Europe. And though the Osmanli retained his simple habits and warlike spirit, the unfitness of such a militia for prolonged operations soon led, as in the Christian states, to the establishment of a more permanent force. Sultan Amurath I. in 1360 first formed a bodyguard of Christian captives; and this force, highly privileged and rewarded, soon swelled to large dimensions. Such was the origin of the janissaries, the earliest standing army in Europe, and for long the scourge and terror of the neighbouring Christian states. Like most proselytes, they were more fanatical even than the genuine Osmanli; and this, added to a permanent organisation, made them for a time almost invincible. But success and indulgence produced their usual results, they became overbearing, corrupt, and formidable only to their own country. From being the sultan's slaves they became his masters, and the history of Turkey shows a long list of rulers appointed, deposed, or murdered by the janissaries. Two attempts to break their power failed disastrously. But Sultan Mahmoud II. was not daunted by a first failure, and when in 1826 he commenced his reorganisation of the army, and the janissaries again rose against him, they found him prepared. The new troops remained faithful, and in a terrible three days' struggle, in which 20,000 of their number were killed, the janissaries as a body were annihilated. Mahmoud now hastened to reconstitute his army on European models; but while his measures were still in embryo he found himself involved in a war with Russia, and though the newly-raised troops behaved with gallantry, the war soon took an unfavourable turn, and ended disastrously for Turkey with the humiliating peace of Adrianople. The reforms instituted by Mahmoud were, however, carried on vigorously by his successor, Abdul Medjid, and form the basis of the present military institutions of Turkey.

As now constituted, the Turkish forces consist of the "nizam," or standing army; "ichtjat," or first reserve;

"redif," or second reserve; "hijade," or landsturm; and a certain number of irregular levies.

Although in principle every one is liable to service, the army is recruited entirely from the Mussulman population, Christians and others being exempted on payment of a tax called the "bédel." The capital, the island of Crete, and certain frontier districts, are by ancient privilege exempt both from service and from the tax. The burden of the conscription therefore fails on a comparatively small proportion, considerably less than one-half of the population. The actual conscripts, however, are not numerous. A considerable proportion of the army is raised by voluntary enlistment, the pay being sufficiently high to attract poor Mussulmans; and as personal substitutes, or exemption on payment of a fixed sum (in which case Government finds the substitute), are both allowed, all possessed of any means can and usually do escape service. The period of service is fixed at twenty years,—four in the ranks, two in the "ichtjat," six in the "redif," and eight in the "hijade." The strength of the standing army remaining at 150,000 men, the annual levy is fixed at one quarter of this, or 37,500; and it is estimated that this will give 70,000 (two years' contingents, deducting casualties) in the "ichtjat," about 200,000 in the "redif," and 250,000 in the "hijade," or a total of 670,000 men. Practically, however, these numbers would never be attained, and a great part of the necessary organisation exists only on paper.

The standing army is divided into six army corps, corresponding to the six military districts or "ordus" into which the empire is divided; each army corps consists of 6 to 7 infantry regiments, 6 or 7 rifle battalions, 2 to 7 cavalry regiments, and 1 artillery regiment. There is no divisional or brigade organisation in peace time, the regimental commanders communicating direct with the corps commanders; but in war time brigades of two regiments and divisions of two brigades are formed. The *infantry* of the standing army consists of 41 line regiments of 3 battalions each, and 38 rifle battalions, or a total of 161 battalions. A line or rifle battalion has 8 companies, and a normal or war strength of 33 officers and 800 men; the peace strength is variable, being reduced by furloughs granted at the discretion of the corps or regimental commander, and seldom exceeds 400. Their regimental organisation, parade formations, and drill, are copied from the French. The infantry uniform, which until recently was also on the European pattern, is now more national, and consists of an open blue jacket, an ornamental waistcoat, leather sash, wide Turkish trousers, yellow lace boots, and fez cap. The *cavalry* numbers 25 regiments, all light cavalry, each of 6 squadrons, and numbering on war establishment 42 officers, 914 men, and 856 horses. The four centre squadrons are armed with lances, the two flank ones with breech-loading carbines; all carry sword and revolver besides. The uniform is an open jacket and waistcoat like that of the infantry, but differently laced; the saddle is that known in Austria as the "Hungarian" saddle.

The *artillery* consists of 6 regiments of field artillery, attached to the several army corps, a reserve artillery regiment, and 7 regiments of garrison artillery. A field artillery regiment consists of 15 batteries of 6 guns each; the reserve artillery regiment is similarly organised, and acts as a depôt to the others. The garrison regiments are distributed to the different fortresses; they are formed of 4 battalions of 3 companies, and have a war strength of 2040 men, but in peace scarcely number a third of that. The fortification corps, or corps of engineers, belongs to the artillery, and consists of 2 battalions of 4 companies each. The artillery has always been the best organised and most highly trained branch of the Ottoman army. Mahmoud paid special attention to it, and it was the fidelity of that branch that gave him the victory in the struggle with the janissaries. Foreign officers, Germans especially, have always been largely employed in it, and by their exertions have brought it to a state of efficiency contrasting most favourably with the rest of the army.

The following gives the actual strength of the "nizam" or standing army in 1870, and its estimated strength on war establishment (combatants only):—

	Actual strength.	Estimated war strength.
Infantry	71,000	128,000
Cavalry	16,000	20,000
Artillery (guns)	396	552

After completing four years' service in the ranks, the Turkish soldier is passed into the "ichtjat," or first reserve, for two years, during which he is liable at any time to be recalled, and cannot leave his district without permission. The men of this first reserve, estimated at 70,000, are intended to form separate battalions, but are in all respects available for service like the standing army. Actually a large number would be required to complete the "nizam," and the *cadres* and officers for these reserve battalions only partially exist. A few such battalions were, however, formed at the time of the Yemen expedition in 1870. After two years in this first reserve, the soldier is passed on to the "redif," or second reserve. The "redif" can only be called out in war time, and is not liable for service except within the country. It is divided into two levies, each of three years' contingents, and forms separate regiments and batteries; and it is proposed to form these into army corps corresponding to the existing corps of the standing army, and consisting each of 6 infantry regiments, 6 rifle battalions, 3 cavalry regiments, and 1 artillery regiment of 6 batteries. But this organisation exists on paper only, and it is very doubtful if the necessary *cadres* and officers would be forthcoming. Lastly, after six years in the "redif," the man is passed on to the "hijade," or landsturm, for eight years; but this force, though liable to be called out in war, is not organised even on paper.

The *irregular troops*, which are raised in war, and at one time formed a principal element of strength, are of two kinds,—paid troops (Bashi-Bazouks) and volunteers (Spahis, Bedouins, &c.) The former are usually raised by contract, the governor of a province receiving orders to raise a certain number, and being supplied with the necessary funds, and thereupon contracting with such chiefs or adventurers as undertake to furnish the men at the lowest cost. Most of the money finds its way into the pockets of the governor or contractor, and but little goes to the Bashi-Bazouks. In the last war between Russia and Turkey (1853–55) 20,000 to 30,000 of these were raised, for the most part ill-armed and worse disciplined infantry; but most of them were disbanded before the close of the war. The volunteers, on the other hand, though deficient in organisation, are zealous Mussulmans and brave soldiers. They come mostly from the wild border tribes, in small bodies, under their own chiefs and beys, and furnish a very valuable irregular cavalry.

The Turkish soldier of the present day is generally docile, faithful, temperate, and capable of undergoing great hardships or fatigue. The familiar terms on which the subordinate officers mix with the men would be considered subversive of discipline in any other army, but do not appear to be so in the Ottoman army, and serious military offences are rare. When well commanded, he has shown himself capable of great personal devotion and even heroism, but of a passive rather than an active character. Naturally calm and rather apathetic, he seems to have retained that fatalism which is a special characteristic of his religion, but to have lost the fiery zeal that distinguished his ancestors, and made them, whether individually or as a nation, such formidable assailants. It may be questioned whether, in a purely military aspect, Mahmoud did not lose more than he gained by the destruction of the janissaries and reorganisation of his army on modern models, and whether any amount of drill and science will compensate for the old fanatical spirit. But some such reforms were necessary; Turkey could not continue to hold a place in Europe, yet live the life of an Eastern nation and of an age long past. Her new armies have showed themselves formidable on many occasions; her artillery promises to rival that of most Western nations; and if the Osmanli character is in some respects ill-suited to the scientific and far-seeing character of modern warfare, it still retains enough of its old religious fanaticism to make her more than ordinarily dangerous in a defensive and, as it would seem to her, a holy war.

In a notice of the military forces of Turkey mention must be made of her vassal states, Egypt and Tunis, each of which is bound to furnish an auxiliary contingent in war. The military forces of Tunis and Tripoli are too insignificant to require special notice: her contingent is from 2000 to 4000 infantry, 1000 cavalry, and 8 guns, and during the Crimean war she did actually send about 4000 men to the seat of war in Asia Minor. Egypt is now pledged to furnish an army corps of 30,000 men complete with cavalry and guns. In the Crimean war she furnished first one and afterwards two divisions, amounting to about 21,000 men; and during the insurrection in Crete she furnished a contingent of 10,000 men. The Egyptian army is almost the creation of its present ruler, Ismail Pacha, who on his accession found only two infantry regiments and a few detachments of irregulars. It now consists of 15 infantry regiments of 3 battalions each, 3 rifle battalions, 4 cavalry regiments, 2 regiments of field artillery, and 3 of garrison artillery, and 1 battalion of sappers; and numbers on war strength about 52,000 infantry, 2500 cavalry, and 144 guns. The peace strength is little more than half this. These troops are all organised and drilled on European principles, mainly after French models. Many of the highest officials are actually old French officers. In addition to these, Egypt maintains a force of about 8000 *sandschaks* or irregular troops, who receive a higher rate of pay, but are required to arm, clothe, and feed themselves, and are permanently stationed on her frontiers. In case of war Egypt can raise about 10,000 irregular cavalry among the tribes that are subject to her.

American Army.

The army of the United States of America is the last that calls for notice. Threatened by no powerful or warlike neighbours, the United States are saved from that ruinous competition in armaments which presses on the industry of European countries. The American army is little more than a police force, of which a few regiments serve as a reserve to the civil power in the great towns, while the rest are dispersed in small posts along the frontiers or among the Indian districts. By an Act of 1870 its strength was limited to 30,000 men. It consists of 10 regiments of cavalry, each of 12 companies or troops; 25 regiments of infantry, of 10 companies each; 5 regiments of artillery, and one engineer battalion. The cavalry, broken up in small detachments, partake more of the character of mounted police than of that of European cavalry. They are armed with swords and breech-loading or repeating rifles, and trained to act on foot as well as on horseback; and the whole cavalry drill is assimilated as closely as possible to that of the infantry. The infantry are organised after the old English fashion in single battalion regiments of 10 companies. The army is raised entirely by voluntary enlistment; the term of service is three years, but it is now proposed to extend it to five, and re-engagements are encouraged. Two regiments of cavalry and three of infantry are composed of negro soldiers, but commanded by white officers. The officers of the army are furnished by West Point Academy, a military school equal to any in Europe. The course of instruction lasts four years, and includes all subjects of general education besides purely professional ones. West Point is sought by young men of the best families in America, and the number educated there considerably exceeds the requirements of the army. It is thus the means of spreading a certain military education throughout the country, and it was to this West Point training that the Southerners owed the large number of excellent officers that were found in their ranks in the war.

For military purposes the territory of the United States is divided into ten departments, and those grouped into four military divisions: the South, comprising the departments of the South and of Texas; the division of the Missouri, comprising the departments of Dakota, the Platte, and Missouri; the division of the Pacific, comprising the departments of Columbia, California, and Arizona; and the division of the East, comprising the departments of the East and the Lakes.

By the constitution of September 1787 the President is Commander-in-Chief of the army and militia of the Union, and Congress has power to raise and support armies, to make rules for their government and regulation, and to provide for calling forth the militia to execute the laws of the Union, suppress insurrections, and repel invasions. The Articles of War, by which all troops when mustered into service are governed, were enacted in 1806, and are a close but somewhat improved copy of those in force in the English army, and much of their army regulations is identical with the old general regulations and orders of the royal army.

The military history of the United States is as strange as the rise and rapid growth of the nation. In 1790 the rank and file of the army, as fixed by Act of Congress, amounted to 1216 men; and in 1814 an English expedition of only 3500 men was able to seize and burn Washington, the capital of a country which even then numbered eight millions of inhabitants. In 1861, at the commencement of the war of the secession, the whole regular force amounted to only 14,000 men. In April of that year the President called out 75,000 volunteers for three months to defend the capital, which was threatened; and in May a further call for 42,000 was made. In July two calls for 500,000 each were authorised by Congress, and as even this vast force proved insufficient for the gigantic struggle which America had now embarked in, it was found necessary to introduce the conscription. In October 1863 a levy of 300,000 men was ordered, and in February 1864 a further call of 500,000 was made. Finally, in the beginning of 1865 two further levies, amounting in all to 500,000 men, were ordered, but were only partially carried out in consequence of the cessation of hostilities. The total number of men called under arms by the Government of the United States, between April 1861 and April 1865, amounted to 2,759,049, of whom 2,656,053 were actually embodied in the armies. If to these be added the 1,100,000 men embodied by the Southern States during the same time, the total armed forces reach the enormous amount of nearly four millions, drawn from a population of only 32 millions,—figures before which the celebrated uprising of the French nation in 1793, or the recent efforts of France and Germany in the war of 1870-71, sink into insignificance. And within three years the whole of those vast forces were peaceably disbanded, and the army had shrunk to a normal strength of only 30,000 men. (G. P. C.)

ARNAUD, Henri, the celebrated pastor, military leader, and historian of the Vaudois, was born, in 1641, at La Tour, or La Torre, in Piedmont. He is said to have served under William of Orange, and it is probable that he received pecuniary assistance from that prince in his efforts to restore the exiled Vaudois to their native valleys. Owing to the cruelties of Victor Amadeus of Savoy, from two to three thousand of these Vaudois had been forced to take refuge in Switzerland and the states along the banks of the Rhine; and twice they ineffectually attempted to return to their home. But the English Revolution of 1688, and the accession of William of Orange to the throne, encouraged Arnaud to make a grand effort. Concentrating about 900 followers in the great forest of the Pays de Vaud, he remained in concealment for some time; and at last embarked with them on the Lake of Geneva on the night of 16th August 1689. By September 16 they had entered the valley of San Martino, after hard fighting with the French and Savoyard troops that harassed and opposed them. Being now, however, in danger of attack from about 20,000 French and Piedmontese troops, they were obliged to repair to the lofty table-land of the Balsille, which they fortified with such skill as to be able to withstand the fiercest attacks of the enemy, repeatedly renewed through the whole winter. A general assault on the Balsille (2d May 1690) by about 22,000 French was an utter failure, resulting in the decimation of the enemy, without the loss of a single man to Arnaud. Not caring to hazard a renewal of the assault the garrison withdrew from this stronghold to Angrona, where, just when all chance of further escape seemed impossible, they learned that hostilities had broken out between France and Piedmont, and that their king, who had persecuted and expelled them, was now ready to receive them with open arms. Thus ended the "glorieuse rentrée des Vaudois dans leurs vallées," effected, according to their own account, with a loss of only 30 men, while they made out that the joint losses of the French and Savoyards fell little short of 10,000 men. For a while the Vaudois were allowed to remain in peaceful possession of their ancient homes; but when the war of the Spanish Succession broke out, Arnaud and his followers took part in the combination against France, and rendered the allies effectual service. When the war came to a close, the ungrateful king of Piedmont once more joined the French monarch against his own subjects, and complied with the demands of that prince, that the Vaudois should be expelled from some of their valleys. The exiles, amounting in all to about 3000, found an asylum in Würtemberg. Arnaud, who had invitations from William III., and might have spent the remainder of his days in ease and honour in England, chose rather to continue the pastor of the exiles in the village of Schönberg, and wrote, in his retirement, the *Histoire de la glorieuse Rentrée des Vaudois dans leurs Vallées.* It was printed in 1710, and dedicated to Queen Anne, and has been twice translated into English. Arnaud died at Schönberg in 1721, and every memorial that he left behind him was long cherished by his followers and their posterity.

ARNAUD, or ARNOLDUS, DE VILLA NOVA, a physician, alchemist, and astrologer, who lived at Paris about the end of the 13th and beginning of the 14th centuries. The discovery of the three principal acids,—sulphuric, nitric, and hydrochloric,—has been attributed to him, but Hoefer (*Hist. de la Chimie.*, t. i. p. 385) has shown that these had all been discovered long before his time. His works, with a life prefixed, were printed at Lyons, first in 1504, folio, and again with the notes of Nicholas Tolerus, in 1520, folio; also at Basel in 1515 and 1585.

ARNAULD, Angélique (called Angélique de Saint-Jean), niece of the first or great Angélique, was born in 1624. She was educated at Port-Royal, and took the veil in her twentieth year. In 1653 she was made sub-prioress. During the persecution of the Jansenists, from 1661 to 1664, she was the chief support of the nuns in their resolute refusal to sign the Formulary of Alexander VII. Along with some others she was put into confinement, and, even after permission had been given to return to Port-Royal, they continued to be under the close surveillance of soldiers, who were not withdrawn till 1669, after the "peace" edict of Clement IX. In 1678 Angélique was elected abbess, which office she continued to hold till her death in 1684. She has left several works, in particular the *Mémoires pour servir à l'histoire de Port-Royal, &c.*, 3 vols., 1742, which throw much light on the life of her great aunt. See Arnauld, Jacqueline Marie.

ARNAULD, Antoine, one of the greatest French theologians and philosophers, was born at Paris, Feb. 8, 1612. His father was the most famous advocate of the time, and had gained special distinction by his defence of the university against the Jesuits in 1594. Of his large family, Antoine was the twentieth and youngest child. As he was at first destined to follow his father's profession, he turned his attention to legal studies as soon as he had completed the usual course of education at the colleges of Calvi and Lisieux. But the earnest advice of his mother, a deeply religious woman, who afterwards became an inmate of Port-Royal, induced him to give up the profession of a lawyer and to engage in the service of the church. He received his first instructions in theology from Lescot, confessor of Richelieu, but his teacher's influence over his mind was greatly weakened by the study of some works of Augustine, which, at the request of his mother, had been recommended to him by St Cyran. The thesis which he presented for the degree of bachelor in 1635 showed manifest traces of Augustine's influence, and gave great offence to Lescot. Arnauld now entered the Sorbonne, and from 1638 to 1640 professed the courses of theology and philosophy requisite for a licence. In 1641 he was ordained priest, and took his degree of doctor. After being twice rejected on formal grounds, or, perhaps, from the hostile influence of Lescot, he was, in 1634, admitted a member of the Society of the Sorbonne. In 1641 his mother died. Her last words, in which she implored him to hold stedfastly by the truth, made a deep impression on his mind. He gave up several benefices which he had obtained, and resolved to devote himself with all his soul to the defence and propagation of what he believed to be the truth. Between 1641 and 1643 he composed a treatise in two vols, *De la Necessité de la Foi* (not published till 1700), and another, *Théologie Morale des Jésuites.* In August 1643 he published his famous work, *De la Fréquente Communion*, expressly directed against the Jesuits, who held that the mere mechanical reception of the sacraments was sufficient, and that previous preparation and actual repentance were of secondary importance. They had even gone the length of saying, that the more a man sinned the more frequently and boldly should he approach the table of communion. Arnauld's book was sanctioned by many doctors of the Sorbonne, and by several bishops and archbishops. It was denounced by the Jesuits, one of whom, by name Nouet, preached against its heretical tenets, and called Arnauld an heresiarch worse than Calvin or Luther. This, however, carried matters too far, the Sorbonne and the bishops, who had given their sanction, were implicated in such a condemnation, and, by their influence, Nouet was compelled to retract. But the Jesuits insisted that the work must be judged at Rome, and laid special stress on a sentence in the preface, due not to Arnauld, but to De Barcos. This sentence they held to be adverse to the Papal supremacy, and they so wrought upon Mazarin as to obtain from him a decree commanding Arnauld and De Barcos to repair to Rome. Such intense excitement and indignation were roused by this decree, which struck a blow at the freedom of the French Church, that Mazarin apologised and withdrew it. De Barcos, who had made preparations for his journey to Rome, now learned that the Jesuits were forming bolder and more dangerous designs against Arnauld and himself. He withdrew into concealment and warned Arnauld, who followed his example. The book was examined at Rome and defended by Bourgeois, a doctor of the Sorbonne, and only the one sentence in the preface fell under Papal censure.

Scarcely was this controversy over, when a fresh cause of trouble arose. In 1640 appeared the *Augustinus* of Jansen, bishop of Ypres, the great object of which was to show that the doctrines of Augustine on grace, freewill, and redemption, were opposed to those of the Jesuits, which were really semi-Pelagian. This work fell under Papal censure in 1642, in the bull *In eminenti*, which condemned it as a revival of the errors of Bajus. Arnauld, in 1643, wrote some observations and considerations on the bull, and in 1644–45 a first and second apology for Jansenius. For a time there was little opposition made by the Jesuits, and Arnauld, besides superintending at Port-Royal, occupied himself in translating into French some of Augustine's works, and into Latin his own treatise *De la Fréquente Communion.* At last, in 1649, one Cornet proposed to the Sorbonne seven propositions which he maintained to be heretical. Of these, five were drawn from the *Augustinus* of Jansen. The other two propositions were allowed to drop, and after much controversy the five were condemned by a Papal bull in 1653. Two years later the duc de Liancourt, whose chaplain was a Jansenist, and whose grand-daughter was an inmate of Port-Royal, was refused absolution by a Jesuit confessor unless he dismissed his chaplain and withdrew his grand-daughter from the heretical community. Arnauld wrote two letters upon this affair—the first anonymously, the second signed with his name, and addressed to the duc de Luines. In this second letter it was stated,—1st, that the fathers of the church exhibit to us, in St Peter, a saint who was deficient in saving grace; 2d, that the five heretical propositions were not contained in the *Augustinus.* This second statement contains the celebrated distinction of the questions "de jure" and "de facto." As a matter of right,—of faith,—the propositions were heretical, wherever they occurred; but as a matter of fact, they were not to be found in Jansen's book in the sense ascribed to them by his opponents. The Jesuits held that this was really a rejection and defiance of the Papal bull; and, in 1656 they prevailed on the Sorbonne to expel Arnauld, deprive him of his doctorate, and pass a decree to the effect that all future members of their body must sign the censure. Arnauld's defence against this decree was undertaken by Pascal, who, in his brilliant *Provincial Letters*, brought down the dispute to the level of public comprehension. Arnauld continued to live in retirement, and, in company with Nicole, composed the valuable Port-Royal treatises on grammar, logic, and geometry. In 1668 the peace of the church allowed him to emerge from his retirement. He was received with great honour, and devoted himself to defending Jansenism from the imputation of leading to Calvinistic heresy. To refute this calumny he had already published (in 1664) the work known as the *Petite perpetuité de la Foi;* and in 1669 appeared the first volume of the *Grande perpetuité de la Foi de l'Eglise sur l'Eucharistie,* which was continued in 1671 and 1674. This great defence of transubstantiation, though appearing under Arnauld's name, was mainly the work of Nicole. Arnauld followed it up with several polemical writings against the impious and immoral tendencies of Calvinism. During this time also he was engaged in his elaborate assault on the moral doctrines of the Jesuits, the first volume of the *Morale Pratique des Jésuites* appeared in 1669, and seven other volumes followed at intervals up to 1694.

In 1679 Arnauld was again compelled to conceal himself. He fled from France, and, pursued by the enmity of the Jesuits, went from Mons to Tournai, thence to Ghent, from Ghent to Brussels, and, after having been driven into Holland, settled at Brussels from 1682 to 1690. In 1690 he was again compelled to leave his refuge, but, after wandering about for four years, returned to Brussels, where he died on the 8th August 1694. He was buried in secret, and his heart was sent to be interred at Port-Royal. During the last years of his life his activity never slackened. While continuing the large works already begun, he entered on a long philosophical discussion with Malebranche, in the course of which he published his treatise *Des Vraies et des Fausses Idées*, 1683, the *Réflexions Philosophiques et Théologiques*, 1685, and a number of letters to Malebranche. He was also engaged in keen controversy with his old friends Nicole and Domat. Of his unwearied activity a characteristic illustration is his reply to Nicole, who urged him to rest from his labours. "Rest!" replied he, "shall we not have the whole of eternity to rest in?"

As a theologian Arnauld stands high among French writers, not only from the matter of his works, but from their style. He was the first to introduce a pure and grammatical mode of composition, and to lay aside the infinitely numerous subtleties of the preceding centuries. His writing is singularly vigorous and clear. His philosophic reputation rests on his doctrine of external perception and his work on logic. He was perhaps the first to oppose the theory of representative ideas, or of perception through the ideas of objects, which ideas exist apart from the perceived thing and the perceiving mind. According to him, we perceive things in ideas, but the idea is the same as the perception; we have, in short, only a modification of the mind, conditioned by, or containing objectively, the thing itself. This mental state is subjective, but with an objective reference; to mark the first characteristic, it may be called perception, to mark the second, idea. In many points Arnauld anticipates Reid's objections to representative ideas, but their theories of perception can scarcely be regarded as identical. The *Art de Penser*, familiarly known as the Port-Royal Logic, is the best specimen of the logic of the Cartesian school. It is fresh, clear, and instructive, not overburdened with the useless paraphernalia of scholastic forms, but rich in practical precepts and examples. It is, however, in the main popular, and falls far short of a scientific presentation of the theory of thought. It has been frequently republished in France, and has been much used both in England and in Germany. The complete edition of Arnauld's works, with life by Larrière, is in 45 volumes, 4to, Paris and Lausanne, 1775-1783.

ARNAULD, Jacqueline Marie (better known by her religious name, Marie Angélique de Ste Magdeleine), born 8th September 1591, was the second daughter of Antoine Arnauld, the celebrated advocate. She was early destined for the church, and assumed the dress of a novice in 1599. By concealing her age from the Pope, her father obtained a bull nominating her abbess of Port-Royal when she was little more than eleven years old. For some time after entering on office she spent a purely secular life, performing the needful religious exercises, but taking little or no interest in them, and gradually acquiring an intense dislike to the profession she had adopted. At last, in 1608, a sermon preached in the convent chapel produced a great change in her mind. She now saw that her true duty and happiness lay in the work of the convent; she inflicted on herself severe penances, persuaded the nuns to adhere rigorously to their vow of poverty, and excluded even her own relatives from the cloister precincts. The fame of the reformation wrought by her earnestness spread abroad, and when Mme. d'Estrées, abbess of Maubuisson, was, on account of her gross misconduct, removed and sent into confinement among the *Filles Penitentes* at Paris, Angélique was appointed to take charge of the convent. From this she was forcibly ejected by Mme. d'Estrées, and had to be reinstated by a body of the royal archers. For five years she laboured in Maubuisson, and wrought a considerable change in the state of the convent. In 1623 she returned to Port-Royal, and three years later, as their accommodation became too limited for their numbers, the community removed to the house known as Port-Royal de Paris. Here Angélique accomplished what she had long desired; she was allowed to resign her dignity as abbess, the office was made triennial, and the occupants of it were elected by the nuns. From 1633 to 1636 she acted as superior of a religious community newly instituted in Paris, and then returned, as prioress, to Port-Royal, where her sister Agnes had been elected abbess. In 1648 she, with a few companions, went back to Port Royal des Champs, and there had opportunities for showing much kindness to the poor, who were oppressed by the disastrous civil wars. Angélique died in 1661, just before the great storm of persecution broke over Port-Royal. Materials for her life are to be found in the general histories of Port-Royal, and in the works of the younger Angélique. A very full memoir of her is given in Miss Frances Martin's work, *Angélique Arnauld*, Macmillan, 1873.

ARNDT, Ernst Moritz, a distinguished German patriot, poet, and historical and miscellaneous writer, was a native of the island of Rügen in the Baltic, which at the time of his birth belonged to Sweden. He was born at Schoritz on the 26th December 1769. The second of a family of eight, he inherited from his father the sound mind in the sound body, good sense, practical sagacity, warm feeling, and a strong will; and from his mother the earnest, devout, and Christian spirit which animated all his words and deeds. After passing his boyhood in his father's house, familiar with the solitudes of sea and wood, trained in habits of accurate observation and cheerful activity, and stimulated by books to literary attempts of his own, he was sent, in 1787, to the gymnasium of Stralsund. There he studied for two years, and, after spending the next two years in the old home, he entered, in the spring of 1791, the university of Greifswald, whence he removed to Jena. There he fell under the influence of Fichte, whose teachings he received with eager love, and whose memory remained ever dear to him. Destined for the church, he applied himself at first to the study of theology, but after some years, conscious of no inward call, he renounced that pursuit. In 1796 he became a private tutor at Altenkirchen; visited afterwards Austria, Hungary, Italy, and France, giving to the world the fruits of his observation in a series of remarkable volumes published in the course of the following years; and in 1800 settled at Greifswald as "privat-docent" of history and philology. In 1806 he was named professor extraordinary. His special faculty and vocation distinctly revealed themselves in his bold *History of Serfdom in Pomerania and Rügen* (1803), for which he was denounced by the nobles to the king of Sweden. So convincing was the book that, in 1806, serfdom was abolished. In his next work, *Geist der Zeit* (1807), he aimed at a higher mark. He flung down the gauntlet to Napoleon I. who, in the campaigns of Austerlitz and Jena, had laid Germany prostrate before him, and in burning words he called on his countrymen to rise and shake off the hateful yoke. So great was the excitement produced by this appeal that Arndt, to escape the vengeance of Napoleon, took refuge in Sweden. The work passed through fifteen editions, and grew into four volumes, to which a fifth part, entitled *Pro Populo Germanico*, was added in 1854. Arndt having thus erected the banner of German freedom and unity, devoted himself thenceforth with unflagging courage to the great cause. In pamphlets, poems, and songs he communicated his own enthusiasm to his countrymen; and he zealously co-operated with Stein in the reorganisation of the army and preparation for the final struggle. The War of Liberation followed, and Germany was free. Long years were, however, to pass before unity was attained. One of the most famous of Arndt's songs was that commencing, "*Was ist der Deutschen Vaterland.*" After the peace he returned to Germany, edited at Cologne a political journal, entitled *Der Wächter* (1815–16), and in 1818 was appointed to the chair of history at Bonn. But his bold demands for constitutional reform offended the Diet, and being deprived in the following year, he passed twenty years in retirement and literary activity. In 1840 he was reinstated in his professorship, and in 1841 he was chosen rector of the university. The revolutionary outbreak of 1848 rekindled in the venerable patriot his old hopes and energies, and he took his seat as one of the deputies to the National Assembly at Frankfort. Seeing no prospect of a satisfactory issue he retired with the adherents of Von Gagern. With rare freshness and vigour he continued to lecture and to write, and on his 90th birthday received from all parts of Germany good wishes and love-tokens. About a month later, January 29, 1860, he made a peaceful departure out of the world. Arndt was twice married, first in 1800, but his wife died in the following year in giving birth to a son; he married a second time in 1817. Among his numerous works, in addition to those already named, are—*Nebenstunden, eine Beschreibung und Geschichte der Schottländischen Inseln und der Orkaden* (1820); *Die Frage über die Niederlande* (1831); *Erinnerungen aus dem äussern Leben* (1843); *Wanderungen und Wandlungen mit dem Reichsfreiherrn H. K. F. von Stein* (1858); and a complete edition of his *Gedichte* (1860). Lives of Arndt have been written by W. Neumann and Wilhelm Baur; and statues have been erected to his memory at Schoritz, his birth-place, and at Bonn, where he lies buried. (W. L. R. C.)

ARNDT, John, was a famous Protestant theologian of the 16th century, and may be regarded as the founder of the German Pietism of a later generation. He was born at Ballenstädt, in Anhalt, in 1555, and studied in a variety of universities—in Helmstädt in 1576; in Wittenberg in 1577, when the crypto-Calvinist controversy was at its height, and where he took the side of Melanchthon and the crypto-Calvinists; in Strasburg, under Pappus, who was a strict Lutheran and had a great influence over him; in Basel, where he studied theology under Sulcer, and also medicine. In 1581 he went back to Ballenstädt, but was soon recalled to active life by his appointment to the pastorate at Badeborn in 1583. After some time his Lutheran tendencies exposed him to the anger of the authorities, who were of the Reformed church. He found an asylum in Quedlinburg, and afterwards was transferred to St Martin's church in Brunswick. Arndt's fame rests on his writings, which were mainly of a mystical devotional kind, and were inspired by Bernard, Tauler, and Thomas à Kempis. His principal work is *The True Christianity*, which has been translated into most European languages, and has served as the foundation of many devotional works, both Roman Catholic and. Protestant. In this book Arndt dwells upon the mystical union between the believer and Christ, and his aim is to correct the purely forensic side of the Reformation theology, which paid almost exclusive attention to Christ's death *for* His people, by drawing attention to Christ's life *in* His people. Like Luther, Arndt was very fond of the little anonymous book, *Deutsche Theologie*, and published an edition with a preface recommending it. The first edition of his *True Christianity* appeared in 1605. His other works are *The Death of Adam and the Life of Christ*, *Thoughts on various Books of the Bible*, *The House and the Heart Church*, *Soul Medicine for the Pestilence*, and *De Unione Credentium cum Christo*. His *True Christianity* has been translated into English at least twice, and has gone through a great number of editions; the best known translation is that of A. W. Boehm, Lond. 1720. Several of his sermons are published in R. Nesselmann's *Buch der Predigten*, 1858. Arndt has always been held in very high repute by the German Pietists, and the founders of Pietism, Spener and Storr, repeatedly call attention to him and his writings; they have gone so far as to compare him to Plato, *cf.* C. Scheele, *Plato und Johan Arndt, Ein Vortrag, &c.*, 1857. A valuable account of Arndt is to be found in C. Aschmann's *Essai sur la Vie, etc., de J. Arndt.* (T. M. L.)

ARNE, Thomas Augustine, musical composer, was born in London on the 28th May 1710, his father being an upholsterer. Intended for the legal profession, he was educated at Eton, and afterwards apprenticed to an attorney. His natural inclination for music, however, proved irresistible, and his father, finding from his performance at an amateur musical party that he was already a skilful violinist, furnished him with the means of educating himself in his favourite art. In 1733 he produced his first work,—a setting of Addison's *Rosamond*, the heroine's part being intended for his sister, who afterwards became celebrated as Mrs Cibber. This proving a success was immediately followed by a burletta, entitled *The Opera of Operas*, based on Fielding's *Tom Thumb*. His individuality of style first distinctly asserted itself in the music to Milton's *Comus*, which was performed at Drury Lane in 1738, and speedily established his reputation. In 1740 he wrote the music for Thomson and Mallet's *Masque of Alfred*, which is noteworthy as containing the most popular of all his airs—*Rule Britannia*. In the same year he married Cecilia Young, who was considered the finest English singer of the day. Along with his wife he went, in 1742, to Ireland, where he remained two years. On his return to London he was engaged as leader of the band at Drury Lane Theatre (1744), and as composer at Vauxhall (1745). In 1759 he received the degree of Doctor of Music from Oxford. Three years later he produced, at Covent Garden, his opera of *Artaxerxes*, the popularity of which is attested by the fact that it continued to be performed at intervals for upwards of eighty years. The libretto was a translation by Arne himself, very poorly executed, of Metastasio's *Artaserse*. In addition to his numerous operas, Arne wrote several oratorios, which made little impression at the time, and are now almost entirely forgotten. His success in this department might have been greater but for the contemporary existence of the transcendent genius of Handel, though his deficiency in grandeur of conception and scientific resource is enough of itself to account for his failure. He is, however, undoubtedly entitled to a place in the first rank of native English composers. Though inferior to Purcell in intensity of feeling, he has not been surpassed by any of the school as a composer of graceful and attractive melody. There is something akin to genius in such airs as *Rule Britannia* and *Where the bee sucks*, which still retain their original freshness and popularity. As a writer of glees he does not take such high rank, though he deserves notice as the leader in the revival of that peculiarly English form of composition. Dr Arne died on the 5th March 1778.

ARNHEM, or Arnheim (according to some the *Arenacum* of the Romans, Arnoldi Villa in the Middle Ages), the chief town in the province of Guelderland, in the Netherlands, on the right bank of the Rhine along the slope of the Veluwe Hills. It is a clean and prosperous place, in a pleasant and beautiful district, and is much frequented by the wealthy merchants of the Low Countries, whose villas and gardens adorn its environs. The *Groote Kerk*, or principal church, formerly dedicated to St Martin, and now to St Eusebius, contains, besides other objects of interest, the marble monument of Charles of Egmont. The *Stadhuis*, or town-house, by Maarten van Rossum, is remarkable for the grotesque ornamentation which has earned it the name of the *Duivelshuis*. There are also a government-house, a court-house, a gymnasium, an orphanage, a hospital for invalided soldiers (Bronbeek's), a large assembly-hall (*Musis Sacrum*), a library, a theatre, barracks, and a good number of churches and schools. The town, formerly connected with the Hanseatic League, has still a considerable traffic by river and canal and rail, manufactures tobacco, which is largely cultivated in the neighbourhood, woollen and cotton goods, paper, earthenware, soap, &c., carries on wool-combing and dyeing, and has oil and bark mills. Arnhem was fortified in 1233 by Otho III., duke of Guelders. In 1505 it received the right of coining from Philip of Spain, duke of Burgundy. In 1514 Charles of Egmont took it from the Burgundians. In 1543 Charles V. made it the seat of the Council of Guelders. The States-General got possession of it in 1585, and it resisted all the attacks of the Spaniards. In 1586 Sir Philip Sydney died there from the effects of his wound. The French took the town in 1672, but left it dismantled in 1674. It was refortified by Coehoorn in the beginning of the 18th century. In 1795 it was again stormed by the French, and in 1813 it was taken from them by the Prussians under Bülow.

ARNICA. A genus of plants belonging to the natural order *Compositæ* (composite family). The flowers are clustered in heads (*capitula*), and are surrounded by an involucre composed of two rows of small leaflets called bracts. The outer flowers of the head are strap-shaped (ligulate), and contain pistils only, while the inner or central florets are tubular and have both stamens and pistils. The style is hairy, and the fruit is cylindrical, tapering at each end, and bears at its summit a pappus, consisting of rigid hairs in a single row. The most important species is *Arnica montana* (mountain tobacco), a perennial plant found in meadows throughout the northern and central regions of the northern hemisphere, but not extending to Britain. It grows on the mountains of Western and Central Europe. A variety of it, with very narrow leaves, is met with in Arctic Asia and America. The heads of flowers are large, orange yellow, and borne on the summit of the stem or branches. The outer ligulate flowers are an inch in length. The achenes (fruits) are brown and hairy. The root, or rather the root-stock, has been used in Pharmacy. It is contorted and of a dark brown colour, an inch or two in length. It gives off numerous simple roots from its under side, and shows on its upper side the remains of rosettes of leaves. It yields an essential oil in small quantity, and a resinous matter called arnicin. Arnica has been used as a stimulant in low fevers, and also in cases of palsy. It is said also to act in promoting perspiration. It is a popular remedy for chilblains, and it is said to prevent the blackness of bruises, The flowers have also been used in the form of tincture. They have an unpleasant odour. The plant is not much used at the present day. (J. H. B.)

ARNIM, BETTINA VON, famous for her acquaintance and correspondence with Goethe, was a member of the Brentano family, and born at Frankfort, April 4, 1785. Her acquaintance with Goethe continued from 1807 until 1811, when it was brought to a close by her offensive behaviour to his wife. Shortly after his death she published an extensive correspondence alleged to have passed between the parties. Its genuineness was immediately contested by Goethe's old friend Riemer, and the discussion leaves no doubt that it is everywhere interpolated, and to a great extent wholly fictitious. Bettina never could produce the originals of the letters; and it has been demonstrated that the sonnets which she claimed as addressed to herself, and as partly versifications of her own ideas, were in fact addressed to Minna Herzlieb before Goethe had even seen Bettina. This discovery effectually relieves the poet's memory from some very unpleasant imputations. The literary merits of the work are in some respects very considerable. Nothing can surpass Bettina's liveliness, freshness, originality, and graphic power when dealing with actual persons and things: she is, unfortunately, addicted to abstract speculation, and then becomes unintelligible. Though probably equally supposititious, her correspondence with the friend of her youth, the interesting and unfortunate Caroline von Günderode, is superior to her more celebrated work from its greater truth to nature; and her almost unknown volume of professed letters to and from her brother, Clemens Brentano, is the best of all. These later productions failed to attract a public sated with her peculiar mannerism, and Bettina had sunk into comparative obscurity before her death in 1859. Bettina was a true member of a family whose folly was in her time proverbially said to begin where the folly of others ceases. Her vanity, caprice, mendacity, and utter want of principle can only be excused on the supposition of her virtual irresponsibility for her actions. She possessed a brilliant fancy, and her remarks occasionally display great penetration; her conversational powers are described as marvellous. One of her freaks was to translate her correspondence with Goethe into English; the result is an unparalleled literary curiosity. The evidence respecting this correspondence is ably summed up in Mr Lewes's *Life of Goethe*. (R. G.)

ARNIM, or ARNHEIM, JOHAN GEORG BARON VON, one of the most distinguished men during the period of the Thirty Years' War, both as a general and as a diplomatist, was born in 1586, at Boitzenburg, in the province of Brandenburg. He entered the Swedish army, and served under Gustavus Adolphus. In 1626 he, though a Protestant, was induced by Wallenstein to join the imperial army. He gained great distinction by his military and diplomatic talents, and became the close friend and faithful ally of Wallenstein. After the dismissal of the latter from his command in 1630, Arnim went over to the elector of Saxony, and, at the battle of Leipsic, led the left wing of the united Saxon and Swedish armies. But he disliked the Swedes, who distrusted him; and it was mainly by his influence that the elector detached his forces from Gustavus Adolphus, and that at the peace of Prague the Saxons seceded from their alliance with Sweden. In 1632 Wallenstein, who had been restored to his command, took the field against his old comrade, but little was done by either, and more than a suspicion was roused that they were playing into each other's hands. In February 1634 Wallenstein was assassinated, and Arnim at once began more active operations. In May he gained a great victory over the imperialists at Liegnitz; but after the conclusion of peace, not thinking himself sufficiently honoured by the elector, he withdrew to his castle of Boitzenburg. Here he was seized by the Swedes, and imprisoned at Stockholm. He escaped, and was engaged in raising an army to revenge himself when he died suddenly in 1641.

ARNIM, KARL OTTO LUDWIG VON, a German writer of travels, was born at Berlin in 1779, travelled from 1835 to 1844 through Turkey and Greece, France, Spain, and Italy, and died in 1861. He was attached for some time to the German embassy at London, and wrote in English *Napoleon's Conduct towards Prussia* (1814), and *German National Melodies* (1816). He also translated some English plays and poems. His reputation rests mainly on his *Flüchtige Bemerkungen eines flüchtig Reisenden* (1838–1850), which are highly praised for their lively and graceful style.

ARNIM, LUDWIG ACHIM VON, a distinguished German poet and novelist, was born at Berlin in 1781. He studied at Vienna and Göttingen, and took the degree of M.D., though he never practised as a physician. His attention, however, in his early years seems to have been specially directed towards the natural sciences, and his first literary performance (*Theorie der Elektrischen Erscheinungen*) was in that department. But even in this essay he showed the fondness for the supernatural and the predilection for romance that appeared so strongly in his next work, *Ariel's Offenbarungen*, 1804. In the same year he published *Hallin's Liebesleben*, with an appendix containing a biography of Rousseau. He spent some years in travelling through parts of Germany and collecting old popular legends and songs. A selection of these he published at Heidelberg in conjunction with the poet Clemens Brentano, whose sister Bettina (noticed above) he afterwards married. The volumes, entitled *Des Knaben Wunderhorn*, were received with great favour. In 1809 he published the *Wintergarten*, a collection of tales; in 1810 an admirable novel, *Die Gräfin Dolores;* in 1811 a humorous dramatic romance, *Halle und Jerusalem*, and a novel, *Isabelle von Ægypten;* and two years later his *Schaubühne* or dramatic pieces. His literary activity was for some time interrupted by the war in Germany, but in 1817 he published his last great romance, *Die Kronenwächter*, the scene of which is laid in the time of the Emperor Maximilian. Arnim died in 1831. His works have been published in a collected form at Berlin, 1839–1846. They manifest great originality of invention, but are for the most part marred by the utter absence of literary form, being vague, incoherent, and whimsical to the last degree. Arnim is the subject of a brilliant but much too favourable criticism in Heine's *De l'Allemagne*.

ARNISÆUS, HENNINGUS, a German physician, was born at Halberstadt, probably about 1580. After completing his studies at the university of Helmstädt and taking his degree as doctor of medicine, he seems to have lectured for some time on moral philosophy at Frankfurt-on-the-Oder. In 1613 he was appointed one of the professors of medicine at Helmstädt, and he is said to have constructed there a chemical laboratory and a botanical garden. His anatomical plates were very celebrated, and some of them were extant in the time of Haller. In 1620 he was made court physician to Christian IV. of Denmark, and removed to Copenhagen, where he died in 1638. The greater number of his extant works are on the theory of politics, such as *Doctrina Politica*, published after his death, *De Republica*, *De jure Majestatis*, &c.; the following medical tracts are ascribed to him, *Disquisitiones de partus humani legitimis terminis* and *Disputatio de lue venerea*.

ARNO (the ancient ARNUS), a celebrated river of Italy. It rises in Monte Falterona, in the Apennines, descends into the valley of Casentino, in Upper Tuscany, passes the town of Bibbiena into the plain of Arezzo, where it receives the Chiana as a tributary, and enters the narrow valley of Laterina. Thence it issues through the rocky defile Dell' Inferno, pours into the lovely Val d'Arno, sweeps beneath the woods of Vallombrosa, and, after receiving the Sieve, enters the plain of Florence and flows through that city. Ten miles below Florence it is confined in an artificial channel, formed by the ancient Etruscans, for the purpose of draining the plain. It receives several tributaries, and enters the plain of Pisa, which it traverses; and after a further course of eight miles, falls into the Tuscan sea by an artificial embouchure excavated in 1603. Its whole winding course is about 140 miles. At Florence it is 400 feet wide, but is fordable in summer. It is liable to sudden floods, and then is impetuous, carrying down with it immense quantities of earth and stones, by which its bed is elevated; in many places it requires frequent embankment. The most remarkable inundations are those of 1537 and 1740, the water on the former occasion rising 8 feet in the city of Florence. On the banks of the upper Arno are vast accumulations of fossil bones of the elephant, rhinoceros, hippopotamus, and bear, especially between Arezzo and Florence.

ARNO, or AQUILA, tenth bishop and first archbishop of Salzburg, was one of those learned churchmen whom Charles the Great gathered round him, and who did so much to frame and strengthen that alliance between the Emperor and the Pope which lay at the basis of the Holy Roman empire of the West. The occasion of his introduction to the emperor was the defeat of Thassilo, duke of Bavaria, who had made war upon Charles, and was compelled to sue for peace. He sent at the head of the embassy Arno, who was then bishop of Salzburg, and in whose talents and fidelity he had the utmost confidence. The embassy did not succeed, mainly because Thassilo refused to make the required concessions, and Bavaria was annexed to the empire. When this took place Charles secured the services of Arno, and got for him from the Pope the archbishopric of Salzburg in 798 A.D. From this time forward Arno was frequently at the court of Charles, and became the intimate associate of Alcuin and other scholars whom the emperor delighted to gather around him. In 799 he presided at a synod of the church held at Reisbach, and in 807 at the more important synod of Salzburg. The zeal which he evinced for the conversion of the pagans of Hungary and Bohemia commended him to his ecclesiastical superiors. He established a library in Salzburg formed on the model of the emperor's palace library, and did all he could to further the interests of learning within his diocese. Assisted by a deacon named Benedict, he published a catalogue of the church lands, proprietary rights, and so on, belonging to the church in Bavaria. This is of great value to the historical student, and goes by the name of the *Congestum*, or *Indiculus Arnonis*; an edition with notes was published by Frederick Keinz, Munich, 1869. Arno also wrote *De Donis Ducum Bavariæ Salzbrugensi Ecclesiæ datis*, which is to be found in the *Thesaurus Monumentorum ecclesiasticorum et historicorum* (Antwerp, 1725). (T. M. L.)

ARNOBIUS, called Afer, and sometimes the Elder, was a native of Sicca Venerea in Numidia. The date of his birth is uncertain, but it must have been during the latter part of the 3d century of our era. He was a teacher of rhetoric, and at first an opponent of Christianity. His conversion is said by Jerome to have been occasioned by a dream; and the same writer adds that the bishop to whom Arnobius applied distrusted his professions, and asked some proof of them, and that the treatise *Adversus Gentes* was composed for this purpose. But this story seems rather improbable; for Arnobius speaks contemptuously of dreams, and besides, his work bears no traces of having been written in a short time, or of having been revised by a Christian bishop. From internal evidence the time of composition may be fixed at about 303 A.D. Nothing further is known of the life of Arnobius. He is said to have been the author of a work on rhetoric, which, however, has not come down to us. His great treatise, in seven books, *Adversus Gentes* (or *Nationes*), on account of which he takes rank as a Christian apologist, appears to have been occasioned by a desire to answer the complaint then brought against the Christians, that the prevalent calamities and disasters were due to their impiety, and had come upon men since the establishment of their religion. In the first book Arnobius carefully discusses this complaint; he shows that the allegation of greater calamities having come upon men since the Christian era is false; and that, even if it were true, it could by no means be attributed to the Christians. He skilfully contends that Christians who worship the self-existent God cannot justly be called less religious than those who worship subordinate deities, and concludes by vindicating the divinity of Christ. The second book is principally taken up with a discussion on the soul, which Arnobius does not think is of divine origin, and which he scarcely believes to be immortal. Curiously enough, he is of opinion that a belief in the soul's immortality would tend to remove moral restraint, and have a prejudicial effect on human life. In the concluding chapters he answers the objections drawn from the recent origin of Christianity. Books iii., iv., and v. contain an examination of the heathen mythology, in which he narrates, with powerful sarcasm, the scandalous chronicles of the gods, and contrasts with their grossness and immorality the pure and holy worship of the Christian. These books are valuable as a repertory of mythological stories. Books vi. and vii. discuss, in a very admirable manner, the questions of sacrifices and worship of images. He points out the absurdities of the heathen practices in these respects, and shows how unnecessary they are in a pure system of religion. The work of Arnobius appears to have been written when he was a recent convert, for he does not possess a very extensive knowledge of Scripture. He knows nothing of the Old Testament, and only the life of Christ in the New, while he does not quote directly from the Gospels. He is also at fault in regard to the Jewish sects. The best editions of his work are those of Orelli, 1816; Hildebrand, 1844; and Oehler, 1846. It has been translated into English as vol. xix. of the *Ante-Nicene Christian Library* (1871).

ARNOBIUS, the younger, a Christian priest or bishop in Gaul, flourished about 460 A.D. He is the author of a mystical and allegorical commentary on the Psalms, first published by Erasmus in 1522, and by him attributed to the elder Arnobius. It has been frequently reprinted, and in the edition of De la Barre, 1580, is accompanied by some notes on the Gospels by the same author. To him has sometimes been ascribed the anti-Augustinian treatise *Prædestinatus*, which is anonymous. His opinions, as appears from the commentary, are semi-Pelagian.

ARNOLD OF BRESCIA, remarkable as a forerunner of the Reformation and assailant of the Pope's temporal power, was born about the beginning of the 12th century, and became a priest in his native city. The fame of Abelard's eloquence induced him to repair to France for the sake of becoming his disciple. On his return he bitterly attacked the temporal dominion of the Pope and the wealth of the clergy, advocating the secularisation of all ecclesiastical property. He is said to have also impugned the current doctrine of the sacraments, but this appears to have been an invention of his adversaries. Persecuted in Italy, he returned (1140) to Abelard, and incurred the enmity of the latter's great antagonist, St Bernard, whose denunciations drove him to seek refuge at Zurich, where he acquired great influence. A popular insurrection at Rome (1146) encouraged him to proceed to that city, where he appeared as a political agitator, preaching the deposition of the Pope and the restoration of the ancient republic. He became exceedingly popular, and aided in expelling the Pope from the city, but no practical effect appears to have been given to his plans. The Romans obtained, however, a free constitution on a different model. Upon their demanding the confirmation of this at the accession of the new Pope, Adrian IV. (the Englishman, Nicholas Breakspear), it was refused unless upon condition of their delivering up Arnold. The demand being indignantly rejected, the city, for the first time in history, was laid under an interdict. The consequent suspension of all religious services so powerfully affected the people as to occasion a tumult, which compelled Arnold to take refuge in a castle in Campania (1155). A new emperor, Frederick Barbarossa, had meanwhile been elected, and was on the way to his coronation in Rome. By him Arnold was arrested and delivered up to the Pope, and the Roman constitution suppressed. Arnold was hanged, his body burned, and the ashes thrown into the Tiber. In history he ranks with Rienzi and Savonarola. His enemies have been his biographers, and they are unanimous in acknowledging his eloquence, his personal influence, and his perfect disinterestedness. Allowing for a romantic attachment to antiquated political forms, he was as a politician greatly in advance of his age. The best proof of his truly prophetic insight into the needs of his country is that, although he left no writings and no disciples, his name is to this day a popular cry in Italy. It is also the subject of, perhaps, the only truly national Italian drama, a tragedy by Niccolini. (Franke, *Arnold von Brescia*; Guibal, *Arnaud de Brescia et les Hohenstauffen;* Gregorovius, *Rom im Mittelalter*, vol. iv.) (R. G.)

ARNOLD, Samuel, a distinguished English composer, was born at London in 1740. He received a thorough musical education at the Chapel Royal under Dr Nares, and when little more than twenty years of age was appointed composer at Covent Garden Theatre. Here, in 1765, he produced his popular opera, *The Maid of the Mill.* In 1776 he transferred his services to the Haymarket Theatre. In 1783 he was made composer to George III., and, ten years later, organist in Westminster Abbey, where, on his death in 1802, he was interred. His operas were very numerous and popular, but they have not lived. The best of them were *The Maid of the Mill, Rosamond, Inkle and Yarico, The Battle of Hexham, The Mountaineers.* He also wrote several oratorios, which have shared the fate of his operas. The first of them was *The Cure of Saul*, in 1767, which was very successful. The others are *Abimelech, The Resurrection,* and *The Prodigal Son.* In 1786 he began an edition of Handel's works, which extended to 40 volumes, but was never completed. It is considered extremely inaccurate. He also published a continuation, in 4 volumes, of Dr Boyce's Cathedral Music.

ARNOLD, Thomas, a clergyman of the Church of England, was born at West Cowes, in the Isle of Wight, on the 13th of June 1795. He was the son of William and Martha Arnold, the former of whom occupied the situation of collector of customs at Cowes. Deprived at an early age of his father, who died suddenly of spasm in the heart in 1801, his initiatory education was confided by his mother to her sister, Miss Delafield, who, with affectionate fidelity, discharged the office with which she had been intrusted. From her tuition he passed to that of Dr Griffiths, at Warminster, in Wiltshire, in 1803; and in 1807 he was removed to Winchester, where he remained until 1811, having entered as a commoner, and afterwards become a scholar of the college. In after life he retained a lively feeling of interest in Winchester School, and remembered with admiration and profit the regulative tact of Dr Goddard, and the preceptorial ability of Dr Gabell, who were successively headmasters during his stay there.

From Winchester he removed to Oxford in 1811, where he became a scholar at Corpus Christi College; in 1815 he was elected Fellow of Oriel College; and there he continued to reside till 1819. This interval was diligently devoted to the pursuit of classical and historical studies, to preparing himself for ordination, and to searching investigations, under the stimulus of continual discussion with a band of talented and congenial associates, of some of the profoundest questions in theology, ecclesiastical polity, and social philosophy. The authors he most carefully studied at this period were Thucydides and Aristotle, and for their writings he formed an attachment which remained to the close of his life, and exerted a powerful influence upon his mode of thought and opinions, as well as upon his literary occupations in subsequent years. Herodotus also came in for a considerable share of his regard, but more, apparently, as a book of recreation than one for work. In theology, his mind, accustomed freely and fearlessly to investigate whatever came before it, and swayed by an almost scrupulous dread of aught that might appear to savour of insincerity, was doomed to long and anxious hesitation upon several points of fundamental importance before arriving at a serene and settled acceptance of the great verities of Christianity. Once satisfied, however, of these, his faith remained clear and firm; and having received his religion, not by tradition from men, but as the result of an earnest, penetrating, and honest examination of the evidence on which it rests, he not only held it with a steadfast grasp, but realised it, and felt it as a living and guiding power. From this time forward his life became supremely that of a *religious* man. To the name of Christ he was prepared to "surrender his whole soul," and to render before it "obedience, reverence without measure, intense humility, most unreserved adoration" (*Sermons*, vol. iv. p. 210). He did not often talk about religion; he had no inclination to gossip about his experience, or dwell upon the frames and feelings through which he passed; he had not much of the accredited phraseology of piety even when he discoursed on spiritual topics; but no man could observe him for any length of time without feeling persuaded that more than most men he was directed by religious principle and feeling in all his conduct. The fountain of his piety was in his heart's core; and its streams mingled easily with all the issues of his life. As his biographer has beautifully remarked, "his natural faculties were not unclothed, but clothed upon; they were at once coloured by, and gave a colour to, the belief which they received."

He left Oxford in 1819 and settled at Laleham, near Staines, where he was occupied chiefly in superintending the studies of seven or eight young men who were preparing for the university. His spare time was devoted to the prosecution of studies in philology and history, more particularly to the study of Thucydides, and of the new light which had been cast upon Roman history and upon historical method in general by the researches of Niebuhr. He was also occasionally engaged in preaching, and it was whilst here that he published the first volume of his sermons. Shortly after he settled at Laleham, he entered into the marriage relation with Mary, youngest daughter of the Rev. John Penrose, rector of Fledborough, Nottinghamshire.

After nine years spent at Laleham, he was induced to offer himself as a candidate for the head-mastership of Rugby, which had become vacant; and though he entered somewhat late upon the contest, and though none of the electors were personally known to him, he was nevertheless successful. He was elected in December 1827; in June 1828 he received priest's orders; in April and November of the same year he took his degrees of B.D. and D.D., and in August entered on his new office.

In one of the testimonials which accompanied his application to the trustees of Rugby, the writer stated it as his conviction, that "if Mr Arnold were elected, he would change the face of education all through the public schools of England." Nobly was the somewhat hazardous pledge redeemed by him in whose name it had been given. Under his superintendence the school became not merely a place where a certain amount of classical or general learning was to be obtained, but a sphere of intellectual, moral, and religious discipline, where healthy characters were formed, and men were trained for the duties, and struggles, and responsibilities of life.

Rugby was privileged to enjoy his superintendence for nearly fourteen years. During this period his energies were chiefly devoted to the business of the school; but he found time also for much literary work, as well as for an extensive correspondence. Five volumes of sermons, an edition of Thucydides, with English notes and dissertations, a History of Rome in three vols. 8vo, besides numerous articles in reviews, journals, newspapers, and encyclopædias, are extant to attest the untiring activity of his mind, and his patient diligence during this period. His interest also in public matters was incessant, especially ecclesiastical questions, and such as bore upon the social welfare and moral improvement of the masses.

In 1841 Dr Arnold received from Lord Melbourne, then prime minister, the offer of the chair of modern history at Oxford, an offer which he accepted with peculiar satisfaction. On the duties of this new office he entered on 2d December 1841, by delivering his inaugural lecture, amidst circumstances which he felt to be peculiarly gratifying and flattering. Seven other lectures were delivered during the first three weeks of the Lent term of 1842; the whole have been published since his death.

A few months after the delivery of his lectures, Arnold was suddenly removed from his earthly duties and anticipated enjoyments by an attack of angina pectoris. The midsummer vacation had arrived, and he was preparing to set out with his family to Fox How, a favourite retreat, where he had purchased some property and built a house, in Westmoreland. After a busy day spent in various duties, he retired to rest apparently in perfect health. Between five and six next morning he awoke in severe pain. All attempts to arrest the fatal malady proved fruitless. He bore with heroic fortitude and Christian resignation his sufferings, until eight o'clock, when he expired. The day on which he died was Sunday, the 12th of June 1842. His remains were interred on the following Friday in the chancel of Rugby chapel, immediately under the communion table.

We have no space left to attempt a delineation of the separate features of Arnold's character. We can only remark in general, that the great peculiarity and charm of his nature seemed to lie in the regal supremacy of the moral and the spiritual element over his whole being and powers. His intellectual faculties were not such as to surpass those of many who were his contemporaries; in scholarship he occupied a subordinate place to several who filled situations like his; and he had not much of what is usually called tact in his dealings either with the juvenile or the adult mind. What gave him his power, and secured for him so deeply the respect and veneration of his pupils and acquaintances, was the intensely religious character of his whole life. He seemed ever to act from a severe and lofty estimate of duty. To be just, honest, and truthful, he ever held to be the first aim of his being. With all this, there was intense sympathy with his fellows, the tenderest domestic affections, the most generous friendship, the most expansive benevolence. But to understand aright his claims upon our respect and homage, the history of his life must be read at large. As has been truly observed by one who seems to have known him well—"His Thucydides, his history, his sermons, his miscellaneous writings, are all proofs of his ability and goodness. Yet the story of his life is worth them all."—*Edin. Rev.*, vol. lxxxi. p. 234. His life has been most ably written by the Rev. A. P. Stanley, M.A., now D.D. and Dean of Westminster, in two volumes, 8vo. Lond. 1845. (W. L. A.)

ARNOTT, NEIL, M.D., F.R.S., a distinguished physician and physicist, was born at Arbroath, 15th May 1788. His parents, who were Roman Catholics, removed to Blairs, near Aberdeen, when Arnott was eight years old, and three years afterwards took up their abode in Aberdeen, which enabled him to attend the grammar school there. In 1801 he entered Marischal college, where he took special interest in the natural philosophy subjects, taught at that time by Professor Copland, a skilful experimenter. There his natural bent to physical science was greatly strengthened. He studied medicine first at Aberdeen, and subsequently under Sir Everard Home, through whom he obtained, while yet in his nineteenth year, the appointment of full surgeon to an East Indiaman. After making two voyages to China he settled in 1811 to practise in London, and speedily acquired high reputation in his profession. Within a few years he was made physician to the French and Spanish embassies. In 1836 he was appointed a member of the Senate of the new university of London, and became a fellow of the Royal and Geological Societies. In 1837 he was made a physician extraordinary to the Queen. From his earliest youth Arnott had an intense love of natural philosophy, constantly using illustrations and applications of its principles. To this liking was added an inventiveness which served him in good stead in his profession, and to which we owe the "Arnott water-bed," the "Arnott ventilator," the "Arnott stove," &c., all of which, with characteristic philanthropy, he refrained from patenting. He was the author of several works bearing on physical science or its applications. The most important of these is his *Elements of Physics*, published in 1827, the most successful attempt that had ever been made to popularise a scientific subject. It went through six editions in his lifetime. In 1838 he published a treatise on *Warming and Ventilating*, and, in 1855, one on the *Smokeless Fireplace*. He took a lead in sanitary improvements generally. The chief characteristic of his writings and inventions is their high practical utility. He was a strong advocate of scientific, as opposed to purely classical, education; and he manifested his interest in natural philosophy by the munificent gift of £2000 to each of the four universities of Scotland and to the university of London, to promote its study in the experimental and practical form. He died in London, 2d March 1874.

ARNOTTO, or ANNATTO, is a dyeing material produced from the seeds of *Bixa Orellana* (Nat. Ord. *Flacourtiaceæ*), a small tree which grows in Central and South America. The seeds are surrounded with a thin coating of a waxy pulp, which is separated from them by washing in water, passing the liquid through a sieve, and allowing the suspended pulp to deposit. The water is then drained away and the paste dried, till it is a thick, stiff, unctuous mass. In this state it has a dark orange-red colour, and is known as "roll" or "flag" arnotto, according to the form in which it is put up, but when further dried it is called "cake" arnotto. Arnotto is much used by South American Indians for painting their bodies; among civilised communities its principal use is for colouring butter, cheese, and varnishes. It yields a fugitive bright orange colour, and is to some extent used alone, or in conjunction with other dyes, in the dyeing of silks and in calico printing.

ARNSBERG, a city of Westphalia, in Prussia, the chief town of a government and circle of the same name, 51° 24′ N. lat., 8° 7′ E. long. It is situated on an eminence almost surrounded by the River Ruhr, 44 miles S.E. of Munster, and 58 miles E.N.E. of Dusseldorf. It is the seat of the provincial authorities, and has a court of appeal, a Catholic gymnasium, which was formerly the Benedictine abbey of Weddinghausen, a library, a normal seminary, and a society of agriculture. Weaving, brewing, and distilling are carried on, and there are manufactories of white lead, shot, and paper, as well as works for the production of railway plant. Arnsberg was the capital of the ancient duchy of Westphalia (incorporated with Hesse Darmstadt in 1803, and with Prussia in 1816), and was a member of the Hanseatic league. The new part of the town has been built since 1815. Population in 1873, 5123. Near the town are the ruins of an ancient castle once the residence of the earls of Arnsberg, the last of whom, Gottfried, sold his earldom in 1368 to the archbishop of Cologne.

ARNSTADT, an ancient town of Schwarzburg-Sondershausen, in Central Germany, about 11 miles south of Erfurt, with which it is connected by rail. The Liebfrauenkirche dates from the 12th century, and contains a number of interesting monuments. There is also a castle, a palace, a town-hall, a gymnasium, and a variety of charitable institutions. The so-called Günther's Mill is worthy of notice. Leather, cloth, tobacco, weighing-machines, paper, playing cards, chairs, &c., are among the objects of its industry, and a trade is carried on in grain and wood. There are copper-mines in the neighbourhood, as well as tepid saline springs, the waters of which are used for bathing. Population, 8693.

AROK-SZÁLLÁS, a privileged market-town in Hungary, on the Gyöngyös, 44 miles E.N.E. of Pesth, with a population of 10,400, largely engaged in the transit trade to Upper Hungary.

ARONA, a town in the province of Novara, near the southern extremity of Lago Maggiore. It is well built, and has a gymnasium, an hospital, a port, and dockyard on the lake, and several churches, of which the most important is that of S. Maria, with an altar-piece by Gaudenzio Vinci. There is considerable trade with Germany and Switzerland, and red marble is quarried in the neighbourhood. Count Carlo Borromeo, canonised for his piety and benevolence, was born, in 1538, in the now ruined castle; and on an eminence overlooking the district stands the colossal statue erected in 1697 to his memory by the gratitude of the people. It was executed by Zanello of Pavia and Falcano of Lugano, and is of bronze in the head and hands and feet, and of wrought copper in the remaining portions. It is 66 feet in height, and is raised 46 feet more by its pedestal. It is hollow, and can be ascended from within; the head affords room for three or four persons, and a beautiful view is obtained through the eyes. Population, 3443.

ARPINO, a town on the River Garigliano (*Liris*), in the province of Caserta, in Italy, with a population of 10,000, engaged in the manufacture of woollen cloth, parchment, paper, &c. The first of these industries seems to have existed from a very early date, to judge by inscriptions and the dedication to Mercurius Lanarius of the temple which is replaced by the church of S. Maria di Civita. Originally a Volscian town, *Arpinum* passed into the hands of the Samnites, and from them under the dominion of Rome. Its inhabitants became "Roman citizens" in 302 B.C., and received the right of voting in 188 B.C., being enrolled in the Cornelian tribe. The town is chiefly celebrated as the birth-place of Marius and Cicero. The hereditary *villa* of the orator is supposed to have been situated in the Isola S. Paola, at the mouth of the Fibrenus, where there now stands the monastery of S. Dominico Abbate, in which Hildebrand was once a monk.

ARQUA, a little Italian town, about 13 miles S.W. of Padua, with a population of 1100, chiefly known for that connection with Petrarch which has been so finely commemorated in Byron's lines—

> "They keep his dust in Arqua, where he died."
> *Childe Harold*, cant. iv. st. 31; also st. 59.

ARQUES, a French village in the department of Seine-Inférieure, noteworthy for its castle, founded by William, the uncle of the Conqueror, which was the scene of several remarkable sieges, and gave name to the battle of 1589 in which Henry IV. of France defeated the duke of Mayenne and the Leaguers. Of the extensive and massive building almost nothing remains. The village church, dating from the 16th century, is interesting for its sculptures and stained-glass windows. Population, 968.

ARRACK, a name derived from the Arabic *arak* (perspiration), and applied to a spirituous liquor distilled in India, Ceylon, and Java, and generally consumed in Eastern countries. In Ceylon arrack is distilled from the fermented juice called toddy, drawn from the unexpanded flower-spathes of various palms, chiefly the Palmyra palm (*Borassus flabelliformis*) and the cocoa palm (*Cocos nucifera*). On the Indian continent a kind of arrack is made from the flowers of the Muohwa tree (*Bassia latifolia*), besides that derived from palm toddy; and a large quantity of a nauseous and unpalatable spirit is distilled from rice, which goes by the name of rice arrack. This spirit is consumed by the lower orders and wild tribes of Bengal and Central India. In Java arrack is distilled from the impure molasses left in the manufacture of raw sugar, fermented with rice, to which a proportion of palm toddy is added. Large quantities of the deleterious spirit so prepared is shipped from Java to the countries of Northern Europe. The habitual use of these inferior liquors in the hot countries in which they are distilled is attended with most disastrous consequences.

ARRAIGNMENT (from *arraisonner*, *arraigner*, Old Fr., *ad rationem ponere*, to call to account), a law term, properly denoting the calling of a person to answer in form of law upon an indictment. After a true bill has been found against a prisoner by the grand jury, he is called by name to the bar, the indictment is read over to him, and he is asked whether he be guilty or not of the offence charged. This is the arraignment. His plea in answer to the charge is then entered, or a plea of not guilty is entered for him if he stands mute of malice and refuses to plead. If he pleads guilty sentence may be passed forthwith; if he pleads not guilty, he is then given in charge to a jury of twelve men to inquire into the truth of the indictment. He may also plead in abatement, or to the jurisdiction, or demur on a point of law. Several defendants, charged on the same indictment, are arraigned together.

ARRAN, an island on the west coast of Scotland, near the mouth of the river Clyde, which forms part of the county of Bute. It is about 20 miles in length, by from 8 to 11 in breadth, and contains a superficial area of 165 square miles, or 105,814 acres, of which about 14,431 are cultivated. This island is rugged and mountainous, particularly in the northern part, in which the valleys are deep and romantic. The principal mountain is Goatfell (in Gaelic, Goadh-Bhein, or Mountain of the Winds), 2865 feet above the level of the sea; and a few others, as Beinn Tarsuin and Ben Noosh, approach the same elevation. There are five small lakes and several streamlets in the island. There is little cultivation, the farms being principally pastoral. A good many Highland cattle and sheep are fed on the island. Game is abundant, consisting of blackcock and grouse. A few red deer and a number of wild goats still find shelter among the mountains.

The geology of the island is an epitome of that of Scotland. The mountains of the north, especially Goatfell, consist of granite, surrounded on the flanks by micaceous and argillaceous slates; lying on the edges of the slate are well seen red sandstone and conglomerate, especially on the eastern shores, but easily traceable across the island. On the eastern side limestone, containing Carboniferous fossils, is found at several points intercalated among the red sandstones chiefly at Corrie, where several strata divided by shale are quarried. In the southern part of the island the stratified formations are overlain by a great series of trap-rocks. Several beds of coal were formerly worked on the north-east coast. This coal lies low down in the Carboniferous series, at the base of the Carboniferous limestone, or in the "calciferous sandstones." Numerous veins of most beautiful pitchstone and pitchstone-porphyry traverse the red sandstone, especially at Drimadoon and between Brodick and Lamlash. On the mountains are found jasper, agates, cairngorms, and small clear specimens of rock-crystal, called the Arran diamond.

A considerable manufacture of sulphate of baryta as a pigment was at one time carried on in Glen Sannox. The herring fishery is prosecuted by the islanders. Arran possesses two remarkably fine natural harbours,—Lamlash Bay, on the south-east of the island, and Loch Ranza on the north-west side. The latter is an indentation of the sea on the north of the island, about a mile in length, and is a place of great resort for boats engaged in the herring fishing. The ruins of an old castle stand upon a small peninsula near the entrance. Almost the whole island belongs to the duke of Hamilton, whose seat is at Brodick Castle. The landing-pier for steamers and the principal hotel are at Brodick Bay, where there is a village with church and school. Six miles from Brodick lies the village of Lamlash. Its beautiful semicircular bay, sheltered by the Holy Island, forms an excellent harbour for ships of all sizes. The Holy Isle, an irregular cone 1020 feet high, was once the site of a cell inhabited by St Molios, a disciple of St Columba. Off the south-east point of Arran lies the low rocky islet of Pladda, with a lighthouse having two fixed lights 130 and 77 feet above high water, and visible 16 and 13 miles respectively, in clear weather. It has a telegraph station, from which the arrival of vessels in the Clyde is notified to Glasgow and Greenock. Many parts of the island are traditionally connected with Robert Bruce. Thus one of the largest of the water-worn recesses in the high sandstone cliffs of the west coast is called the king's cave, another is the king's kitchen, a third his cellar, and a fourth his table, while the hill above is the king's hill; the southern extremity of Lamlash Bay is the King's Cross Point; and an ancient fort in Glencloy is said to have sheltered his men.

The antiquities of the island, besides those already mentioned, are Druidical circles (of which the most complete are at Tormore, near Drimadoon, and are called Suidhe Choior Fhionn, or Fingal's cauldron seat), Danish forts, and sepulchral cairns, such as the immense mound, 200 feet in circumference, at the head of Glen Meneadmar or Moneymore.

ARRAS (the *Nemetacum* of the Romans), a fortified city of France, chief town of the department of Pas de Calais, and formerly capital of the province of Artois. Its name, otherwise Atrecht, is like Artois, a corruption of the name of the Atrebates. It is situated on both sides of the Scarpe, where that river receives the Crinchon, 32 miles N.E. of Amiens, and 100 miles N.N.E. of Paris. The town is well built and adorned with many handsome edifices, such as the town-house, a beautiful building, dating from 1510; the cathedral (1833), on the site of the older Gothic, which was destroyed in the Revolution; the citadel, erected by Vauban, who first employed his lunettes in the defences of the town; an arsenal, barracks, a theatre, &c. It is the seat of a bishop, and of a court of assize; and has a royal society, a college, a diocesan seminary, an institution for the deaf and dumb, and schools of design and belles lettres, as well as a public library of upwards of 40,000 volumes, a picture gallery, museum, and botanical garden. Its chief manufacturers are lace, woollens, hosiery, beet-root sugar, salt, soap, and earthenware; and there is a large general trade in wine, oil, grain, &c. It was at one time so celebrated for its tapestry that in English its name became identified with the manufacture. The River Scarpe is navigable up to the town. Population in 1872, 27,329. Lat. 50° 17′ 31″ N., long. 2° 46′ 49″ E.

Arras was the chief town of the *Atrebates* as early as the time of Cæsar, and some remains of the Roman town, such as a temple of Jupiter, have been found. In 407 it was destroyed by the Vandals, and by the Normans in 880. It gives name to a treaty concluded in 1414 between the Armagnacs and Burgundians, to another between Philip the Good of Burgundy and Charles VII. of France in 1435, and to a third, in 1482, between Maximilian of Austria and Louis XI. of France, by which Burgundy and Artois were given to the Dauphin as a marriage portion. In 1493 it came again into the possession of Maximilian; and in 1578 it was held by the prince of Orange. In 1640 troops of Louis XIII. took Arras; and by the peace of the Pyrenees, in 1659, France was confirmed in the possession of the town. It suffered severely during the Revolution, especially at the hands of the infamous Lebon, who, as well as the brothers Robespierre, was born in the town.

ARREST (from the French *arrester*, *arrêter*, to stop or stay) is the restraint of a man's person, for the purpose of compelling him to be obedient to the law, and is defined to be the execution of the command of some court of record or officer of justice.

Arrests are either in civil or in criminal cases.

I. *In Civil Cases.*—The arrest must be by virtue of a precept or order out of some court, and must be effected by corporal seizing or touching the defendant's body, or as directed by the writ, *capias et attachias*, take and catch hold of. And if the defendant make his escape it is a *rescous*, or rescue, and attachment may be had against him, and the bailiff may then justify the breaking open of the house in which he is, to carry him away.

Arrests on mesne process, before judgment obtained, are abolished by 32 and 33 Vict. c. 62, § 6; an exception, however, is made in cases in which the plaintiff proves, at any time before final judgment, by evidence on oath to the satisfaction of a judge of one of the superior courts, that he has a good cause of action to the amount of £50, that the defendant is about to quit the country, and that his absence will materially prejudice the plaintiff in prosecuting his action. In such cases an order for arrest may be obtained till security to the amount of the claim be found.

Until a recent period a judgment creditor might arrest his debtor under a writ of *capias ad satisfaciendum*, but since 32 and 33 Vict. c. 62 (the Debtor's Act, 1869), imprisonment for debt has been abolished in England, except in certain cases, and in these the period of detention must not exceed one year.

The following persons are privileged from arrest, viz., 1*st*, Members of the Royal Family and the ordinary servants of the king or queen regnant, chaplains, lords of the bedchamber, &c. This privilege does not extend to servants of a queen consort or dowager. 2*d*, Peers of the realm, peeresses by birth, creation, or marriage, Scotch and Irish peers and peeresses. 3*d*, Members of the House of Commons during the session of Parliament, and for a convenient time (forty days) before and after it. Members of Convocation appear to have the same privilege. *4th*, Foreign ambassadors and their "domestics and domestic servants." Temporary privilege from arrest is enjoyed by barristers travelling on circuit, by parties, witnesses, or attorneys connected with a cause, and by clergymen whilst performing divine service.

The arrest of any privileged person is irregular *ab initio*, and the party may be discharged on motion. The only exception is as to indictable crimes, such as "treason, felony, and breach of the peace."

There are no longer any places where persons are privileged from arrest, such as the Mint, Savoy, Whitefriars, &c., on the ground of their being ancient palaces; but near the Palace of Holyrood, Edinburgh, a sanctuary still exists for the benefit of debtors, who resort there for such protection, and take lodgings within the precincts.

Except in cases of treason, felony, or breach of the peace, an arrest cannot be made on a Sunday, and if made it is void (29 Car. II. c. 7); but it may be made in the night as well as in the day.

II. *In Criminal Cases.*—All persons whatsoever are, without distinction, equally liable to this arrest, and any man may arrest without warrant or precept, and outer doors may be broken open for that purpose. The arrest may be made,—*1st*, by warrant; *2d*, by an officer without warrant; *3d*, by a private person without warrant; or, *4th*, by a hue and cry.

1. Warrants are ordinarily granted by justices of the peace on information or complaint in writing and upon oath, and they must be indorsed when it is intended they should be executed in another county (see 11 and 12 Vict. c. 42). They are also granted in cases of treason or other offence affecting the Government by the Privy Council, or one of the secretaries of state, and also by the chief or other justice of the court of Queen's bench in cases of felony, misdemeanour, or indictment found, or criminal information granted in that court. Every warrant ought to specify the offence charged, the authority under which the arrest is to be made, the person who is to execute it, and the person who is to be arrested.

2. The officers who may arrest without warrant are,—justices of the peace, for felony or breach of the peace committed in their presence; the sheriff and the coroner in their county, for felony; constables, for treason, felony, or breach of the peace committed in their view,—and within the metropolitan police district they have even larger powers; and watchmen from sunset to sunrise.

3. A private person is bound to arrest for a felony committed in his presence, under penalty of fine and imprisonment.

4. The arrest by hue and cry is where officers and private persons are concerned in *pursuing* felons, or such as have dangerously wounded others.

The remedy for a wrongful arrest is by an action for false imprisonment.

In Scotland the law of arrest in criminal procedure has a general constitutional analogy with that of England, though the practice differs with the varying character of the judicatories. Colloquially the word arrest is used in compulsory procedure for the recovery of debt; but the technical term applicable in that department is caption, and the law on the subject is generically different from that of England. There never was a practice in Scottish law corresponding with the English arrest in mesne process; but by old custom a warrant for caption could be obtained where a creditor made oath that he had reason to believe his debtor meditated flight from the country, and the writ so issued is called a warrant against a person *in meditatione fugæ*. Imprisonment of old followed on ecclesiastical cursing, and by fiction of law in later times it was not the creditor's remedy, but the punishment of a refractory person denounced rebel for disobedience to the injunctions of the law requiring fulfilment of his obligation. The system was reformed and stripped of its cumbrous fictions by an Act of the year 1837. Although the proceedings against the person could only follow on completed process, yet, by a peculiarity of the Scottish law, documents executed with certain formalities, and by special statute bills and promissory-notes, can be registered in the records of a court for execution against the person as if they were judgments of the court.

Arrest of Judgment is the assigning just reason why judgment should not pass, notwithstanding verdict given, either in civil or in criminal cases, and from intrinsic causes arising on the face of the record.

ARRESTMENT, in *Scottish Law*, denotes that process by which a creditor detains the goods or effects of his debtor in the hands of third parties till the debt due to him shall be paid. It is divided into two kinds,—*1st*, Arrestment in security, used when proceedings are commencing, or in other circumstances where a claim may become, but is not yet, enforceable; and *2d*, Arrestment in execution, following on the decree of a court, or on a registered document, under a clause or statutory power of registration, according to the custom of Scotland. By the process of arrestment the property covered by it is merely retained in its place; to realise it for the satisfaction of the creditor's claim a farther proceeding called "Forthcoming" is necessary. By old practice, alimentary funds, or those necessary for subsistence, were not liable to arrestment. By 33 and 34 Vict. c. 63, the wages of all labourers, farm-servants, manufacturers, artificers, and work-people, are not arrestable except (1) in so far as they exceed 20s. per week; but the expense of the arrestment is not to be charged against the debtor unless the sum recovered exceed the amount of the said expense; or (2) under decrees for alimentary allowances and payments, or for rates and taxes imposed by law.

ARRIA, the wife of Cæcina Pætus, who, having been engaged in the conspiracy of Scribonianus against the Emperor Claudius, 42 A.D., was condemned to death. Arria, resolving not to survive her husband, stabbed herself with a dagger, which she then handed to him with the words, "Pætus, it does not pain me." Her daughter, also called Arria, was the wife of Thrasea; and when he was condemned to death by Nero, she would have imitated her mother's example. but was dissuaded by her husband, who entreated her to live for the sake of their children. She was sent into banishment.

ARRIAN (Ἀῤῥιανός), a distinguished Greek historian and philosopher, who lived in the time of the Emperors Hadrian, Antoninus Pius, and Marcus Aurelius. He was a native of Nicomedia, born about the end of the 1st century of our era, and was one of the most distinguished disciples of the famous Epictetus. In 124 A.D. he lived at Athens, where he made the acquaintance of the Emperor Hadrian, who was so much struck with his practical wisdom as to raise him to several high offices; and under Antoninus he obtained even the consulship. The only other event of his life of which we know anything is, that he was appointed governor of Cappadocia, and in that capacity distinguished himself by the victory he gained over the Alani. Arrian proudly disdained to give any information regarding himself; and his life, written by Dion Cassius, is lost. History and philosophy are greatly indebted to Arrian; for, being a disciple of Epictetus, who himself did not write any work, Arrian determined to be to him what Xenophon had been to Socrates, and published his philosophical lectures in eight books, of which only the first half is extant: but the portion which has come down to us gives us a most exalted view of the ethical philosophy of Epictetus and the Stoics generally. The work bears the title Διατριβαὶ Ἐπικτήτου, and is contained in Schweighäuser's *Philosophiæ Epicteteæ Monumenta*, vol. iii. A second work, by which Arrian testified his attachment to his great master, bears the title Ἐγχειρίδιον Ἐπικτήτου, a short manual of moral philosophy, compiled from the lectures of Epictetus, which for many centuries was regarded both by Pagans and Christians as the best book on the subject. It has been published in a great many editions; the best is in the collection of Schweighäuser mentioned above. Of Arrian's original works the one of greatest importance is his account of the expedition of Alexander the Great in seven books. It contains the most complete and authentic account of that conqueror's career, being based upon the lost works of Aristobulus and Ptolemy, the son of Lagus, both of whom accompanied the king during the expedition. The best modern editions are those of Ellendt, 1832, 2 vols. 8vo; Krüger, Berlin, 1835 and 1848, 2 vols. 8vo, and 1851, 1 vol. 8vo; Sintenis, Lips. 1849; and Dübner and Müller, 1846. Connected with his history of Alexander is a treatise on India, in the Ionic dialect, which he wrote separately, in order not to break the continuity of the narrative. He also wrote a work on the chase, a periplus or voyage round the coasts of the Black Sea, and a manual of tactics; but of many other works ascribed to him by the ancients there are extant only a few fragments. Certain descriptions of the coasts of the Sea of Azov and the Red Sea, which are ascribed to him, are probably the productions of a later period. Arrian's style is simple, lucid, and manly. His imitation of Xenophon is visible, not only in his style and diction, but even in the subjects on which he wrote. His language, though pure Attic, presents some peculiarities which are not found in the works of his great model.

ARROWROOT. A large proportion of the edible starches obtained from the rhizomes or root-stocks of various plants are known in commerce under the name of arrowroot. Properly the name should be restricted to the

Fig. 1. Fig. 2.
Arrowroot Plant (*Maranta arundinacea*).—Fig. 1, stem, leaves, and flowers; fig. 2, roots.

starch yielded by two or three species of *Maranta*, the chief of which is *M. arundinacea*; and when genuine or West Indian arrowroot is spoken of, it is understood that this is the variety meant. *Maranta arundinacea* is originally a native of the American continent, but it has long been cultivated in the West Indian Islands, and it has now spread to most tropical countries. The plant produces a scaly, white, tuberous rhizome, and it is at the period when this organ is gorged with starch-cells, immediately before the season of rest, that it is ripe for use. In addition to about 25 per cent. of starch, the fresh roots contain a proportion of woody tissue, vegetable albumen, and various salts. The arrowroot may be separated on a small scale in the same manner as potato-starch is frequently prepared, that is, by peeling the root and grating it in water, when the starch falls to the bottom The liquor is then drained off, and the starch purified by repeated washings till it is ready for drying. On a large scale the manufacture of arrowroot is conducted with specially prepared machinery. The rhizomes when dug up are washed free of earthy impurities and afterwards skinned. Subsequently, according to Pereira's *Materia Medica*, "the carefully skinned tubers are washed, then ground in a mill, and the pulp washed in tinned-copper cylindrical washing-machines. The fecula is subsequently dried in drying-houses. In order to obtain the fecula free from impurity, pure water must be used, and great care and attention paid in every step of the process. The skinning or peeling of the tubers must be performed with great nicety, as the cuticle contains a resinous matter which imparts colour and a disagreeable flavour to the starch. German-silver palettes are used for skimming the deposited fecula, and shovels of the same metal for packing the dried fecula. The drying is effected in pans, covered with white gauze to exclude dust and insects."

Arrowroot is distinguished by the granules agglomerating into small balls, by slightly crepitating when rubbed between the fingers, and by yielding with boiling water a fine, transparent, inodorous, and pleasant-tasted jelly. In microscopic structure the granules present an ovoid form, marked with concentric lines very similar to potato-starch, but readily distinguished by having a "hilum" marking at the thick extremity of the granule, while in potato-starch the same appearance occurs at the thin end (compare figs. 3 and 4 below). In addition to the West Indian supplies, arrowroot is now found in the commerce of Brazil, the East Indies, Australia, Cape Colony, and Natal, in the last of which localities it has become a staple of some importance. Bermuda arrowroot has always been held in the highest esteem, but on those islands the cultivation is gradually giving way to more profitable crops. In 1872 only 26,710 ℔, of the value of £1323, were exported from the Bermudas, while in 1851 the value of the export trade was more than £10,000. St Vincent is now the chief seat of arrowroot culture in the West Indies.

Tous-les-mois, or Tulema arrowroot, is obtained from several species of *Canna*, a genus closely allied to *Maranta*, and cultivated in the same manner. The granules of *tous-les-mois* are readily distinguishable by their very large size (fig. 5). *East Indian arrowroot* is obtained from the root-stocks of several species of the zingiberaceous genus, *Curcuma*, chiefly *C. angustifolia*. *Brazilian arrowroot* is the starch of the cassava plant, *Jatropha Manihot* (fig. 6); which when agglutinated on hot plates forms the tapioca of commerce. The cassava is now cultivated in the East Indian Archipelago as well as in South America. *Tacca*, or *Otaheite arrowroot*, is the produce of *Tacca pinnatifida*, the Pia plant of the South Sea Islands. *Portland arrowroot* was formerly prepared on the isle of Portland from the tubers of the common Cuckoo Pint. *Arum maculatum*. Various other species of *Arum* yield valuable food-starches in hot countries. Under the name of *British arrowroot* the farina of potatoes is sometimes sold, and the French excel in the preparation of imi-

Starch Granules magnified.—Fig. 3, potato; fig. 4, arrowroot; fig. 5, tous-les-mois; fig. 6, jatropha.

tations of the more costly starches from this source. The chief use, however, of potato-farina as an edible starch is for adulterating other and more costly preparations. This falsification can readily be detected by microscopic examination, and the accompanying drawings exhibit the appearance under the microscope of the principal starches we have described. Although these starches agree in chemical composition, their value as articles of diet varies considerably, owing to different degrees of digestibility and pleasantness of taste. Arrowroot is found frequently to remain in the stomach of invalids when most other forms of food are rejected, and on this account it has considerable therapeutic value. Being destitute of nitrogen, arrowroot and the other edible starches belong to the force-producing class of foods, and cannot of themselves form a perfect diet. They require to be associated with milk, eggs, meat, or other substances rich in nitrogenous compounds as articles of diet; and they should not be given to young infants, whose organs are not suited for the digestion of starchy food.

ARROWSMITH, the name of a family of geographers. The first of them, Aaron Arrowsmith, was born in 1750 at Winston in Durham. When about twenty years of age he came to London, and was employed by Cary, the engraver. In 1790 he made himself famous by his large chart of the world on Mercator's projection. Four years later he published another large map of the world on the globular projection, with a companion volume of explanation. The maps of North America and Scotland are the most celebrated of his many later productions. He died in 1823, leaving two sons, Aaron and Samuel, the elder of whom was the compiler of the *Eton Comparative Atlas*, of a Biblical atlas, and of various manuals of geography. John Arrowsmith, nephew of the elder Aaron, was born at Winston in 1790, and in 1810 joined his uncle in London. In 1834 he published his *London Atlas*, the best set of maps then in existence. He followed up the atlas with a long series of elaborate and carefully-executed maps, those of Australia, America, Africa, and India being especially valuable. In 1862 he received the gold medal of the Royal Geographical Society, of which body he was one of the founders. He died 2d May 1873.

ARSACIDÆ, the dynasty of Parthian kings, so called from the name of the founder, Arsaces. Very little is known of the circumstances attending the sudden rise of the Parthian power, or of the leader under whom it was effected. He is said by some to have been a Parthian noble, by others to have been a predatory Scythian chief. But at all events, about 250 B.C., when the Seleucid empire of Antiochus II. was distracted by an Egyptian war and the successful rebellion of Bactria, the Parthians, hitherto subject and almost unknown to history, revolted, established an independent kingdom, and made their leader, Arsaces, their first sovereign. He is said to have been killed in battle, after a short reign of three years, and the throne was then occupied by his brother, Tiridates, who, like all succeeding sovereigns of Parthia, assumed the name Arsaces as a regal title. The empire increased rapidly in extent and strength, and for a time was the most formidable rival of the Roman power. Towards the close of the 2d century A.D. it had fallen somewhat into decay, as is manifest from the successful Roman invasions under Avidius Cassius and the Emperor Severus; and it finally succumbed to the Persians, who (224 A.D.) revolted under Artaxerxes, and slew in battle Artabanus, the twenty-ninth and last of the Arsacidæ. See PARTHIA.

ARSAMASS, a town in Russia, in the government of Nijni-Novgorod, at the confluence of two minor tributaries of the Volga, the Arsha and Tesha. It has thirty-four churches, three monasteries, several schools, and various benevolent institutions. There are dye-works, soap-factories iron-works, and extensive tanneries; and a large trade, stimulated by two annual fairs, is carried on, more especially in sheep-skins and sail-cloth. Population, 10,517.

ARSENAL (supposed to be derived from *arx navalis*, whence the Romaunt word *arthenal*, signifying generally a "citadel," though primarily it meant simply a naval citadel[1]), is an establishment for the construction, repair, receipt, storage, and issue of warlike stores.

A first class arsenal, which can renew the materiel and equipment of a large army must embrace a gun factory, carriage factory, laboratory, and small arms ammunition factory, small arms factory, harness, saddlery, and tent factories, and a powder factory; in addition it must possess great store-houses In a second class arsenal the factories would be replaced by workshops. The situation of an arsenal should be governed by strategical considerations. If of the first class, it should be situated at the base of operations and supply; it must be secure from attack, not too near a frontier, and placed so as to draw in readily the resources of the country. The defences of a large arsenal would be provided for by a chain of detached forts and an *enceinte* of sufficient strength.

Situation.

Defences.

The great point in arranging stores is their proper preservation and facility for issue. The branches of an arsenal may be divided into A, Storekeeping; B, Construction; C, Administration. Under A we should have the following departments and stores:—Departments of issue and receipt, pattern room, armoury department, ordnance or park, harness, saddlery, and accoutrements, camp equipment, tools and instruments, engineer store, magazines, raw material store, timber yard, breaking up store, unserviceable store. Under B,—Gun factory, carriage factory, laboratory, small arms factory, harness and tent factory, powder factory, &c. In a second class arsenal there would be workshops instead of these factories. C.—Under the head of administration would be classed the chief director of the arsenal, the superintendents and assistant-superintendents of the factories and branches of the arsenal. Besides these, who would usually be artillery officers, there would be required managers or foremen (civil and military), non-commissioned officers, artificers, workmen, and labourers. In addition a staff of clerks and writers are necessary for all the office work of the establishments. In the manufacturing branches we should want skill, and efficient and economical work, both executive and administrative; in the storekeeping part, good arrangement, great care, thorough knowledge of all warlike stores, both in their active and passive state, and scrupulous exactness in the custody, issue, and receipt of stores. For fuller details than can be given here the reader is referred to a paper on the organisation of an arsenal, by Lieut. Collen, R.A., in vol. viii. *Proceedings R.A. Inst.*

Organization.

In England the Royal Arsenal, Woolwich, manufactures and stores the requirements of the army and navy. Under the scheme of army localisation now in force, there are district-issuing stores for the troops for camp equipage, field stores, and reserve ammunition. The concentration of nearly the whole of our military factories and stores at one place, Woolwich, has long been considered an evil, and it has been proposed to establish, at some central spot, a large military depôt or arsenal, which should be complementary to Woolwich.

Royal Arsenal.

The history of the Royal Arsenal is treated in the paper by Lieut. Grover before referred to. As a manufacturing establishment it has existed about 150 years, but as a military post and store depôt it possesses a greater antiquity. Before 1805 it was called the "Tower Place" or King's Warren, and the land had been probably acquired in 1667

[1] See a very interesting paper by Lieut. C. E. Grover, R.E., in vol. vi. *Proceedings R. A. Inst.*, on the Royal Arsenal at Woolwich.

as sites for batteries to protect Woolwich against the invading Dutch fleet, although in 1664 mention is made of storehouses, &c., and sheds for repairing ship carriages. In 1668 guns, carriages, and stores were concentrated at Woolwich, and in 1695 the laboratory establishment was moved from Greenwich to the former place. Prior to 1716 ordnance was obtained from private manufacturers, and proved by the Board of Ordnance. In 1716 a dangerous explosion took place at the Moorfields Foundry, and it was decided to build a royal brass foundry at the Tower Place, Woolwich. Founders were advertised for, and the records of those times show that Mr Andrew Schalch of Douay was selected. The popular story of Schalch's foreseeing the explosion, and being afterwards commissioned to search for a site and build a foundry is completely disproved by Lieut. Grover. The original Tower Place consisted of 42 acres only, while the present Royal Arsenal occupies 333 acres. In 1741 an academy or school for instructing the people of the military branch of the ordnance was established at the Warren. It was not till 1805 that the collection of establishments, consisting of a foundry, laboratory, repository, &c., and stores, became the Royal Arsenal.

Having thus glanced at the history of the arsenal, we shall now endeavour to describe the various manufacturing establishments concentrated at Woolwich, and those at Enfield and Waltham.

The Woolwich establishments consist of the Royal Gun Factories, the Royal Laboratory, the Royal Carriage Department, a Chemical and Photographic establishment, a Gas Factory, and the Control Department Stores. The others are the Royal Small Arms Factory at Enfield, and the Royal Gunpowder Factory at Waltham Abbey.

Royal Gun Factories. The Royal Gun Factories consist of forges, smith's shop, rolling mills, pattern shop, brass and iron foundry, gun-boring mill, tool rooms, turneries, lighting room, field-gun section, engine repairing shop, examining branch, pattern room. The factories employ the following machinery:—291 lathes, 42 boring machines, 57 drilling machines; 12 rifling, 13 planing, 37 slotting, 64 shaping, 42 milling, 7 screwing, 3 lapping, 3 wheel cutting, and 20 weighing machines; 2 saws, 240 vices, 54 furnaces, 6 blowing fans. The total horse-power employed is—engines, 653, and boilers, 1620. Besides the elaborate machinery detailed there are no less than 86 cranes of all kinds, giving a collective power of 1172 tons, and 17 steam hammers, from 8 cwt. up to 30 tons. The average value of the work turned out is about £253,700 annually, and the department is capable of producing 6000 tons of guns of various calibres per year, or 7500 tons of forgings.

Personnel. The *personnel* consists of a superintendent and assistant-superintendent (artillery officers), deputy-assistant superintendent, 24 clerks and writers, draftsmen, proof-master and proof-sergeants, and time-keepers; 22 masters and foremen, 386 artificers, and 571 labourers and boys.

Royal Laboratory. The Royal Laboratory comprises an extensive series of factories and workshops. Under the head of small arm ammunition alone we find a paper factory, lead or bullet factory, small arms factory, containing 456 machines, and the "magazines," which include capping machines, and all those required for filling and finishing cartridges. The whole plant of 894 machines is capable of producing, in a week of fifty-four hours, 1,500,000 ball cartridges, and 500,000 blank cartridges.

Rockets. For the manufacture of rockets there is the smith's shop in the main factory, and the rocket factory in the marshes. In these, a plant of 73 machines is capable of producing, per week of fifty-four hours, 4450 rockets of all kinds.

Fuzes. The manufacture of fuzes is divided into two parts, for wood and metal fuzes. In the workshops of the former 93 machines are used, and 7000 wood fuzes can be turned out in a week. For metal fuzes are required metal turners' shops, brass foundry, paper factory, composition buildings, containing the machines for filling, pressing, and finishing fuzes. The whole plant of 142 machines and apparatus can turn out 8000 fuzes in a week.

Projectiles. For the manufacture of projectiles there are a shell foundry, brass foundry, smiths' shops, metal and turners' shops, tinman's shop, rifle shell factory, repairing and tool shop. The whole of the plant consists of 971 machines, capable of turning out weekly 6516 projectiles, field and heavy, taking the 16 pounder and the 9-inch gun as an average, and the weight of such out-turn would be 281¼ tons. The wood machinery department of the Laboratory for making powder barrels and general work consists of carpenter's shop, saw-mills, and cooperage. The plant of 116 machines can turn out 1000 small arms ammunition boxes, and 2700 barrels weekly. The torpedo factory adjoins the main factory, and contains 65 machines. For the manufacture of corrugated brass cases and zinc cylinders (to contain common cartridges), there is a metal-turner's shop capable of producing weekly 160 brass cases, and 500 zinc cases. The brass foundry can turn out 12 tons of castings weekly. Besides the above there are many miscellaneous shops and machine-rooms. In the Royal Laboratory there are 66 engines and boilers of 5155 horse-power (indicated), and a total of 2847 machines, the fuel consumed weekly by this immense establishment amounting to 93 tons. The average value of the out-turn is £472,000.

Personnel. The *personnel* consists of a superintendent and assistant-superintendent (artillery officers), 40 clerks and writers, manager and assistant-manager, 30 masters and foremen, 569 artificers, and 1772 labourers.

Royal Carriage Department. The Carriage Department manufactures all carriages, platforms, artillery machines, for the artillery, royal navy, and transport services. Its shops are as follows:—main forge, scrap forge, 6 smithies, containing in all 173 fires; 10 furnaces, with steam hammers, forging machines, &c.; 11 fitters' shops, 6 being for general work, and the remainder for work classed according to the divisions of the artillery service; general foundry, painters' shops, wheelers' shops, carpenters' shops, pattern makers' shops, saw-mills, collar makers' shops. In these different workshops there are 17 steam hammers; 16 forging machines, bolt and nut making machines, rivetting machines, &c.; 22 shearing, punching, and cutting machines; 9 planing machines; 19 shaping, 17 slotting, 10 boring and facing, 49 boring and drilling machines; 85 lathes, 17 bolt-screwing and nut-facing, 8 milling, 4 band sawing, 2 bending machines. For tin work there are 7 machines, and numerous machines for cleaning castings and turnings, grindstones, &c. For woodwork there are 43 saws of various kinds; 5 planing circular, 14 boring, 8 mortising and tenoning, 19 shaping machines; 17 lathes, and machines for sharpening saws and spoke dressing, hydraulic presses, &c. Besides these there are various miscellaneous machines. The total nominal horse-power is 250. The value of the annual out-turn is about £210,000. This department is able to turn out in one year 65 field batteries, 180 naval or garrison carriages with slides or platforms, 24 turret carriages, 360 transport carriages. In addition to this work a large quantity of repairs, conversions, and experimental work could be carried out. By working at night the out-turn could be increased 30 per cent.

Personnel. The *personnel* of the establishment consists of 1 superintendent, 1 assistant-superintendent, manager, assistant-manager, 38 clerks and writers, 38 masters and foremen, 792 artificers, 430 labourers and boys.

Store-keeping Department. In the storekeeping branch of the Arsenal, which is under the Control Department, we find 1 controller, 1 deputy-controller, 4 assistant-controllers, 2 commissaries, 7 deputy-commissaries, 8 assistant-commissaries, 5 sub-assistant-commissaries, 11 clerks and writers, 114 masters and foremen, 58 artificers, 668 labourers and boys, 60 women and girls employed.

The Royal Small Arms Factory at Enfield, and the Powder Factory at Waltham Abbey, scarcely fall under the heading *Arsenal*, but as in other countries similar factories are sometimes found within the precincts of an arsenal, and they belong theoretically to the subject, we shall speak of them here.

Royal Small Arms Factory. The factory at Enfield Lock consists of the following shops:—barrel mill, machine room, polishing room, grinding room, tempering room, tool room, smithery, millwright's room, foundry and annealing shop, joiner's shop, containing an enormous quantity of beautiful machinery worked by steam and water power. The average annual value of the work turned out is £214,482. The capability of the factory, if worked to its highest pressure, would be about 3000 arms per week with two gangs of workmen.

Personnel. The *personnel* consists of 1 superintendent and 1 assistant-superintendent (artillery officers), a chief inspector of small arms, 27 clerks, writers, and time-keepers, 1 manager, 78 masters and foremen, 715 artificers, 806 labourers and boys.

Royal Gunpowder Factory, Waltham Abbey. The Powder Factory consists of 1 saltpetre refinery, 1 house for extracting saltpetre from damaged powder, 1 sulphur refinery, 1 cylinder house with retorts for burning charcoal, 2 steam stores, 2 heading-up houses, 1 barrel house, 1 proof house, 1 mechanic's shop, houses for charcoal and composition mills, incorporating mills, breaking-down machines, press boxes with pumps, granulating machines, pellet press, glazing barrels, horizontal reels, slope reels, fire engines, and houses for all the machines required in the manufacture of gun-cotton. Both steam and water power are used. The annual value of the out-turn is £41,000. The capacity of the factory working at highest pressure would be about 30,000 barrels pebble powder per annum, or 20,000 pebble and 4000 R F.G. powder (each barrel containing 100 lb), and 150 tons gun-cotton.

Personnel. The *personnel* comprises 1 superintendent, 1 assistant-superintendent (artillery officers), 1 superintendent and 1 assistant-superintendent of machinery, 1 master worker, 1 master refiner, 9 clerks, writers, and time-keepers, 12 masters and foremen, 71 artificers, 196 labourers and boys.

There are no arsenals, properly so called, in the British colonies. The troops are supplied from stores and workshops in charge of the Control Department. In India the army is equipped and supplied by the Ordnance Departments of Bengal, Madras, and Bombay: and the arsenals come under the head of second class, being establishments for storage, issue, receipt, repair, and partial manufacture. Warlike stores are partly obtained from England, but to a great extent manufactured in the military factories of India. The chief arsenals are those of Fort William (Calcutta), Madras, Bombay, Allahabad (in the N.W. Provinces), and Ferozpore (in the Panjab). These arsenals are administered by commissaries of ordnance (artillery officers), assisted by warrant officers chosen from the army, and non-commissioned officers. Natives are employed as artificers, writers, and labourers. The native establishment is usually divided into "permanent" and "extra," the former class being permanent Government servants, and the latter merely hired according to requirements.

The detail of a chief Indian arsenal may be taken to be somewhat as follows —2 commissaries of ordnance, 10 or 12 warrant officers (conductors, &c.); 2 armourer sergeants, 9 or 10 sergeants and laboratory men, 300 to 400 native foremen, artificers, and workmen, and about 300 labourers. Besides these main arsenals, each of which supplies on an average a force of 36,000 troops of all arms, there are many minor arsenals, ordnance magazines, and ordnance depôts. In India an ordnance magazine is a place for the storage, issue, and receipt of warlike stores, and has small workshops. In by-gone days numerous ordnance establishments were necessary, but now, when means of communication by rail and road have increased so largely, there is an obvious military disadvantage in scattering military stores broadcast over the country. In India, also, the principle is observed of making regiments and batteries independent of outside aid They possess the means of executing all repairs of regimental equipment, and as the greater portion of the army of India are in possession of their camp equipage and reserve ammunition, they are able to move at short notice, while the chief arsenals at the bases of operations would form the bases of the equipment of any large force of all arms entering on a campaign. The military factories comprise—(1.) Foundry and shell factory at Cossipore, near Calcutta; (2.) Gun carriage factories at Fathighur (N.W. Provinces), Madras, and Bombay; (3.) Small arm ammunition factories at Dumdum (near Calcutta), and Kirkee (Bombay). (4.) Powder factories at Ishapore (near Calcutta), Madras, and Kirkee. (5.) Harness and saddlery factory at Cawnpore (N.W. Provinces). These factories are administered by artillery officers as superintendents, assisted by warrant officers, civil and military mechanics, native artificers, workmen, and labourers.

United States. The United States depend largely on private industry for war material, large trade factories existing for the supply of small arms and guns There were also foundries at Reading, South Boston, and Providence during th war; and arsenals of construction at Boston, New York, Washington, Bridesburg, St Louis, Alleghany, Fort Monro. These, however, have been largely reduced

France. Like most of the details of the French military organisation, the system of the supply of war material is somewhat unsettled Previous to the war of 1870–71, France possessed manufactories and arsenals for store and construction. These were not, however, placed in accordance with true strategical principles,[1] or with reference to the quick supply of the army. Thus the camp equipment was mainly stored at Paris and Versailles, and carriages at Vernon and Châteauroux. Artillery officers and men were employed in the military factories It is understood that in future each territorial district of the army will have its own arsenal or, at least, its own depôt of military stores; but while military factories are maintained, war materiel will also be drawn from private industry

Germany. The chief German arsenals are at Spandau, Cologne, Dantzig There are second class arsenals at Dresden, Ludwigsburg, Carlsruhe, Augsburg, Munich, in the confederated states, but the tendency is to reduce these; and a considerable concentration has taken place at Spandau, which now forms the great centre of the military manufactories. In every artillery garrison and fortress there are artillery depôt for the storage of materiel. The system of the German army is to make regiments as independent as possible, and with their depôt "work detachments" even re-equipment is performed. Spandau embraces a gun and projectile foundry, powder factory, laboratory, small arms factory, and a large arsenal of construction. There are also a powder factory at Neisse, small arm factories at Erfurt and Dantzig, in addition to Krupp's great factory at Essen, in Westphalia. It is said Krupp employs good workmen, and that, so far as guns and carriages are concerned, his factory can turn out three to five field batteries daily. Artillery officers are largely employed in Germany in all the work of the arsenals.

[1] *E g*, Metz and Strasbourg, containing military factories and extensive arsenals, were situated on the front line of danger.

Austria. At Vienna are united in one enormous arsenal a gun-carriage factory, laboratory, foundry, small arms factory, &c. The arsenal can turn out 300,000 to 400,000 projectiles, 1400 guns, 960 field-carriages, and harness for 1800 carriages. There is also an artillery depôt in each military district, besides laboratories, &c. Austria also draws from the trade. She has an organised service, called the Technical Artillery, for the performance of the work connected with her factories and arsenals.

Russia. Russia has made considerable strides in the improvement of her military manufactories within the last few years. She possesses small arms factories at Tonla near St Petersburgh, Sestroetz near Moscow, and at Ijewsk. There are foundries at St Petersburg and Olonetz. The arsenal at St Petersburg includes the foundry and other military establishments. The arsenals of Briansk and Kiev also contain military factories. Foundry establishments for furnishing projectiles and guns also exist at St Petersburg, Alexandro-Olonetz (government of Olonetz), Longane (government of Ekaterinoslav), Perm, Ekaterinburg, Kamensk, Nijni-Isetsk, Werkhué-Tournisk, Barentschin, Glatonstov, &c. There are imperial powder factories at Ochta (near St Petersburg), Schosta, and Kasan. There are also mobile artillery arsenals, the materiel of which is kept in time of peace at St Petersburg, Warsaw, Kiev.

Italy. Italy has small arms factories at Brescia, Torre-Annunziata near Naples, and Turin; powder factories at Fossano and Scafati. Turin is the centre of the military factories.

Spain. Spain possesses an arsenal of construction at Seville, a factory at Toledo, a foundry at Trubia, and a small arms factory at Oviedo. There are also the powder factories of Murcia and Grenada; the laboratory of Seville; and the factory of Orbaicete.

Belgium. The military factories of Belgium consist of a gun foundry and small arms foundry at Liége. Powder is supplied from a private factory at Ghent. Guns are also obtained from Krupp. At Antwerp there is an arsenal of construction and a laboratory.

Holland. Holland possesses a gun foundry at The Hague, and workshops, small arms factory, laboratory, and powder factory at Delft.

Sweden and Norway. In Sweden and Norway the materiel of war is mainly furnished from the trade.

Denmark. Denmark has a state gun foundry and a powder factory at Frederikswoerk. Warlike materiel is also drawn from the trade, but supervised by artillery officers. There are arsenals for store and repair at Copenhagen, Halleboeck, and Frederikswoerk.

Switzerland. Switzerland has a federal foundry at Aarau, and arsenals of construction at Berne and Thun, at which latter place there is also a small arms factory. (E. H. H. C.)

ARSENIC AND ITS COMPOUNDS. Although arsenic was not recognised as a metallic element till the 18th century several of its compounds were known from remote antiquity and the name ἀρσενικόν (from ἄρσην, male) was applied by Dioscorides to the yellow sulphide of arsenic, orpiment, on account of its very potent properties. To the present day the term arsenic is more frequently applied to arsenious acid (the white arsenic of commerce) than to the metallic element to which it strictly applies. Although not very abundant, arsenic is one of the most widely disseminated of all metallic elements, few sulphur ores being free from traces of it. Metallic arsenic is found native in veins in metamorphic rocks in the mining districts of Saxony and Bohemia, and other European localities, at Zmeov in Siberia, and very abundantly in the silver mines at Chanarçillo in Chili. The ores employed in the metallurgy of arsenic are mispickel or arsenical pyrites, smaltite, and cobaltite; the arsenic in the case of the two last being a bye-product of the preparation of cobalt and nickel.

Arsenic is a highly brittle metal of a steel-grey colour, and of no very great importance in the arts. It may be prepared direct from arsenical pyrites by subliming in closed retorts, but it is more commonly reduced with powdered charcoal from arsenious acid. The physical characteristics of the metal vary according to the mode of its preparation; that produced directly from pyrites being compact, crystalline, and nearly white, while the metal reduced from arsenious acid is grey and pulverulent. It is chiefly used for mixing with lead in the manufacture of small shot, the alloy dropping in rounder forms than pure lead, which produces tailed drops. Arsenic is added to iron and steel for the manufacture of chains and ornaments, the resulting combination taking a very brilliant polish; and an alloy of copper and arsenic produces a brittle grey metal of a brilliant silvery hue, used in the manufacture of buttons.

Arsenious acid, or more properly anhydride, the arsenic or white arsenic of commerce, is the form in which arsenic is chiefly produced in metallurgical operations. It is found native to a small extent, and known by the mineralogical name arsenite. The greater proportion of arsenious acid is obtained as a bye-product of the reduction of cobalt and nickel from their ores. At Reichenstein in Silesia, and Ribas in Catalonia, mispickel is worked for arsenic. From the returns received at the English Mining Record Office it appears that 5449 tons of arsenic were produced in England in 1873. More than one-third of this came from one mine in Devonshire, where the arsenical pyrites is converted into white arsenic by roasting. In the reduction of the ores, which is accomplished in reverberatory furnaces, special precautions have to be employed to defend the workman against arsenical fumes and dust. The arsenic is obtained as an impure white powder, which is sublimed till sufficiently pure; and thereafter, by sublimation at a high temperature, the product is formed into a glassy mass. This glass is at first perfectly transparent, but it soon assumes the opaque white appearance arsenic presents in commerce. Besides being the basis of most arsenical preparations and compounds, it is used in the manufacture of glass for reducing the iron oxide contained in sand. White arsenic is one of the most violent of the acrid poisons. Its toxicological relations, the tests for it, &c., will be treated of under MEDICAL JURISPRUDENCE.

Arsenic acid is prepared from arsenious acid on the manufacturing scale by oxidising with strong nitric acid. It also is poisonous, but to a less degree than arsenious acid; and it is noticed that people employed about it become very fat, without any injury to health being apparent. It is now very extensively employed in the manufacture of aniline dyes, and also as a substitute for tartaric acid in discharging colours in calico printing. Both arsenite and arseniate of soda are used as "dung-substitutes" in calico-printing. Scheele's green is an arsenite of copper, and Schweinfurth green is the aceto-arsenite of copper. Both are brilliant green pigments in extensive use, and their employment by paper-stainers has caused a good deal of excitement and unnecessary terror. The rubbing off of arsenical particles in cleaning wall-papers may be injurious to health, but there is no possibility of any arsenical exhalation arising from the walls as has been alleged.

Two sulphur compounds of arsenic—realgar and orpiment—are also of industrial importance. Realgar, or ruby sulphur, is the disulphide of arsenic; and in its native form it was known to the ancients, being the σανδαράκη of Theophrastus. It is prepared usually from arsenious acid by mixing and melting it with the required proportion of sulphur. It is used only to a limited extent as a pigment, and is a constituent of the Indian white fire used in fire signals and pyrotechny. Orpiment (*auripigmentum*), the yellow sulphide of arsenic (the ἀρσενικόν of Dioscorides), occurs native in many localities. It is, like realgar, artificially prepared by mixing arsenious acid with the requisite quantity of sulphur, and subliming the mixture. Sulphur is used in proportions varying according to the depth of yellow desired, the orpiment of commerce not being a definite chemical compound, but a mixture of arsenious acid and the yellow sulphide, the light tints sometimes containing as much as 97 per cent. of white arsenic. It forms the artists' colour called king's yellow; and in addition to some use as a common pigment, it is employed in dyeing and calico-printing. The preparations of arsenic used in pharmacy, in addition to arsenious acid, are *Liquor arsenicalis*, or Fowler's solution, the hydrochloric solution of arsenic, arseniate of iron, and the arseniate of soda.

ARSON has been defined as the malicious and wilful burning of the house of another, and is at common law an offence of the degree of felony. Some part of the house must be actually burnt; a bare intention or attempt will not constitute the offence, but the burning of any part, however trifling, is sufficient. The burning must be malicious and wilful. If a man by wilfully setting fire to his own house burn the house of his neighbour also, it will be felony. The word *house*, in the definition of the offence at common law, extends not only to dwelling-houses, "but to all out-houses which are parcel thereof, though not adjoining thereto." Barns, with corn and hay in them, though distant from a house, are within the definition.

The different varieties of the offence are specified in the statute 24 and 25 Vict. c. 97 (Malicious Injuries to Property Act). The following crimes are thereby made felonies:—(1.) Setting fire to churches or other places of divine worship; (2.) Setting fire to a dwelling-house, any person being therein; (3.) Setting fire to a house, outhouse, manufactory, farm-building, &c., with intent to impose and defraud any person; (4.) Setting fire to buildings appertaining to any railway, port, dock, or harbour; or, (5.) Setting fire to any public building. In these cases the Act provides that the person convicted shall be liable, at the discretion of the court, to be kept in penal servitude for life, or for any term not less than three years (now *five* years by the 27 and 28 Vict. c. 47), or to be imprisoned for any time not exceeding two years, with or without hard labour, and with or without solitary confinement, and, if a male under sixteen years of age, with or without whipping. Setting fire to other buildings, and setting fire to goods in buildings in such circumstances that, if the same were thereby set on fire, the offence would be felony, are subject to the punishments last enumerated, with this exception, that the period of penal servitude is limited to fourteen years. The attempt to set fire to any building, or any matter or thing (as in last offence), is to be punished in the same way. So also is the crime of setting fire to crops of hay, grass, corn, &c., but setting fire to stacks of the same, or any cultivated vegetable produce, or to peat, coals, &c., is regarded as a more serious offence, and the penal servitude may be for life. For the attempt to commit the last two offences penal servitude is limited to seven years. Setting fire to mines is visited with the full measure of penalty, and in the case of the attempt, the penal servitude is limited to fourteen years. Setting fire, or attempting to set fire to ships is punishable by the full penalties already enumerated. Setting fire to her Majesty's vessels of war is a felony punishable by death.

In Scotland the offence, equivalent to arson in England, is known by the more expressive name of wilful fire-raising. The later statutes cited above do not apply to Scotland, where the crime is punishable capitally by old consuetudinary law. The public prosecutor has the privilege, as in other such cases, of declining to demand capital punishment, and invariably does so.

ART, in the most extended and most popular sense of the word, means everything which we distinguish from Nature. Art and Nature are the two most comprehensive genera of which the human mind has formed the conception. Under the genus Nature, or the genus Art, we include all the phenomena of the universe. But as our conception of Nature is indeterminate and variable, so in some degree is our conception of Art. Nor does such ambiguity arise only because some modes of thought refer a greater number of the phenomena of the universe to the genus Nature, and others a greater number to the genus Art. It arises also because we do not strictly limit the one genus by the other. The range of the phenomena to which we point when we say Art, is never very exactly determined by the range of the other phenomena which at the same time we tacitly refer to the order of Nature. Everybody understands the general meaning of a phrase like Pope's "Blest with each grace of nature and of art." In such phrases we intend to designate familiarly as Nature all which exists independently of our study, forethought, and exertion—in other words, those phenomena in ourselves or the world which we do not originate but find; and we intend to designate familiarly as Art, all which we do not find but originate—or in other words, the phenomena which we do add by study, forethought, and exertion to those existing independently of us. But we do not use these designations consistently. Sometimes we draw an arbitrary line in the action of individuals and societies, and say, Here Nature ends and Art begins—such a law, such a practice, such an industry even, is natural, and such another is artificial; calling those natural which happen spontaneously and without much reflection, and the others artificial But this line different observers draw at different places. Sometimes we adopt views which waive the distinction altogether. One such view is that wherein all phenomena are regarded as equally natural, and the idea of Nature is extended so as to include "all the powers existing in either the outer or the inner world, and everything which exists by means of those powers." In this view Art becomes a part of Nature. It is illustrated in the familiar passage of Shakspeare, where Polixenes reminds Perdita that—

> "Nature is made better by no mean,
> But nature makes that mean: so, over that art
> Which, you say, adds to nature, is an art
> That nature makes."
> "there is an art
> Which doth mend nature,—change it, rather, but
> The art itself is nature."

A posthumous essay of Mr John Stuart Mill contains a full philosophical exposition and defence of this mode of regarding the relations of Nature and Art. Defining Nature as above, and again as a "collective name for all facts, actual and possible," that writer proceeds to say that such a definition—

"Is evidently inapplicable to some of the modes in which the word is familiarly employed. For example, it entirely conflicts with the common form of speech by which Nature is opposed to Art, and natural to artificial. For in the sense of the word Nature which has thus been defined, and which is the true scientific sense, Art is as much Nature as anything else; and everything which is artificial is natural—Art has no independent powers of its own: Art is but the employment of the powers of Nature for an end. Phenomena produced by human agency, no less than those which, as far as we are concerned, are spontaneous, depend on the properties of the elementary forces, or of the elementary substances and their compounds. The united powers of the whole human race could not create a new property of matter in general, or of any one of its species. We can only take advantage for our purposes of the properties we find. A ship floats by the same laws of specific gravity and equilibrium as a tree uprooted by the wind and blown into the water. The corn which men raise for food, grows and produces its grain by the same laws of vegetation by which the wild rose and the mountain strawberry bring forth their flowers and fruit. A house stands and holds together by the natural properties, the weight and cohesion of the materials which compose it. A steam engine works by the natural expansive force of steam, exerting a pressure upon one part of a system of arrangements, which pressure, by the mechanical properties of the lever, is transferred from that to another part, where it raises the weight or removes the obstacle brought into connection with it. In these and all other artificial operations the office of man is, as has often been remarked, a very limited one; it consists of moving things into certain places. We move objects, and by doing this, bring some things into contact which were separate, or separate others which were in contact; and by this simple change of place, natural forces previously dormant are called into action, and produce the desired effect. Even the volition which designs, the intelligence which contrives, and the muscular force which executes these movements, are themselves powers of Nature."

Another mode of thought, in some sort complementary to the last, is based on the analogy which the operations of forces external to a man bear to the operations of man himself. Study, forethought, and exertion are assigned to Nature, and her operations are called operations of Art. This view was familiar to ancient systems of philosophy, and especially to that of the Stoics. According to the report of Cicero, Nature as conceived by Zeno was a fire, and at the same time a voluntary agent having the power or art of creating things with regularity and design (naturam esse ignem artificiosum ad gignendum progredientem via). To this fire not merely creative force and systematic action were ascribed, but actual personality. Nature was "non artificiosa solum, sed plane artifex." "That which in the works of human art is done by hands, is done with much greater art by Nature, that is, by a fire which exercises an art and is the teacher of other arts." This conception of Nature as an all-generating fire, and at the same time as a personal artist both teaching and including in her own activity all the human arts, on the one hand may be said, with Polixenes and Mr Mill, to merge Art in Nature; but on the other hand it finds the essence of Nature in the resemblance of her operations to those of Art. "It is the *proprium* of art," according to the same system, "to create and beget," and the reasoning proceeds—Nature creates and begets, therefore Nature is an artist or Demiurgus.

But these modes of thought by which Art is included under Nature, or Nature identified with Art, or both at once, are exceptional. In ordinary use the two conceptions, each of them somewhat vague and inexact, are antithetical. Their antithesis was what Dr Johnson had chiefly in his mind when he defined Art as "the power of doing something which is not taught by Nature or by instinct." But this definition is insufficient, because the abstract word Art, whether used of all arts at once or of one at a time, is a name not only for the power of doing something, but for the exercise of the power; and not only for the exercise of the power, but for the rules according to which it is exercised; and not only for the rules, but for the result. Painting, for instance, is an art, and the idea includes not only the power to paint, but the act of painting; and not only the act, but the laws for performing the act rightly; and not only all these, but the material consequences of the act or the thing painted. So of agriculture, navigation, and the rest. Exception might also be taken to Dr Johnson's definition on the ground that it excludes all actions of instinct from the genus Art, whereas usage has in more languages than one given the name of Art to several of those ingenuities in the lower animals which popular theory at the same time declares to be instinctive. Dante, for instance, speaks of boughs shaken by the wind, but not so violently as to make the birds forego their Art,—

> "Non però dal lor esser dritto sparte
> Tanto, che gl'augelletti per lor cime
> Lasciasser d'operar ogni lor *arte.*"

And Fontenelle, speaking the language not of poetry but of science :—"Most animals—as, for instance, bees, spiders, and beavers—have a kind of art peculiar to themselves; but each race of animals has no more than one art, and this one has had no first inventor among the race. Man, on the other hand, has an infinity of different arts which were not born with his race, and of which the glory is his own." Dr Johnson might reply that those properties of variety and of originality or individual invention, which Fontenelle himself alleges in the ingenuities of man but not in those of the lower animals, are sufficient to make a generic difference, and to establish the impropriety of calling a honeycomb or a spider's web a work of Art. It is not our purpose to trespass on ground so debateable as that of the nature of consciousness in the lower animals. Enough that when we use the term Art of any action, it is because we are thinking of properties in the action from which we infer, whether justly or not, that the agent voluntarily and designedly puts forth skill for known ends and by regular and uniform methods. If, then, we were called upon to frame a general definition of Art, leaving room for every accepted usage of the word, it would run thus :—*Every regulated operation or dexterity by which organised beings pursue ends which they know beforehand, together with the rules and the result of every such operation or dexterity.*

Here it will be well to consider very briefly the natural history of the name which has been given to this very comprehensive conception by the principal branches of civilised mankind. Our own word Art the English language has taken, as all the Romance languages of modern Europe have taken theirs, directly from the Latin. The Latin *ars* proceeds from a root the primitive force of which is open to question. One distinguished philologist thinks that this syllable AR, in that root from which *ars* is descended, means to plough, and is the same as appears in the Greek ἀρ-οῦν, ἄρ-οτρον, ἄρ-ουρα, and Latin *ar-are, ar-atrum, arvum* "As agriculture was the principal labour in that early state of society when we must have supposed most of our Aryan words to have been formed and applied to their definite meanings, we may well understand how a word which originally meant this special kind of labour was after wards used to signify labour in general. . . . . . And as ploughing was not only one of the earliest kinds of labour, but also one of the most primitive arts, I have no doubt that the Latin *ars, artis,* and our own word *art,* meant originally the art of all arts, first taught by the goddess of all wisdom, the art of cultivating the land."—(Max Müller, *Lect. on Science of Language,* i. 294.) The more common supposition refers the word to a root AR, of which the primitive signification will have been to put or fit two things together, and which is to be found in a large family of Greek words, such as ἀράρ-ισκε, ἀρ-μένος, ἄρ-θρον, ἀρ-ιθμος, ἀρ-τύω, κ.τ.λ. As a question of historical probability, the latter account seems the likelier, inasmuch as predatory and nomadic man was certainly in possession of many dexterities, as that of fitting a stone arrow-head to its shaft,—or say, that of putting two and two together,—from which, rather than from the later invention of agriculture, the group of human dexterities in general is likely to have received its name.

The Greek τέχνη, the name both for arts in the particular and art in the abstract, is by its root related both to τέκ-των and τέκ-νον, and thus contains the allied ideas of making and begetting. The *proprium* of art in the logic of the Stoics "to create and beget" (see above) was strictly in accordance with this etymology.

The Teutonic *Kunst* is formed from *können,* and *können* is developed from a primitive *Ich kann.* In *kann* philology recognises a preterite form of a lost verb, of which we find the traces in *Kin-d,* a child; and the form *Ich kann,* thus meaning originally "I begot," contains the germ of the two several developments,—*konnen,* "to be master," "to be able," and *kennen,* "to know."

Putting by, then, as too doubtful the etymology of *ars* from ploughing, we see that the chief Aryan languages have with one consent extended a name for the most elementary exercise of a constructive or productive power, till that name has covered the whole province of the skilled and deliberate operations of sentient beings.

In proportion as men left out of sight the idea of creation, of constructing or producing, "artificiosum esse ad gignendum," which is the primitive half of this extended notion, and attended only to the idea of skill, of proceeding by regular and disciplined methods, "progredi via," which is the superadded half, the whole notion Art, and the name for it, might become subject to a process of thought which, if analysed, would be like this :—What is done by regular and disciplined methods is Art; facts are observed and classified, and a systematic view of the order of the universe obtained, by regular and disciplined methods; the observing and classifying of facts, and obtaining a systematic view of the order of the universe, is therefore Art. To a partial extent this did unconsciously take place. Science, of which the essence is only in knowledge and contemplation, came to be spoken of as Art, of which the essence is all in practice and production. Cicero, notwithstanding his citation of the Stoical dictum that practice and production were of the essence of Art, elsewhere divides Art into two kinds—one by which things are only contemplated in the mind, another by which something is produced and done. ("Quumque artium aliud eiusmodi sit, ut tantummodo rem cernat; aliud, ut moliatur aliquid et faciat."—*Acad.* ii. 7.) Of the former kind his instance is geometry; of the latter the art of the violin player. Now geometry, understanding by geometry an acquisition of the mind, that is, a collected body of observations and deductions concerning the properties of space and magnitude, is a science and not an art; although there is an art of the geometer, which is the skill by which he solves any given problem in his science, and the rules of that skill, and his exertion in putting it forth. And so every science has its instrumental art or practical discipline; and in as far as the word Art is used only of the practical discipline or dexterity of the geometer, the astronomer, the logician, the grammarian, or other person whose business it is to collect and classify facts for contemplation, in so far the usage is just. The same justification may be extended to another usage, whereby in Latin, and some of its derivative languages, the name Art came to be transferred in a concrete sense to the body of rules, the written code or manual, which lays down the discipline and regulates the dexterity; as *ars grammatica, ars rhetorica,* and the rest. But when the word is stretched so as to mean the sciences themselves as acquisitions of the mind, that meaning is illegitimate. Whether or not Cicero, in the passage above quoted, had in his mind the science of geometry as a collected body of observations and deductions, it is certain that the Ciceronian phrase of the *liberal arts*, the *ingenuous arts*, both in Latin and its derivatives or translations in modern speech, has been used currently to denote the sciences themselves, and not merely the disciplines instrumental to them. The *trivium* and the *quadrivium* (grammar, logic, and rhetoric—geometry, astronomy, music, and arithmetic) have been habitually called arts, when some of them have been named in that sense in which they mean not arts but sciences, "only contemplating things in the mind." In the German language particularly the words Art and Science have in general been loosely interchanged. The etymology of the word for Art secured a long continuance for this ambiguity. *Kunst* was employed indiscriminately in both the senses of the primitive *Ich kann*, to signify what I know, or Science, and what I can do, or Art. It was not till the end of the 17th century that a separate word for Science, the modern *Wissenschaft*, came into use. On the other hand, the Greek word τέχνη, with its distinct suggestion of the root signification to make or get, acted probably as a safeguard against this tendency. The distinction between τέχνη, Art or practice, and ἐπιστήμη, knowledge or Science, is observed, though not systematically, in Greek philosophy. But for our present purpose, that of making clear the true relation between the one conception and the other, further quotation is rendered superfluous by the discussion the subject has received at the hands of the modern writer already quoted. Between Art, of which we practise the rules, and Science, of which we entertain the doctrines, Mr Mill establishes the difference in the simplest shape, by pointing out that one grammatical mood is proper for the conclusions of Science, and another for those of Art. Science enunciates her conclusions in the indicative mood, whereas "the imperative is the characteristic of Art, as distinguished from Science." And as Art utters her conclusions in her own form, so she supplies the substance of her own major premise.

"Every art has one first principle, or general major premise, not borrowed from science, that which enunciates the object aimed at, and affirms it to be a desirable object. The builder's art assumes that it is desirable to have buildings; architecture (as one of the fine arts) that it is desirable to have them beautiful and imposing. The hygienic and medical arts assume, the one that the preservation of health, the other that the cure of disease, are fitting and desirable ends. These are not propositions of science. Propositions of science assert a matter of fact—an existence, a co-existence, a succession, or a resemblance. The propositions now spoken of do not assert that anything is, but enjoin or recommend that something should be. They are a class by themselves. A proposition of which the predicate is expressed by the words *ought* or *should be* is generically different from one which is expressed by *is* or *will be.*"

And the logical relation of Art and Science, in other words, the manner of framing the intermediate member between the general major premise of Art and its imperative conclusion, is thus defined :—

"The Art [in any given case] proposes to itself an end to be attained, defines the end, and hands it over to the Science. The Science receives it, considers it as a phenomenon or effect to be studied, and having investigated its causes and conditions, sends it back to Art with a theorem of the causes and combinations by which it could be produced. Art then examines these combinations of circumstances, and according as any of them are or are not in human power, pronounces the end attainable or not. The only one of the premises, therefore, which Art supplies, is the original major premise, which asserts that the attainment of the given end is desirable. Science, then, lends to Art the proposition (obtained by a series of inductions or deductions) that the performance of certain actions will attain the end. From these premises Art concludes that the performance of these actions is desirable, and finding it also practicable, converts the theorem into a rule or precept . . . . The grounds, then, of every rule of Art are to be found in the theorems of Science. An Art, or a body of Art, consists of the rules, together with as much of the speculative propositions as comprises the justification of these rules. The complete Art of any matter includes a selection of such a portion from the Science as is necessary to show on what conditions the effects, which the Art aims at producing, depend. And Art in general consists of the truths of Science arranged in the most convenient order for practice, instead of the order which is most convenient for thought. Science groups and arranges its truths so as to enable us to take in at one view as much as possible of the general order of the universe. Art, though it must assume the same general laws, follows them only into such of their detailed consequences as have led to the formation of rules of conduct, and brings together from parts of the field of Science most remote from one another, the truths relating to the production of the different and heterogeneous causes necessary to each effect which the exigencies of practical life require to be produced."—(Mill's *Logic*, vol. ii. pp. 542-549.)

The whole discussion may be summed up thus. Science consists in knowing, Art consists in doing. What I must do in order to know, is Art subordinate to or concerned in Science. What I must know in order to do, is Science subordinate to or concerned in Art.

Art, then, is defined by two broad distinctions: first, its popular distinction from Nature; and next, its practical and scientific distinction from Science. Both of these distinctions are observed in the terms of our definition given above. Within the proper limits of this definition, the conception of Art, and the use of the word for it, have undergone sundry variations. These variations correspond to certain vicissitudes or developments in the order of historical facts and in society. It remains very briefly to consider the chief of these. The requirements of society, stimulating the ingenuity of its individual members, have led to the invention of arts and groups of arts, constantly progressing, with the progress of civilisation, in number, in complexity, and in resource. The religious imagination of early societies, who find themselves in possession of such an art or group of arts, forgets the history of the invention, and assigns it to the inspiration or special grace of some god or hero. So the Greeks assigned the arts of agriculture to Triptolemus, those of spinning and navigation to Athene, and of music to Apollo. At one stage of civilisation one art or group of arts is held in higher esteem, another at another. In societies, like most of those of the ancient world, where slaves were employed in domestic service, and upon the handicrafts supplying the immediate utilities of life—food, shelter, and clothing—these constituted a group of servile arts. The arts of husbandry or agriculture, on the other hand, have alternately been regarded as servile and as honourable according as their exercise has been in the hands of a subject class, as under feudal institutions, or, as under the Roman republic, of free cultivators. Under feudal institutions, or in a society in a state of permanent war, the allied arts of war and of government have been held the only honourable class. In commercial states, like the republics of Italy, the arts of gain, or of production (other than agricultural) and distribution, have made good their title to equal estimation and greater power beside the art of captains. But among peaceful arts, industries, or trades, some have always been held to be of higher and others of lower rank; the higher rank being assigned to those that required larger operations, higher training, or more thoughtful conduct, and yielded ampler returns—the lower rank to those which called for simple manual exercise, especially if such exercise was of a disagreeable or degrading kind. In the cities of Italy, where both commerce and manufactures were for the first time organised on a considerable scale, the name *arte*, Art, was retained to designate the guilds or corporations by which the several industries were exercised; and, according to the nature of the industry, the art was classed as higher or lower (*maggiore* and *minore*).

The arts of which we have hitherto spoken have arisen from positive requirements, and supply what are strictly utilities, in societies, not excluding the art of war, at least so far as concerns one-half of war, the defensive half. But war continued to be an honourable pursuit, because it was a pursuit associated with birth, power, and wealth, as well as with the virtue of courage, in cases where it had no longer the plea of utility, but was purely aggressive or predatory; and the arts of the chase have stood in this respect in an analogous position to those of war.

There are other arts which have not had their origin in positive practical needs, but have been practised from the first for pleasure or amusement. The most primitive human beings of whom we have any knowledge, the cave-dwellers of the palæolithic period, had not only the useful art of chipping stones into spear-heads, knife-heads, and arrow-heads, and making shafts or handles of these implements out of bone; they had also the ornamental art of scratching upon the bone handle the outlines of the animals they saw—mammoth, rhinoceros, or reindeer—or of carving such a handle into a rude resemblance of one of these animals. Here we have a skill exercised, in the first case, for pure fancy or pleasure, and in the second, for adding an element of fancy or pleasure to an element of utility. Here, therefore, is the germ of all those arts which produce imitations of natural objects for purposes of entertainment or delight, as painting, sculpture, and their subordinates; and of all those which fashion useful objects in one way rather than another because the one way gives pleasure and the other does not, as architecture and the subordinate decorative arts of furniture, pottery, and the rest. Arts that work in a kindred way with different materials are those of dancing and music. Dancing works with the physical movements of human beings. Music works with sound. Between that imitative and plastic subdivision, and the subdivision of these which only produce motion or sound and pass away, there is the intermediate subdivision of eloquence and the drama, which deal with the expression of human feeling in spoken words and acted gestures. There is also the comprehensive art of poetry, which works with the material of written words, and can ideally represent the effects proper to any or all of the other arts. All of these arts have, as a matter of history, been at one time or another intimately associated with religion. Painting, sculpture, architecture, drawing, music, poetry, have all been at one time or another principally devoted to the honour of supernatural beings imagined to have power over mankind for good and evil. But this use, though a part of their history, is not inseparable from their nature. What is inseparable from them, and essential to the nature of this group of arts, is twofold. First, of their effect upon those to whom they are addressed: there are certain highly complex properties and relations of rhythm, proportion, and harmony, upon which the pleasurableness of these arts depends, and which each of them, if its appeal to the perceptions and the imagination is to be successful, is bound to observe. Secondly, of the mode in which they are practised: these complex effects can only be produced by the exercise of an equally complex set of faculties in the artist; it is therefore of the essence of this group of arts, that they cannot be practised by habit, rote, or calculation; habit, rote, and calculation may help the artist a certain way, but in the essential parts of his art he passes beyond the reach of rules, and acts by what is called inspiration, that is, by the spontaneous and unreasoned working together of infinitely complex and highly developed sensibilities and dexterities in his constitution.

We shall not concern ourselves with the many definitions that have been framed by thinkers seeking to classify these arts either according to simple observation and comparison, or according to the principles each of his chosen metaphysical system. (For an account of these matters, see articles Æsthetics and Fine Arts.) Enough that together with the useful arts, there exists this great group of arts of which the end is not use, but pleasure, or pleasure before use, or at least pleasure and use conjointly. In modern language, there has grown up a usage which has not only put these and their congeners into a class by themselves, but sometimes appropriates to them alone the use of the generic word Art, as if they and they only were the arts, κατ' ἐξοχήν. First as the liberal or polite arts, and then as the fine arts, the languages of modern Europe have separated from the class of arts which exist only for use the class which exist only or chiefly for pleasure. They have gone further, and have reduced the number which the class-word is meant to include. When Art is now currently spoken of in this sense, not even music or poetry is frequently denoted, but only architecture, sculpture, and painting by themselves, or with their subordinate and decorative branches. And in correspondence with this usage, another usage has removed from the class of *arts*, and put into a contrasted class of *manufactures*, a large number of industries and their products, to which the generic term Art, according to our definition, properly applies. That definition covers the mechanical arts, which can be efficiently exercised by mere habit, rote, or calculation, just as well as the fine arts, which have to be exercised by a higher order of powers. But the word Art, becoming appropriated to the fine arts, has been treated as if it necessarily carried along with it, and as if works to be called works of art must necessarily possess, the attributes of individual skill and invention expressing themselves in ever new combinations of pleasurable contrivance. The progress of what an older nomenclature called the mechanical arts—the consequence of inventions for making production easier and more rapid by the application of physical agencies and the economising of human labour—has led to the multiplication of products all alike, all equally bearing the stamp of habit, rote, and calculation, and all equally destitute of those properties of individual contrivance and pleasureableness. And so works of Manufacture, or the products of machinery, which bear only very dully and remotely the mark of their original source in the hand and brain of man, have come to be contrasted with works of Art which bear such marks vividly and directly. For a century the mechanical kingdom, or reign of pure Manufacture, had spread apace in Europe, engrossing an ever larger field of human production. Of late years there is a sign of a reaction in favour of an extension of the kingdom of Art, or at least of endeavours to bring reconciliation and alliance between the two. (S. C.)

ART and PART, a term used in Scottish Law to denote the aiding or abetting in the perpetration of a crime,—the being an accessory before or at the perpetration of the crime. There is no such offence recognised in Scotland as that of being an accessory after the fact.

ARTA (Narda, *i.e.*, ἐν Ἄρδα, or Zarta, *i.e.*, εἰς Ἄρτα, the ancient Ambracia), a town of Albania, in the eyalet of Joannina, deriving its present designation from a corruption of the name of the river Arachthus on which it stands. It is a place of some six or seven thousand inhabitants, who are mostly Greek. There are a few remains of its old cyclopic walls; and the town contains a castle, built on the lofty site of the ancient citadel by Nicephorus (1357); a palace belonging to the Greek Metropolitan; and a number of mosques, synagogues, and churches, the most remarkable being the church of the Virgin of Consolation, founded (1071) by Michael Ducas. The streets of the town were widened and improved in 1869. Manufacture of woollens, cottons, Russian leather, and embroidery is carried on, and there is trade in cattle, wine, tobacco, hemp, hides, and grain. Much of the neighbouring plain is very fertile, and the town is surrounded with gardens and orchards, in which the orange, lemon, and citron come to great perfection. In 1083 Arta was taken by Bohemund of Tarentum; in 1449 it fell into the hands of the Turks, and in 1688 it was captured by the Venetians. In 1797 it was held by the French, but in the following year, 1798, Ali Pasha of Joannina made himself master of it. During the Greek struggle for independence it suffered severely, and was the scene of several conflicts, in which the ultimate success was with the Turks. An insurrection in 1854 was at once repressed.

ARTA (*Arachthus*), a river of Albania, which rises partly in Mount Lakmon, and partly in the heights between Lingon and Mitzekeli, flows south for upwards of forty miles along the eastern side of the Kilberini Mountains, and falls into the Gulf of Arta.

ARTA, GULF OF, the *Sinus Ambracius* of the ancients, is a large and beautiful inlet of the Ionian sea, twenty-five miles long and ten broad, the northern shores of which belong to Turkey, and the southern and eastern to Greece. Its only important affluent, besides the Arta, is the Luro (*Charadra*) also from the north. It abounds with mullets, soles, and eels. Around its shores are numerous ruins of ancient cities, as well as several flourishing modern towns, of which may be mentioned *Actium* at the entrance, *Nicopolis*, Previsa, Arta, *Argos*, Limnæa, Karavasaras, *Olpæ*, and Vonitza.

ARTAXERXES, a royal Persian name, borne first by several of the kings of the Achæmenian dynasty of the Persian empire, and found also in the later Sassanian dynasty. The original and native form of the name, as ascertained from the cuneiform inscriptions of ancient Persia, is *Artakhshatra* (see Rawlinson, *Jour. Asiat. Soc.* xi p. 35). The Hebrew transcript, occurring with slight differences of spelling in different passages of the Old Testament, is *Artakhshasta*—the Assyrian, *Sartakhshatra*—the Scythic, *Irtaksassa*,—all closely answering to the original. The Greek Ἀρταξέρξης, from which the English form is taken, is less correct, and is misleading through the assimilation of the latter part of the name to the other royal name Xerxes, with which the word before us has etymologically no connection In later times the name assumes the slightly modified forms of *Artachshetr* (De Sacy, *Antiquités de la Perse*, p. 100), and *Ardeshir* (Ἀρταξάρης and Ἀρταξήρ, in Agathias). In regard to the etymology and meaning of the name there is a general consensus of opinion among modern scholars. Herodotus (vi. 98) was misled by the Greek transcription, when, having rendered Xerxes, *Warrior* (ἀρήιος), he rendered Artaxerxes, *Great Warrior* (μέγας ἀρήιος). The elements of the name are *arta*, an intensive particle or adjective, connected with the Zend *areta*, high or honoured (in Skr. *rita*); and *khshatra*, kingdom or dominion, which occurs both in Zend and Sanscrit (Rawlinson, *Jour Asiat. Soc.*, xi. 35; Lassen, *Ueber die Keilinschriften*, p. 161; Oppert, *Les inscriptions des Achéménides*, p. 299; Spiegel, *Die altpersischen Keilinschriften*, p. 185). Lassen translates the name, Exalted in dominion

It is known that throne-names, or names appropriated to royalty, were in use among the Persians as among other Eastern nations (*cf.* Heeren, *Ideen*, i pp 138, 401, Baehr's *Ctesias*, p. 195). Thus the great Cyrus is said to have been called Agradatus before his accession to the throne. The second and third Darius had both also private names, the one Ochus, and the other Codomannus. To the class of royal names belongs the name Artaxerxes To this use its significance is alone suitable, and in the earliest times, at least, it is not found appropriated by any save either the possessors of, or the pretenders to, royalty. In regard to the most of those about to be mentioned, we have express testimony that they took this name only when they ascended the throne.

It will be convenient first to mention the Achæmenian kings thus designated in the Greek historians and the old Persian inscriptions, and then consider the questions connected with the identification of these with the kings of this name occurring in Scripture.

1. Artaxerxes, surnamed Μακρόχειρ, or Longimanus (by Persian authors, Diraz-dest), the long-handed, so called, says Plutarch (*Vita Artax.*, i.), because his right hand was longer than his left, or perhaps (see Malcolm, *Hist. of Persia*, i. p. 66) the long-armed (*cf.* Edward Longshanks), was the son of the famous Xerxes, the invader of Greece, and succeeded his father in 465 B.C. According to Josephus (*Ant. Jud.*, xi. 6, 1), he was originally called Cyrus. His reign was marked by the revolt of Egypt under Inarus, in which the Athenians were abettors of the Egyptians, and which was quelled by the Persian general Megabyzus, in 455 B.C.; and by the ratification of the peace of Callias with Athens in 449 B.C Of the architectural and inscribed remains of the ancient Persian empire very little is recognisable as due to this king. He is recorded in an inscription by his grandson, the next Artaxerxes, as the *repairer* (?) of the palace at Susa (Loftus, *Chaldæa and Susiana*, p. 372; Norris, *Jour. Asiat. Soc*, xv. pp. 157-162). There is extant a fragmentary inscription in old Persian, with an Assyrian translation, which seems to have proceeded from him; and a legend upon a vase at Venice, of Egyptian origin, which reads "Artaxerxes the great king," may with considerable assurance be also referred to this monarch (Oppert, *op. cit.* pp. 288-290). Artaxerxes died in 425 B C. after a reign of forty years.

2. The next sovereign that falls to be noticed here was the grandson of the preceding, and the son of the intermediate monarch, Darius Nothus. His original and private name was Arsaces, and he assumed that of Artaxerxes on ascending the throne (Ctesias, *Exc. Pers.* § 57; Plutarch, *Vita Artax*, c. 2). The date of his accession is 405 B.C. It is this Artaxerxes, commonly surnamed Mnemon, from the retentiveness of his memory, whose reign was distinguished by the attempt of his brother, the younger Cyrus, to gain possession of the crown, and by the victory of Cunaxa 401 B.C., the death of Cyrus, and the retreat of the ten thousand Greeks, immortalised by Xenophon. Other prominent events of this reign were the peace of Antalcidas in 399 B C., and the Cyprian revolt, with the defeat of Evagoras its leader, about 380 B.C. Artaxerxes Mnemon died in 359 B C., after a reign of forty-six years The Greek sources for this reign are comparatively abundant. Besides Xenophon, Ctesias, Diodorus, and others, Plutarch has furnished a special life of this monarch The only native memorial of his reign is the inscription already referred to, found at Susa on the bases of pillars belonging to the royal residence there, which runs thus—"Says Artaxerxes, the great King, the King of Kings, the King of the countries, the King of this earth, the son of King Darius; Darius was the son of King Artaxerxes, Artaxerxes was the son of Xerxes, Xerxes was the son of King Darius, Darius was the son of Hystaspes, the Achæmenian. Darius, my ancestor, built this temple (or edifice), and afterwards it was repaired (?) by Artaxerxes, my grandfather. By the help of Ahuramazda I placed Anahita and Mithra in this temple. May Ahuramazda, Anahita, and Mithra protect me." (See Norris in Loftus, *op. cit.* p 372, *Jour. Asiat. Soc.*, xv p. 159; Spiegel, *op. cit* p. 65.) The inscription, compared with earlier texts, shows a certain negligence of style, and is interesting for the prominence, unparalleled in previous records, given to the worship of the subordinate deities Anahita, or Tanaitis, and Mithra.

3 This sovereign was succeeded by his son Ochus, who, on securing the crown, took the same royal name, and is usually known as Artaxerxes Ochus. The commencement

of his reign was marked by numerous formidable revolts throughout the western provinces of the empire, which, however, were vigorously repressed, and after the re-subjugation of the revolted countries, the power of the empire was advanced to an extent and to an apparent stability unequalled since the time of the great Darius. This Artaxerxes perished by poison in 338 B.C. He is known as the builder of one of the palatial structures which stood on the platform of Persepolis; and an inscription proceeding from him (wrongly ascribed to the previous Artaxerxes by Benfey, *Die persischen Keilinschriften*, p. 67) has been found there, marked, like that already spoken of, and to a greater degree, by defects of style, and presenting his genealogy in entire accordance with the preceding. (See Rawlinson, *op. cit.* x. p. 341; Oppert, *op. cit.* p. 297; Spiegel, *op. cit.* p. 67.)

4. We find yet another instance in the classical writers of the use of Artaxerxes as a royal name during the Achæmenian period. After Darius Codomannus, the successor of Artaxerxes Ochus, had been finally and decisively defeated by Alexander at Arbela, he was, while fleeing before the conqueror, traitorously slain by Bessus, the satrap of Bactria, who thereupon, we are told, "assumed the upright tiara and the royal robe, and the name Artaxerxes instead of Bessus, proclaiming himself king of Asia" (Arrian, *Exp. Alex.*, iii. 25, 3, *cf.* Curtius, vi. 6, 13).

Such are the Achæmenian kings known to the classical writers by the name Artaxerxes. But the name also occurs in the Scriptural books of Ezra and Nehemiah, as well as in some of the Apocryphal books, and in Josephus; and it remains to be considered whether the persons there referred to are to be identified with any of the kings now mentioned, and if so, with whom? In the book of Nehemiah, Artaxerxes, king of Persia, appears as the monarch to whom Nehemiah acted as cup-bearer (i. 2), from whom he received a commission, in the twentieth year of the king, to rebuild the wall and other ruined edifices in Jerusalem (ii. 1), and whose thirty-second year is also mentioned (v. 14, xiii. 6). In attempting to identify this Artaxerxes with one of those above named, our choice is at once limited by the length of his reign to those surnamed Longimanus and Mnemon. A sufficient proof that it is the former of these who is meant, is found in the genealogy of Eliashib, the high priest when Nehemiah came to Jerusalem (Neh. iii. 1, and xii. 10). For Eliashib was the grandson of Jeshua, and Jeshua was high priest when Zerubbabel led the first company of returned exiles to Judah, in the days of Cyrus (Ezra ii. 2, iii. 2). Now, the reign of Cyrus dates from 536 B.C.; and from this to the twentieth year of Artaxerxes Longimanus, or 445 B.C., is a period of ninety-one years, leaving room for precisely three generations. The opinion, which is the common one, that the Artaxerxes of Nehemiah is Artaxerxes Longimanus, is thus fully warranted (though some, as De Saulcy, *Sept siècles de l'histoire judaique*, p. 28, identify him with Artaxerxes Mnemon), and this enables us to proceed with confidence when inquiring into the reference of the name as it occurs in the book of Ezra. Ezra was contemporary with Nehemiah (Neh. viii. 1), and mention is made in his book of an Artaxerxes who was his own contemporary (Ezra vii. 1, 7, 11; viii. 1), in whose seventh year a decree was issued, giving authority to Ezra to levy whatever supplies were needful for the service of the temple at Jerusalem. This, therefore, must have been also Artaxerxes Longimanus, and the year referred to is 458 B.C. Hence, also, when it is said (Ezra vi. 14) that "the elders of the Jews builded, and they prospered, . . . according to the commandment of Cyrus, and Darius, and Artaxerxes king of Persia," it may without difficulty be understood that the same monarch is here named, the writer singling out the three kings who, of all the Persian monarchs, distinguished themselves by the favour shown to the Jews.

The name occurs again in an earlier part of the same book, chapter iv. In verse 5 of that chapter mention is made of efforts of the enemies of the Jews to hinder the rebuilding of the temple, put forth "all the days of Cyrus, king of Persia, even until the reign of Darius, king of Persia." Then in the two succeeding verses Ahasuerus and Artaxerxes are specified as kings in whose reigns representations adverse to the Jews were made at the court of Persia; and after the detailed accounts of the second of these representations, and its success with Artaxerxes, it is said (ver. 24), "Then ceased the work of the house of God which is at Jerusalem. So it ceased unto the second year of Darius, king of Persia." The narrative has all the appearance of consecutive history, and the natural interpretation obviously is that the two kings, Ahasuerus and Artaxerxes, intervened between Cyrus and Darius. It is true, mention is made in the memorial presented to king Artaxerxes of the building of the city and the walls, rather than of the temple, the rebuilding of which was at the time the great enterprise of the returned exiles; but this may be easily accounted for, from the interest of the writers to make out the strongest possible case at the Persian court. Besides, it is impossible to believe that the city and its walls remained utterly desolate as the Chaldeans had left them while the temple was being rebuilt. There is, indeed, express testimony to the contrary. Notice is taken of the "ceiled houses" of Jerusalem at this period (Haggai i. 4). Mention is also made of a "wall" of defence for its inhabitants (Ezra ix. 9), and Josephus (*Ant. Jud.*, xi. 4, 4) records the "strong walls about the city" while the temple was still unfinished. It has indeed been argued, and that quite reasonably, that the wall mentioned in Nehemiah i. 3, which was reported to Nehemiah as "broken down," is that to which reference is made in the passages just cited from Ezra and Josephus, built by the first colony of returned Jews, and not that destroyed by the Chaldeans nearly a century and a half before (see Kitto's *Cyclopædia*, article "Ahasuerus"). There seems, therefore, to be nothing in the narrative to hinder the two kings to whom it relates, and whom it places between Cyrus and Darius, from being identified with the two kings who did actually intervene between these monarchs, viz., Cambyses and the pseudo-Smerdis; and this is the view which is taken of the matter by the great majority of interpreters. The difference in the names, however, presents a difficulty which to not a few has appeared insuperable, and from which escape has been sought in various ways. Some, as Scaliger, Hottinger, Mill, believing that Ahasuerus and Artaxerxes in Ezra iv. 6, 7, mean Xerxes and Artaxerxes Longimanus, suppose also that Darius in chapters iv. 24, vi. 1, &c., means the successor of the latter, viz., Darius Nothus. But the identification of the Darius with the well-known Darius Hystaspes is sustained by so overwhelming evidence (see DARIUS), that this opinion may be at once and without hesitation rejected. Others, as Howes (see *Pictorial Bible* on Ezra iv.), Bley (*Jour. Sac. Literature*, July 1866), and many Germans,—as Kleinert, Schultz, Hengstenberg, Auberlen, Vaihinger, Bertheau, Keil, &c.,—believe that the paragraph, Ezra iv. 6–23, forms an interpolation or episode, in which the chronicler has summed up the attempts of the adversaries of Judah to hinder the building of the temple, as well as what they did for the obstructing of the building of the city under Xerxes and Artaxerxes, in order to bring together in a compendious way all their machinations against the Jews (see Keil, *ad loc.*) It is impossible, however, to reconcile this view satisfactorily with the language of the narrative, especially of ver. 24, the plain meaning of which is that the interruption in the work of the house of God caused by the decree of the king named Artaxerxes continued until, and hence was previous to, the second year of king Darius. Some German expositors, indeed, as Herzfeld (*Gesch. d. Volkes Isr.* i. 303), Merx, Schrader, &c., admit the irreconcilability, and, believing that the two kings in question were Xerxes and his son, maintain that the compiler of the book of Ezra was guilty of a mistake in referring the documents cited to the period preceding, instead of to the period subsequent to, the reign of Darius. But, apart from all questions about inspiration, this must be condemned as an illegitimate procedure. Our only original witness to the events connected with the return of the Jewish exiles is the book of Ezra, and it is not permissible to alter its testimony, or to set it aside as erroneous, because it presents some appearances of discrepancy with what is otherwise ascertained. It is to be added that the Apocryphal 1st Esdras, in the version which it gives of the same events, refers them and the king Artaxerxes to the period intervening between Cyrus and Darius (Esdras ii. 16–30, v. 72, 73), and that Josephus also in so far agrees that he assigns the events to the same period, though making no mention of Artaxerxes, and naming Cambyses as the king by whom the work at Jerusalem was hindered (*Ant. Jud.*, xi. 2).

Retaining, therefore, the more common view, and identifying the Ahasuerus and Artaxerxes of Ezra iv. with Cambyses and the pseudo-Smerdis, it remains to be considered if the difference in the names presents any insuperable, or even any serious, objection. Confining the discussion to the subject of the present article (for the other name see AHASUERUS), it has been already abundantly evinced that Artaxerxes is a regal name, and was assumed by all who are certainly known to have borne it, in addition to their private and personal designation, on their accession to the regal power. There is no difficulty in supposing that the Magian Gomates, when, in the absence of Cambyses on his Egyptian expedition, he personated Bardiya or Smerdis, the younger son of Cyrus, and usurped the throne, assumed also, like the later usurper Bessus, this as his official name, under which, of course, the public decrees of his administration would be couched, and which would naturally be most current among those who, like the Jews, belonged to the foreign subjects of the Persian monarchy (*cf.* Tyrwhitt, *Esther and Ahasuerus*, p. 333). Nor are we destitute of express though somewhat obscure testimony to the fact. Two other names are found applied in the classical writers to the pseudo-Smerdis. He is called Tanyoxares by Xenophon (*Cyrop.*, viii. 7) and by Ctesias (*Pers.*, 8–13), and Oropastes by Justin (i. 9). The latter, as Ewald (*Gesch. Israels*, iv. p. 118) suggests, may well be supposed to be a corruption derived from Ortosastes, which is an exact reproduction of the Hebrew form of the name Artaxerxes (*cf.* the rendering Ἀρθασασθά in the LXX., Ezra iv. 7, &c.) In regard to this identification two additional and final remarks are to be made. On the one hand, it is unreasonable to allege, as Keil and others do, by way of objection, that the reign of the pseudo-Smerdis was too short (only seven months) to allow of representations being made to his court, and an answer returned in reference to affairs at Jerusalem. It is to be taken into account that the enemies of the Jews had begun their machinations in the time of his predecessor, and their agents were doubtless present in the Persian capital when the new king ascended the throne, ready to avail themselves of the new opportunity. On the other hand, all that is known of the policy of the usurper is in excellent harmony with the part ascribed to him by the sacred writer. Belonging to the Magian tribe, and ruling, probably, in the interest of Median as opposed to Persian supremacy, he naturally set himself to subvert the policy of Cyrus; and we have express and indisputable testimony, in the elaborate inscription at Behistun engraved by the authority of his successor Darius, that his procedure, especially in regard to religious interests, was of the nature of a revolution, which the son of Hystaspes glories in having arrested and reversed (*cf.* Rawlinson's *Anc. Monarchies*, iv. p. 397).

In the Sassanian dynasty there are three royal personages bearing the name now in question:—(1.) The founder of the dynasty is called Artaxerxes, or Ardeshir, surnamed Babegan, from the name of his father Babek. He was probably tributary king of Persia under the Parthian rule, and he revolted against Artabanus, king of Parthia, about 220 A.D. Artabanus was defeated and slain in a great battle in the plain of Hormuz, and Artaxerxes succeeded in establishing the ascendency of Persia, and his own position as independent sovereign in 226 A.D. (see Malcolm, *op. cit.* i. p. 89; Rawlinson, *Sixth Oriental Monarchy*, p. 365, *f.*) (2.) Another Artaxerxes, belonging to the dynasty of the Sassanides, reigned for four years, 381–385 A.D.; and (3.) immediately before the Mahometan conquest, an infant prince was raised to the throne by the same name, and nominally occupied it for five months, 629 A.D. For further details regarding these monarchs see PERSIA. (W. TU.)

ARTEDI, PETER, an eminent naturalist, was born in the province of Angermania, in Sweden, on the 22d February 1705. His parents were poor, but found means to give him a liberal education, and with this view sent him to the college of Hernosand. Intending to become a clergyman, he went, in 1724, to study theology at Upsal; but he turned his attention to medicine from the strong bent of his mind for the study of natural history, in which science he made rapid progress, and soon rose to considerable eminence, particularly in the department of ichthyology, the classification of which he remodelled upon philosophical principles. This arrangement afterwards became popular over Europe. In 1728 his celebrated countryman Linnæus arrived in Upsal, and a lasting friendship was formed between the two. In 1732 both left Upsal, Artedi for England, and Linnæus for Lapland; but before parting, they reciprocally bequeathed to each other their manuscripts and books in the event of death. In 1735, however, they met again at Leyden, where Artedi was introduced to Seba, and was employed in preparing for the press the third volume of that eminent naturalist's *Thesaurus*, which chiefly related to fishes. He intended, as soon as that work was finished, to return to his native country, and publish the results of his own labours; but as he was returning home from Seba's house on the evening of the 27th September 1735, the night being dark, he fell into the canal and was drowned. According to agreement, his manuscripts came into the hands of Linnæus, and his *Bibliotheca Ichthyologica* and *Philosophia Ichthyologica*, together with a life of the author, were published at Leyden in the year 1738.

ARTEMIDORUS, a native of Ephesus, flourished during the reign of Marcus Aurelius. He called himself The Daldian, from Daldis, or Daldis, a small town in Lydia, the birth-place of his mother, in order to distinguish himself from Artemidorus, the geographer, who was likewise a native of Ephesus. The work by which he is known, Ὀνειροκριτικά, the Interpretation of Dreams, is said to have been written by command of Apollo Mystes, who had granted to the author the power of divination. The treatise, which contains some valuable notices on ancient customs and modes of thought, is divided into five books: the first and second, addressed to Cassius Maximus, treat generally of divination by dreams; the third and fourth, addressed to his son, discuss some minor parts of the theory; and the fifth consists of a collection of prophetic dreams which had been realised. Artemidorus boasts of the trouble expended on this work; he read all the authors on the subject, travelled widely, and corresponded or conversed with all who had made dreams their study. He is also said to have written on Auguries and Chiromancy, but these treatises are not extant. The best editions of his work are those of Reiff, with notes, 2 vols. Leip. 1805, and of Hercher, Leip. 1864. There are several English translations of it.

ARTEMIS [DIANA], in *Greek Mythology*, twin sister of Apollo, but born a day before him, as it was said at Athens for the sake of explaining the fact of the 6th of each month being sacred to her, while the 7th was his day. It might seem, too, that their mother, Leto, had borne them in two different places, since the birth-place of Apollo was Delos, while that of his sister is called Ortygia. But the word Ortygia, meaning strictly, a "haunt of swallows," applies still to Delos, and may well have been a synonym for that island. In this, its original sense, it does not apply either to the island of Ortygia at Syracuse, or to the spot so named near Ephesus, which were the two principal competitors for the honour of having been the birth-place of the goddess. Besides, she slew Orion in Ortygia, and that incident is connected with the mythology of Delos. Consistently with her relation to Apollo, she was conceived as sharing his aspect and attributes, her occupations and even her beauty tending rather to what would be appropriate for males. Both were endowed with perpetual youth, and this, if it did not originally help to suggest the idea of their being twins, is consistent with a universal feeling as regards that relationship. Like him she is armed with bow and arrows, which, jointly with him, she used against offending mortals as in the case of the Niobides, or of Laodamia, and the wife of Eëtion (*Iliad*, vi. 205, 428), she slaying women—he, men. At other times, with no sign of anger, her arrows brought soft death, such as Penelope desired (*Odyssey*, xviii. 201, xx. 62, 80). But, unlike Apollo's, the bow in her hands was chiefly employed, as a borrowed weapon might be, for the amusement of the chase. And here a broad line must be drawn between two sides of her character. On the one hand she is a sister of Apollo, and shares several of his functions, even taking part on occasion in his favourite music and dance. But in this respect her actions seem sometimes forced, as if grafted upon her in comparatively later times, as indeed seems also her name = ἀρτεμής, "spotless," as applied to a virgin. On the other hand she had what appears to be a more primitive name, Oupis or Opis, and a wide variety of functions, which are not only obviously suggested by the real and supposed influence of the moon on nature, but also approximate often closely enough to the functions of Apollo to have led to the identification of the two deities as brother and sister. The name Opis is taken to refer to the light of the moon. With that luminary she was distinctly associated, but not as guiding its movement,—a task which devolved on Selene (Luna), just as the course of the sun was directed by Helios, not by Apollo. To regard the goddess of the moon as sister of the god of the sun was natural, but it was an observation of a secondary kind, and founded only on the appearance and movement of those orbs. Primitive observations would refer to the sensations immediately awakened by the moonlight. In general terms Artemis, the moon goddess, was styled φωσφόρος or σελασφόρος, and carried, besides bow and arrows, a torch, here only with the idea of spreading light, and not as when, under the name of *hegemone*, she carried a torch to light the way for travellers, as in the typical instance of Demeter searching for Persephone. At Athens she had an annual festival, *Munychia*, on the 16th of April, for which cakes were made in the form of a full moon stuck over with lights. But, in particular, the spread of vegetation from the dew under a peaceful moonlight was ascribed to her influence. Her presence was felt near springs, streams, bays, on the sea, and in marshy places, whence she bore the titles of ποταμία, λιμναία, λιμνᾶτις. In lifting the veil of night she revealed to the imagination the world of wild animals, among which she was an intrepid and unwearied huntress, and over which she exercised the care of a goddess. Her favourite animal was the deer, whence she obtained in Olympia and Elis the title of ἐλαφία or ἐλαφιαία. Because Agamemnon had killed a deer sacred to her she detained the Greek fleet in Aulis, and required the sacrifice of his daughter Iphigenia. But while deer, goats, rams, and wild animals were generally regarded as dependent on her control, certain animals were specially associated with her in particular districts of Greece, as was the wild boar in Ætolia and elsewhere, and the bear in Arcadia, and in her worship as Artemis Brauronia, and Munychia at Athens. When a wild boar appeared ravaging a district, as did the Calydonian boar, it was sent by Artemis in anger. The boar, however, was not an instrument of her moods, but rather, it would seem, a symbol of the awakening every spring of the hunting season after the sleep of winter. "Bears" (ἄρκτοι) was the name sometimes applied at Athens to young girls who there, as throughout the rest of Greece, were under her special protection, in token of which it was usual for them to dedicate to her a lock of hair, a trinket, or some plaything. Boys also were under her care. With the symbol of a bear she was worshipped among the Arcadians, or "bear people," who claimed her as the primeval mother of their race, till, through the increasing prominence of her virginal character, that honour devolved upon Callisto, whose name is an obvious variation of καλλίστη, the title of Artemis, and her transformation into a bear an invention for the purpose. Arcadia was her chief hunting-ground, and more numerous were her sanctuaries there than elsewhere in Greece. As *Artemis agrotera*, a title under which she was worshipped in Attica, she was conceived not only as goddess of the chase, but also as in some way providing the wild impetus with which men rush into battle. Hence the 500 goats annually sacrificed at Athens, to commemorate the battle of Marathon, were sacrificed to her. It was customary with the Spartans to sacrifice a goat before closing with an enemy (Xenophon, *Hellen.*, iv. 2, 20). Possibly, also, the curious dance with which the maidens of Caryae (Caryatides), in the valley of the Eurotas, celebrated her festival had reference to her part in war. Her care over children was recognised in Laconia and Messenia under the name of κορυθαλία, to whose temple, by the stream Tiasa, nurses brought their charges at the festival of the Tithenidia, *i.e.*, festival of nurses. As λοχία or λοχεία she divided the worship of Ilithyia by her helping presence at childbirth. With marriage her care almost ceased, and hence it has been supposed that the dresses which women dedicated to her were such as they had worn as virgins, and were intended to express piety for her past protection. In reference to this, apparently, she was styled χιτώνη or χιτωνία. Youth, innocence, modesty, and a good name were thought to find high favour with her, and as an illustration of this was often told, in works of art and in the tragedies of Sophocles and Euripides, the story of Hippolytus. Her own purity was unsullied (ἁγνή, Æschylus, *Agamem.*, 135; αἰὲν ἀδμήτα, Sophocles, *Electr.*, 1239). Actæon, the huntsman, she caused to be devoured by his own hounds, because he had seen her bathing. She slew Orion because of his pressing advances to Aurora. She transformed Daphne into a laurel to preserve her from pursuit. Meadows in their spring verdure and flowers, fields with the seeds springing, and the gay seasons of rural life, gave occasion for thoughts of her overseeing care. She was hailed by rustic choruses, all manner of rejoicings, and, in particular, on a hill at the back of Mount Taygetus with songs known as καλαβοίδια. In Arcadia she was called *hymnia*. At the mouth of the Alpheus she was worshipped as Ἀλφειωνία or Ἀλφειοῦσα, the common belief being enlivened with the story of how she defeated the god of that river in his passion for her nymph Arethusa, by leading the spring Arethusa underground away to the island of Ortygia at Syracuse.

So far the various phases of her character are such as were more or less generally accepted in the times of literature and art. But there had also survived certain peculiarities in her worship from apparently very early times, though the fact of their being found only in certain localities renders it impossible to know whether they had been originally only local peculiarities or universally admitted. Of this kind was the Tauric Artemis, peculiar at first to the Crimea and the shores of the Black Sea. From the Crimea, Orestes, it was said, brought the ancient image of the goddess to Sparta, and with it her worship, the chief characteristic of which was the sacrifice of human beings which it required. At Sparta these sacrifices were afterwards commuted by Lycurgus for the ceremony of flogging youths at her altar, but not till this barbarous phase of her worship had spread to several places in Greece, Asia Minor, and Italy. Her title at Sparta was *Orthia* or *Orthosia*. Again, originally peculiar to Crete was *Artemis Britomartis*, or *Dictynna*, the latter name being interpreted by the legend that Minos had loved and pursued her till she leapt into the sea, and was saved by being caught in a fisherman's net. In this character she was chiefly the goddess of seafarers, and as such was widely worshipped on the islands and coasts of the Mediterranean. But nowhere was the worship of Artemis so non-Hellenic in character as among the Greeks at Ephesus. It would seem as if the Greek colonists there had found among the native Carians and Leleges a form of the moon goddess, which, though widely different from their own, had the advantage of an image that had fallen from heaven (*diopetes*), and an established hold on the people with whom the colonists had to deal. Like theirs she was a goddess with power over wild animals, and identified with their productivity, as appears from her being represented with many breasts,—a characteristic of animals, and not necessarily to be understood as expressing her interest in maternity in the usual sense, which would have been strongly opposed to the Greek feeling towards their virgin goddess. Her worship was surrounded by hierodulæ and eunuchs. She was the goddess of the warlike Amazons, whose fondness of the chase presented another point of contact between the Asiatic and the Greek goddess. But however much of the Greek element may in time have become grafted upon her, Diana of Ephesus was only in rare instances accepted by the Greeks outside of Asia Minor. The wealth and splendour of the temple made Ephesus a powerful attraction for devotees in the neighbourhood. A figure of her similar to that at Ephesus existed near Magnesia on the Meander, where from the name of the spot she was called Λευκοφρυηνή.

The usual figure of the Ephesian Artemis, as preserved in works of art, is in the form of a female with many breasts, from the waist to the feet resembling a pillar, narrowing downwards, and sculptured all round with rows of animals. In archaic works, as on the chest of Cypselus of Corinth, she appeared winged, and holding a lion with each hand. As to the original image, believed to have fallen from heaven, it is not impossible that it had been made to take the place of a meteorite. But the Greek Artemis was usually represented as a huntress with bow and quiver, in face very like Apollo, her drapery flowing to her feet, or, more frequently, girt high for speed. She is accompanied often by a deer or a dog. Perhaps the finest existing statue of her is the Diana of Versailles On the coins of Arcadia, Ætolia, Crete, and Sicily, are to be seen varied and beautiful representations of her head as conceived by the Greek artists in the best times. (A. S. M.)

ARTEMISIA, daughter of Lygdamis, succeeded her husband in the kingdom of Halicarnassus, which was a dependency of the Persian empire. She took part in person in the expedition of Xerxes against the Greeks, and fitted out five ships, with which she distinguished herself in the sea-fight near Salamis, 480 B.C. When closely pursued by the Athenians she escaped by the stratagem of attacking one of the Persian vessels, whereupon the Athenians concluded that she was an ally, and gave up the pursuit. By her advice Xerxes did not attempt another battle, but at once retired from Greece. A story of her, in all probability entirely without foundation, is preserved by Photius. She is said to have loved a young man named Dardanus, of Abydos, and, enraged at his neglect of her, to have put out his eyes while he was asleep. The gods, as a punishment for this, ordered her, by an oracle, to take the famous but rather mythical *lover's leap* from the Leucadian promontory.

ARTEMISIA, the sister and wife of Mausolus, king of Caria, immortalised herself by the honours which she paid to the memory of her husband. She built for him, in Halicarnassus, a very magnificent tomb, called the *Mausoleum*, which was one of the seven wonders of the world, and from which the name of Mausoleum was afterwards given to all tombs remarkable for their grandeur; but she died of regret and sorrow before it was finished. She appointed panegyrics to be made in honour of him, and proposed prizes of great value for the best oratorical and tragic compositions. She also erected a monument, or trophy, in Rhodes to commemorate her conquest of that island. When the Rhodians regained their freedom they built round this trophy so as to render it inaccessible, whence it was known as the ἄβατον. She died about 350 B.C.

ARTESIAN WELLS, the name applied to water-springs rising above the surface of the ground by natural hydrostatic pressure, on boring a small hole down through a series of strata to a water-carrying bed enclosed between two impervious layers. In Europe this mode of well-boring was first practised in the French province of Artois, whence the name Artesian is derived. At Aire, in that province, there is a well from which the water has continued steadily to flow to a height of 11 feet above the ground for more than a century; and there is, within the old Carthusian convent at Lillers, another which dates from the 12th century, and which still flows. But unmistakable traces of much more ancient bored springs appear in Lombardy, in Asia Minor, in Persia, in China, in Egypt, in Algeria, and even in the great desert of Sahara.

In ordinary wells the water does not rise, but remains at the bottom of the trough dug for it in the soil, and to raise it we must use special apparatus or pumps. In Artesian wells, on the other hand, the water rises from a considerable depth to the surface of the ground, and usually spouts up to a greater or less height above it. The theoretical explanation of the phenomenon is easily understood.

The secondary and tertiary geological formations, such as those underneath London and Paris, often present the appearance of immense basins, the boundary or rim of the basin having been formed by an upheaval of the subjacent strata. In these formations it often happens that a porous stratum, consisting of sand, sandstone, chalk, or other calcareous matter, is included between two impermeable layers of clay, so as to form a flat porous U tube, continuous from side to side of the valley, the outcrop on the surrounding hills forming the mouth of the tube. The rain filtering down through the porous layer to the bottom of the basin forms there a subterranean pool, which with the liquid or semi-liquid column pressing upon it constitutes a sort of huge natural hydrostatic bellows. Sometimes the pressure on the superincumbent crust is so great as to cause an upheaval or disturbance of the valley, and there can be little doubt that many earthquakes, that are manifestly not of volcanic origin, are due to this simple cause.

It is obvious, then, that when a hole is bored down through the upper impermeable layer to the surface of the lake, the water will be forced up by the natural law of water seeking its level, to a height above the surface of the valley greater or less according to the elevation of the level in the feeding column, thus forming a natural fountain on precisely the same principle as that of most artificial fountains, where the water supply comes from a considerable height above the jet.

In the Tertiary formations, the porous layers are not so thick as in the Secondary, and consequently the occurrence of underground lakes is not on so grand a scale, but there being a more frequent alternation of these sandy beds, we find a greater number of them, and often a series of natural fountains may be obtained in the same valley, proceeding from water-bearing strata at different depths, and rising to different heights.

It does not follow that all the essentials for an Artesian well are present, though two impermeable strata with a porous one between may crop out round a basin. There must be, in the first place, *continuity* of the permeable bed for the uninterrupted passage of the water; and there must be, on the other hand, no flaw or breach in either of the confining layers by which the water might escape. To one or other of these causes is due the failure of many attempts to find Artesian wells where from appearances they might be expected. It has occasionally happened that on deepening the bore, with the hope of increasing the flow of water, it has ceased altogether, doubtless from the lower confining layer being pierced, and the water allowed to escape by another outlet. The subterranean pool is frequently of small extent, and of the nature of a channel rather than of a broad sheet of water; and the existence of one spring is no guarantee that another will be found by merely boring to the same depth in its neighbourhood. Several such failures are recorded by Arago in his notices on Artesian wells in the *Annuaire du Bur. des Long.* (1835, &c.), and referred by him to the circulation of the subterranean waters in irregular trenches between impermeable masses. The preliminary theoretical determination of the existence of these Artesian conditions is in itself a difficult matter, and can be arrived at only by a thorough acquaintance with the geological disposition of the district. Still more difficult, as can readily be imagined, is the practical execution of the boring of a hole of a few inches diameter to the depth of hundreds of feet. The keeping of the bore quite vertical, the ready elevation of the loosened rubbish, the prevention of the breakage of the boring rods at great depths, are some of the difficulties that beset the operation, and have tried the ingenuity of engineers.

The mechanical appliances employed in boring deep wells are not essentially different from those used in the sinking of mining shafts; and it may be remarked that the expense and tediousness of Artesian boring at the beginning of this century are to be ascribed not so much to the want of steam engines, as to the awkward mode of using the boring tool. In the old method a continuous boring bar was made use of, the steel boring tool or chisel being fixed to iron rods, which were screwed together in lengths of 10 to 15 feet. This, with a strong cross handle at the top, formed a sort of large gimlet, and was turned by two men, the tool being raised and suddenly dropped, as required, by a third man at the end of a lever, which was connected by a rope or chain with the gimlet-head. Most of the accidents, which formerly rendered well-sinking a hazardous task, were due to breakages of the borer or boring bar by the sudden fall which it was necessary to give the too in pecking through a hard stratum. The modern mode of boring is but an adaptation of steam power to a simple method practised for ages by the Chinese. They bore their deep wells by a steel head worked up and down by means of a cord suspended from a lever—a wooden pipe being used to guide the borer and keep the hole perfectly vertical. Free falling tools, worked by steam power, are now employed when bore-holes of large diameter have to be executed, the weight of the tool giving sufficient percussion to pierce the hardest rock. In the enormous Artesian boring, of $5\frac{1}{2}$ feet diameter, begun, in 1866, at La Chapelle, in Paris, a boring tool of about 4 tons weight was employed. It was raised by steam power, and allowed to fall freely from twenty to twenty-five times a minute, a twist of $\frac{1}{15}$th of a turn being given after each stroke. (See *Engineering*, vol. viii. pp 401, 413.) The borer is withdrawn at intervals, and the rubbish removed by means of a cylindrical augur with a valve at the bottom. Permanent pipes of cast or wrought iron must be fixed in the bore-hole to keep it open; and if the operations are through clay or sand, the pipes must follow the progress of the chisel as closely as possible.

One of the most remarkable examples of the patience and skill required to surmount the difficulties of deep boring is the Artesian well at Grenelle, in the vicinity of Paris. The operation of boring extended from 1834 to 1841; after a depth of 1254 feet had been reached (May 1837), a length of 270 feet of the boring rods suddenly broke off and fell to the bottom of the hole, and nearly fifteen months' constant labour was required to pick it up again. Discouraged by the delay, the French Government was to have abandoned the project after a depth of 1500 feet had been reached without any satisfactory result; but the urgent representations of Arago prevailed on them to prosecute the work And it was fortunate, for an additional depth of about 300 feet proved the correctness of Arago's theory. On the 26th February 1841, at a depth of 1798 feet, the boring rods suddenly sank a few yards. The subterranean water-bearing stratum had been reached, and within a few hours a vast column of water spouted up at the rate of 600 gallons per minute, and at a temperature of nearly 82° Fahr., furnishing a valuable source of supply for a suburb of Paris where it was greatly wanted. Prior to this no Artesian boring had reached even 1000 feet; and that of Grenelle was the deepest executed till the completion (12th August 1850) of the salt-spring at Kissingen, in Bavaria, which throws up a column of water to the height of 58 feet from a depth of $1878\frac{1}{2}$ feet. The most remarkable feature of this spring is that the projecting force is due, not to hydrostatic pressure, but to that of carbonic acid gas generated at the junction of the gypsum with the magnesian limestone, about 1680 feet down. Modern mechanical improvements have enabled engineers to exceed these Artesian dimensions considerably, and at a greatly diminished cost. The well at Passy, near Paris, which is supplied from the same water-bearing stratum as that of Grenelle, was bored by the Saxon engineer Kind in a very short time, having been begun on 15th September 1855, and carried to a depth of over 1700 feet by March 1857. Its total depth is now about 1923 feet, with the enormous diameter of 2 feet 4 inches at the bottom; and it throws up a continuous stream of water at the rate of 5,582,000 gallons per day to a height of 54 feet above the ground. Among other deep wells sunk in the Paris basin subsequently to those of Grenelle and Passy, the following may be mentioned. A gigantic bore, 5 feet 7 inches in diameter, was begun in January 1866 at La Chapelle, and by November 1869 had reached a depth of 1811 feet, the intention of the engineers being to extend it to a depth of 2950 feet. The mechanical processes employed are detailed in pp. 401 and 413 of vol. viii. (1869)

of *Engineering*. A bore of 19 inches diameter was carried down to a depth of 1570 feet in about two and a half years (1864–7), for the purpose of obtaining a water supply for the sugar refinery of M. Say in Paris; and the same engineer who executed this work (M. Dru), began in 1866 an Artesian boring of the huge diameter of 6½ feet at the part of Paris named *Butte aux Cailles*, to be carried down to a depth of 2600 to 2900 feet. (See *Engineering*, vol. iii. p. 605.) Besides these monster wells, there are in the Paris basin a great many others, varying from 300 to 400 feet in depth, and from 2 to 8 inches in the diameter of the bore-hole.

The Tertiary chalk strata over which London stands have been riddled with Artesian borings for the sake of pure water supply. The source of the New River (which was opened in 1613) is one of the chalk springs, at Chadwell, near Ware; this alone yields London a twenty-fourth part of its water supply, some 4½ million gallons a day. Many of the large London breweries obtain the water employed in the manufacture of their beer from Artesian wells over 300 feet deep. The Kentish Town water-works have a well 900 feet deep, which penetrates the chalk bed some 580 feet. Artesian wells also supply water to the Bank of England, the fountains at Trafalgar Square, the Mint, Pentonville Prison, Colney Hatch Asylum, Shoreditch Workhouse, the North Western Railway Station, Holloway Prison, &c. On the duke of Northumberland's property at Sion House there is a chalk well which descends 620 feet, and spouts the water up about 4 feet above the surface. At Merton in Surrey, at Brighton, at Southampton, all along the east coast of Lincolnshire, and in the low district between the chalk wolds near Louth and the Wash, Artesian borings have long been known, and go by the name of *blow-wells* among the people of the district. It is worthy of notice that the general level to which the water rises in the London district has been very sensibly lowered by the immense number of perforations that have been made; and in several wells where the water formerly rose to the surface, it now stands considerably below it, and requires to be pumped up.

None of the Artesian borings in England approach the depths frequent on the Continent and in America. The average depth of the water-bearing stratum around Paris is six times that of the London chalk beds; and in some parts of Germany and of America, wells have been sunk to even double the depth of the Parisian wells of Grenelle and Passy. At Chicago there are two wells, one 700 feet and the other 1000 feet deep, with a diameter of 5 inches, which supply the city with 800,000 gallons of water daily. At the town of St Louis, in the State of Missouri, an Artesian boring was carried down for 3147 feet, but as only brine was obtained, it was ordered by Government to be stopped in September 1868, when the depth was approaching three-quarters of a mile. The deepest boring in the world is at Sperenberg, twenty miles from Berlin, having been sunk for the purpose of obtaining a supply of rock salt. A bore-hole of 16 feet diameter was carried down to the depth of 280 feet, where the salt bed began; after a further descent of 680 feet was attained, the bore was reduced to 13 inches diameter, and then continued till the extraordinary depth of 4194 feet was reached, without having pierced through the salt deposit, which has thus the enormous thickness of at least 3907 feet.

The following are some of the other most important Artesian sinkings that have been made. At Louisville, in Kentucky, a bore of 3 inches was carried to a depth of 2086 feet between April 1857 and the summer of 1858, when a supply of water almost as plentiful as that of Grenelle was obtained. At Charleston, South Carolina, there is a well 1250 feet deep, which was begun in 1848, and which discharges water some 10 feet above the surface at the rate of 1200 gallons an hour. In 1858 a well at Neusalwerk, near Minden, had reached the depth of 2288 feet. At Bourne, Lincolnshire, there is a well 95 feet deep, which yields over half a million gallons of water per day, the pressure being sufficient to supply the town and force the water to the tops of the highest houses. There is one, on the property of the Continental Hotel, in Philadelphia, over 200 feet deep, and 8 inches in diameter, which yields 50,000 gallons a day. Two Artesian wells at Croydon supply a million gallons of water per day; and Brighton draws over a million gallons from Artesian sinkings. There is a well at Bages, near Perpignan, which gives 330 gallons per minute; and one at Tours, which jets about 6 feet above ground, and gives 237 gallons per minute.

The boring of wells in the great desert of Sahara is a very ancient industry; and some oases are supplied with water wholly from Artesian wells. The average depth of these is from 160 to 200 feet, and the upper strata have only to be pierced to give a constant stream. With their primitive methods of boring, the Arabs often labour for years before they reach the wished-for pool; and with only palm wood as a casing, they have great difficulty in keeping the bore-hole from closing up by the drifting of the sand, and they require to scour them out periodically. Since 1858 an immense number of perforations have been made by French engineers, and the fertilising effect upon the sandy desert plains is already making itself apparent. Villages are built and palm trees are growing where formerly there was but waste and solitude. (See *Geological Magazine*, vol. i. p. 31.) The importance of deep wells in such cases cannot be over-estimated.

Artesian wells have been made to supply warm water, for keeping hospitals, &c., at a constant temperature. Invariably the temperature of water from great depths is higher than that at the surface, this being due to some unknown source of heat in the interior of the globe. The temperature of the water in the well at Grenelle is 82° Fahr., and that of Passy the same, showing that they have a common source. Kissingen well has a temperature of 66° Fahr., that of St Louis one of 73°·4 Fahr., that of Louisville 76½° Fahr., and that of Charleston 87° Fahr. The average rate of increase of temperature is 1° for a descent of from 40 to 55 feet. In Würtemberg the water of Artesian wells is employed to maintain in large manufactories a constant temperature of 47° when it is freezing outside. Artesian waters have also been employed to reduce the extreme variations of cold in fish-ponds, which are so fatal to their finny inhabitants.

ARTEVELDE, Jacob van, a celebrated Flemish popular leader in the 14th century, was a brewer in Ghent. His enormous wealth, great eloquence, and general talent for administration, easily made him the most prominent and powerful man on the side of the citizens in their struggle against the encroachments of Count Louis of Flanders. The people of Ghent gave him the command of their forces, and he banished from the town all the nobles and adherents of the count. In 1335 he made a commercial treaty with Edward III. of England, and with the aid of some English troops expelled Louis from Flanders. Ten years later, in 1345, after having persuaded Edward to assume the title of king of France, and induced the Flemings to support the claim, he thought to cement the alliance by making the Black Prince count of Flanders. This proposal was badly received by a large body of the people of Ghent, who were dissatisfied with their leader's somewhat arbitrary government. A popular tumult broke out with its usual impulsiveness, and Artevelde was slain.

ARTEVELDE, PHILIP VAN, son of the above, lived in retirement till 1381. Some years before that date enmity had again arisen between Count Louis of Flanders and the somewhat turbulent citizens of Ghent, who, under one Hyons, had expelled the count's adherents, plundered his house, and slain several of his officers. Hyons died in 1379, and in 1381 the citizens, under Peter van der Bosch (Dubois), were closely blockaded by the count. In this emergency Van der Bosch proposed that the son of the great Artevelde should be invited to take the direction of affairs. Philip accepted, at once entered on public life, and by some strong measures secured his power. The inhabitants of Bruges had at this time allied themselves with the count, and Artevelde resolved to punish them. He led out his forces quietly, and utterly defeated the army of the count, who escaped with difficulty. Bruges was plundered, and submitted to Artevelde. Next year the French, taking up the cause of Louis, invaded Flanders, and at Rosbecque completely routed the forces of Ghent. Many thousands were slain, and among them Artevelde himself. The brief but stirring life of this popular leader is admirably treated in Sir Henry Taylor's drama, *Philip van Artevelde.*

ARTHROPODA. The Aristotelian distinction of *Malacostraca*, or Crustaceans, and *Entoma*, or Insects, has been referred to by Agassiz as in reality more precise than Linnæus's last classification (1766), in which his Crustaceans form part of the Apterous group of insects. But whereas the Greek naturalist recognised the notchings which indicate annuli, *somites*, or body-rings, in *Coleoptera* and the other groups to which the class-name Insect is now restricted, and in Worms, under which he comprehended insect larvæ, several true Annelids, and intestinal worms (Scolecida), he failed to appreciate this as a feature common to the *Malacostraca* or *Scleroderma*, which he named on account of the character of their integument. Linnæus, on the other hand, saw that annulation was the most prominent common feature, and his *Insecta*, therefore, were a good natural group so long as embryology could throw no light on the affinities of the Cirripeds and parasitic Crustaceans—these two groups forming, together with the intestinal worms, molluscs, zoophytes, and lithophytes, the class *Vermes*. Cuvier (1829) includes in the third branch of his scheme, *Animalia articulata*, Annelids, Crustaceans, Arachnids, and Insects (the Myriapods being an order of this class). Latreille (1796) proposed a scheme in which the orders of the Insects (as now restricted) formed equivalent groups with the Crustaceans, Arachnids, and Myriapods, which now first appear as a distinct group, though still united with a section of the Crustaceans. Latreille further, in 1801, recognised the Cirripeds as intermediate between his *Insecta* and the Molluscs. Lamarck gave the value of classes to the Insects, the Arachnids (including therein the *Thysanura* and *Myriapoda*), the Crustaceans, and the Cirripeds. But he has no province answering to the Cuvierian *Articulata*, since these orders are, with Annelids, Conchifers (= Lamellibranchs), and Molluscs (= *Odontophora*), members of the "sensitive animals," the Lernæans and other parasitic Crustaceans being an order of the *Vermes*, and therefore apathetic animals. De Blainville, still relying chiefly on external form, recognises four types in the sub-kingdom of the bilateral animals:—(*Artiomorpha* or *Artiozoaria*), of which the first is *Osteozoaria* (Vertebrates). The second *Entomozoaria* (Articulates) includes: Class 1. HEXAPODA, *Insecta proprie sic dicta*; 2. OCTOPODA, *Arachnida*; 3. DECAPODA, *Crustacea decapoda and Limulus*; 4. HETEROPODA, *Squilla, Entomostraca, Epizoa*; 5. TETRADECAPODA, *Amphipoda and Isopoda*, 6. MYRIAPODA; 7. CHÆTOPODA, *Annelides*; 8. APODA, *Hirudo, Cestoidea, Ascaris.* The third type, *Malentozoaria*, is intermediate between the Articulates and Molluscs, and embraces two classes: *Nematopoda*, Cirripeds; and *Polyplaxiphora*, the Chitons. The classification of which this forms a part is a compromise between the method of Cuvier, based on the recognition of distinct plans, and that of Ehrenberg, who sketched each group as departing from the common plan of the animal kingdom only by excess of development in one or other direction. The *Articulata*, viz., *Insecta*, *Arachnoidea*, *Crustacea* (the Cirripeds and Epizoa being included), *Annulata*, and *Somatotoma* (the two latter making up all that are now known as Annelids), he distinguished from Molluscs by the isolation of their ganglia and their succession, those of the Molluscs being dispersed. Owen's *Homogangliata*, as equivalent to *Articulata*, is the expression of the same difference: his *Insecta* embrace two sub-orders, *Myriapoda* and *Hexapoda*, and the *Annellata* are placed between the Epizoa and Cirripeds. Milne-Edwards (1855) divides the *Entomozoaria* or *Annellata* into two groups,—(1.) *Arthropoda*, including Insects, Myriapods, Arachnids, and Crustaceans; and (2.) *Vermes*, including Annelids, Helminths, Turbellarians, Cestodes, and Rotifers. Siebold and Stannius (1845) made the Arthropods a primary division co-ordinate with *Vermes*, and united the Myriapods with the Crustaceans. Leuckart's *Arthropoda* comprise two classes,—*Crustacea* and *Insecta*; the latter combining the orders, *Myriapoda*, *Arachnida*, and *Hexapoda*. Fitzinger's *Arthrozoa*, or eminently motor animals, Crustaceans, Arachnoids, and Insects, contrast with the *Dermatozoa* or Molluscs, which are eminently sensitive. Von Baer's *Articulata* correspond to the Cuvierian group under the same designation, and like it represent a type of organisation, the longitudinal or bilaterally symmetrical, the organs being arranged with reference to the axial alimentary canal. The embryological system of Van Beneden (1855) rests upon the position of the vitellus relatively to the surface of the embryo, the Articulates being designated by him *Epicotyledones* or *Epivitellians*, the vitellus being received into the embryo on the dorsal or upper surface, while the vertebrates receive the yelk on the ventral or lower surface, and are therefore *Hypocotyledones* or *Hypovitellians*. As will be pointed out afterwards, this nomenclature is unfortunate, since the surfaces thus contrasted are identical, both being the hæmal aspects of the body. It may further be remarked that the term *Articulata* is manifestly one which should be abandoned, since it is made to represent very different things, being used by Cuvier, Ehrenberg, and Owen to include the Annelids,—by Van Beneden, Vogt, and some more recent writers, to their exclusion. Neither is *Arthrozoa*, the Greek equivalent of *Articulata*, more commendable, Burmeister and Fitzinger using it with the same difference. But *Arthropoda* has varied only in the rank assigned to it, not in the area it represents, thus Milne-Edwards makes it a sub-division of the *Annellata*, Van Beneden, Siebold and Stannius, and Leuckart, a primary division of the animal kingdom. But as a general designation for those animals which are made up of nearly equivalent somatomes or somites is needed, Macleay's term *Annulosa* is, perhaps, the best, since it has never been used for two incommensurate groups. Leach, and later (1825) Latreille, proposed *Condylopoda* as the name of the group for which *Arthropoda* was afterwards devised. Custom has overborne the rule of priority, and the later is now the more common name. The classifications hitherto mentioned rest solely on an anatomical basis, those of Von Baer and Van Beneden dealing only with the observed facts of development. Haeckel, applying all that was known of embryology to the construction of the pedigree of the groups, made (1866) the *Articulata* one of the five great trunks of the genealogical tree. The Articulate phylum embraced the Infusoria and intestinal worms, as well as the Annelids, along with the *Arthropoda* as restricted above. The *Arthropoda* further formed two groups :—*Carides*, the branchiate Arthropods or Crustaceans; and *Tracheata*, the Arachnids, Myriapods, and Insects, which breathe by tracheæ. The term Articulate disappears from Haeckel's latest classification, in which a redistribution of the phyla is set forth. From assumed ancestors destitute of body-cavity (*Acœlomi*) descend those *Vermes* with body-cavity, of whose plan *Echinodermata*, *Arthropoda*, *Mollusca*, and *Vertebrata* show special modifications. In 1870 Gegenbaur gave a general table, in which the *Vermes* included *Tunicata* and *Annulata*. The former led towards the *Mollusca;* the latter was the starting point of *Arthropoda*, *Vertebrata*, and *Echinodermata;* of the Arthropods there are four classes,—Crustaceans, Arachnids, Myriapods, and Insects. Amidst all the varying opinions as to the value of the group, the importance of the limb-structure has been recognised since Latreille dwelt upon the articulations by which the parts of these appendages are connected.

The *Arthropoda* agree in the characteristic already mentioned, the articulations of their limbs, whence the class-name is derived. The body presents various degrees of complexity. In the caterpillar, the *metamera*, *somites*, *somatomes*, or *annuli*, owe their mobility to differences in thickness of the integument. In the Myriapods the numerous similar somites are flexed on each other by the overlap of the chitin-thickened portions of cuticle which protect the upper and lower surface of each division. The somites are more or less effaced in the abdomen of insects and spiders; head and thorax in crabs and spiders have their composite origin concealed. But the external signs of division of the body no longer correspond, as in Annelids, to the distribution of the internal organs, which, with a partial exception in the case of the nervous system, are now unities contributing to the well-being of the whole. Homonomy, the absence of segmentation, or the equivalence of the divisions of the body, among the Annelids, has been contrasted with the heteronomy, or segmentation of the arthropod body. The difference, however, is only one of degree, since both the cephalic and caudal extremities, at least of the higher Annelids, are true segments, *i.e.*, fused somites which, in addition to fusion, have undergone some amount of specialisation. In the four classes of Arthropods the head is a constant segment. It consists of præ-oral and post-oral somites, the ganglia of which are represented by the supra- and sub-œsophageal masses. The number of somites, as represented by appendages, is not the same in the four classes, and as the variation affects the præ-oral appendages supplied from the supra œsophageal ganglion the difference is of great importance. In the Crustaceans the somites of this segment are, according to Huxley,—

App.—	Eyes,	Antennæ,	Antennules,	Mandibles,	Maxillæ,	Maxillæ.
Som.—	1.	2.	3.	4.	5.	6.

The *Podophthalmata* present the eyes as modifications of processes identical with those which become ambulatory limbs. In the rest the eyes are sessile. In Myriapods, Arachnids, and Insects, the eyes are sessile, and the præ-oral appendages are reduced to one pair of antennæ, whose innervation is from the supra-œsophageal ganglion. Apart from the value to be assigned to descent in the search for homologies among these classes, it is a question of fact whether the eyes are præ-oral or lateral to the oral aperture. The cephalic lobes carry the organs of sight probably in the earliest types of development at the angle of bifurcation, the position of the single eye of Ostracods. In more complex forms the eyes appear more or less towards the outer margin of the lobes; and in insects where the cephalic arch is high, these organs may appear to correspond not to the most anterior, but to a posterior part of the cephalic sterna, just as sensory organs appear, the gustatory at the base of the outer, the auditory at the base of the inner antennæ in the higher Crustaceans. By shortening of the development process the change of position may be obscured, and the eyes, primitively belonging to the extremity of the embryonal body, may from the first appear connected with more posterior somites. The identification of homologous parts of the præ-oral region in the four classes rests on the opinion held as to the origin of the classes. If the Crustaceans are regarded as the stock of the Arthropods, the homologies must be recognisable. If, on the other hand, all four are divergencies from a common stock, then the absolute identity of the parts must hold a second place in comparison with a general conformity to the common plan. The identification of the eyes with a particular pair of appendages necessitates the assumption that these sense organs, when sessile, are so by non-development of their supports. The converse supposition is more admissible, that the eyes are supported on stalks as the result of an adaptive modification. Further, among the Crustaceans we find hints of the primitive composite character of the Arthropod. The auditory sacs of *Mysis* are at the caudal extremity of the body, the respiratory organs of Isopods are in the same position, and the genital orifices vary in different genera, and even in the sexes of the same species. Analogous (perhaps no more) is the distribution among Molluscs of the eye-spots which fringe the mantle of *Pecten*, are pedunculate in the snail, and, with the otolithic sacs, are in close proximity to the nerve centres of cuttlefishes. If this view is accepted, the close comparison of the limbs of Arthropods loses much of its importance, and it becomes more interesting to endeavour to trace the primitive form from which the divergences have occurred. Among Crustaceans the Nauplius is the earliest recognisable form,—"an unsegmented ovate body, a median frontal eye, and three pairs of natatory feet, of which the anterior are simple, and the other two biramose" (F. Müller). The third pair of appendages is replaced by the mandibles, the oval body is divided by a transverse fold, and the Nauplius head and tail thus marked off have the mid-body of the adult developed by intercalation between them. Appendages are developed before segmentation is indicated in the free living Nauplius; but in some this stage is overpassed in the egg, the evidence of its existence being the presence of a thin exuviated membrane which is not egg membrane, nor can it be termed amnion, without overstraining that term which is properly used in the higher vertebrate embryology. In Insects the vermiform stage is rapidly passed through, the priority of segmentation to the development of appendages being indicated in the *Trichoptera*, according to Zaddach, and in Aphis, according to Huxley. If we go to the Rotifers, there are in that group types which are comparable with the Nauplius of Crustaceans, and with the vermiform larvæ of Insects, as O. Schmidt and Lubbock (*Origin and Metamorphoses of Insects*) have shown. *Pedalion mira* (Hudson) has a very close resemblance to the Nauplius, *Lindia* to the vermiform grub of Dipterous insects. The resemblance is not impaired by the comparison suggested by Ray Lankester between the Molluscs and Rotifers. Huxley calls the Molluscs "little more than oligomerous modifications of the polychætous Annelids" (*Nature*, December 10, 1874); and in this article it is attempted to show what are the simplest forms presenting common features with the Arthropods. The hexapod Insect has been compared by Haeckel, F. Müller, and others to the Zoëæ of Malacostracous Crustaceans, a group in one member only of which, *Peneus*, has a Nauplius stage been detected. The Zoëa and the Insect possess alike three pairs of limbs for locomotion, and three for ingestion of food. The abdomen in both is without appendages, and the mandibles are without palps. Admitting the resemblances, there is a prior question to be settled in the case of Insects, Myriapods, and Arachnids. Are the temporary embryonal investments of these animals, the cellular and the structureless membranes, to be compared with the blastodermic moultings of Crustaceans, with that membrane whose presence in the Amphipods is accepted by some observers, as the last trace of the Nauplius stage? In the Acarids Claparède found the inner layer to invest the embryo after the outer gave way, and Metschnikoff recognises the deutovum in *Platygaster* also. The identification with the Nauplius is strongly denied by the last-named observer; but there is still room for further investigation, since embryologists of high reputation differ so entirely on the matter of fact, irrespective of phylogenetic theories. Should the identification be accepted, the Arthropods would, as a group, agree in having a Nauplius stage, different in detail in each class; the second, or Zoëa stage, would differ still more in each, and the homologies of the parts would thus become obscured in details, the identity of the general plan being clearly recognisable. All the Arthropods agree in having the terminal portion of the intestinal canal derived from the outer, the middle portion from the inner embryonic layer. Lastly, the Arthropods, in common with the Molluscs and Annelids, have their body-cavity, or perivisceral space, formed by the splitting of the mesoblast, or derivative layer formed between the outer and inner layer (epiblast and hypoblast, and ectoderm and endoderm). In Insects, in the higher Arachnids, and Crustaceans, yelk segmentation is partial; in Myriapods, and the lower Arachnids, and Crustaceans, it is total; but as in Insects, for example, the unsegmented yelk undergoes at a later period a division into polygonal masses, the difference, though of value in classification, is not of primary importance. The relation of the branchiate Arthropods, the Crustaceans, to the other three tracheate classes, has been discussed chiefly from a phylogenetic point of view. The priority of aquatic to terrestrial forms is assumed, and the derivation of the latter from the former is traced in various ways. The somites or metamera of the Arthropod retain, more than the nervous system which is derived from the epiblast, and still more than the alimentary canal and its appendages, the annulose characteristic that each represents a unit; each may, and many do, give rise to appendages originally similar, but afterwards modified for special functions. Hence the same limbs are tactile in Crustaceans, prehensile in Arachnids, ambulatory in some Crustaceans, accessories of mastication in others, locomotive in some, respiratory in others. In Insects the abdomen of the adult is destitute of appendages, but many larvæ are provided with tracheal gills, that is, external processes in which air-canals ramify, and in which a large quantity of blood is received within the cavity of the thin-walled dilatable process. These processes are destitute of external apertures, the tracheal system is in them closed. Such structures are found but rarely to co-exist with the open condition of this tracheal system. But *Pteronarcys*, one of the Orthopterous order, is remarkable for this conjunction, the branchial processes of the adult overhanging the stigmata of the tracheæ. Considerable variety exists in the position of the gills. The larvæ of *Perla* have three thoracic pairs of gills, and are terminal of the abdomen. In other cases they are confined to the abdomen. Now, it is to be noted that these gill projections are not at first tracheal; in *Chloea* the tracheæ appear after another moult, and they are then vibratile. Further, they are developed from the upper surface of the body. Now, in the Annelids the limbs are typically double pairs projected from the sides of the body, the parapodia consist of two branches, notopodium and neuropodium, and the gills when present are modifications of the notopodium. In the Crustaceans this bipartite condition is indicated by the exopodial and endopodial divisions of the limbs. In the adult insect this duplicity has disappeared, unless we recognise in the position of the gill tracheæ the equivalent of the branchiferous notopodium. Gegenbaur and Lubbock regard the wings as tracheal gills transferred from locomotive organs in water to locomotive functions in air. Gegenbaur thinks that the dropping off of the gills determines the opening of the tracheal system by the stigmata or pores. Further, he assigns to the closed tracheal system a function similar to that of the swim-bladder of fishes, structures primarily useful in flotation, subordinately respiratory in function.

Natural as may seem the assemblage included under *Arthropoda*, there is no group in which adaptive modifications have introduced so much diversity of anatomical and physiological relations. Metamorphoses, the changes of form which changes of external conditions have promoted, are met with of very various amount. The progress of the embryo from the first appearance of the blastoderm up to sexual maturity of the adult may be direct, without metamorphosis, or may be retarded by changes of form and habit, rendering the young animal capable of sustaining life under very various conditions. In any one of these stages, even in the adult, multiplication may be provided for by a process of budding, the bud from which the new form emerges being in essence undistinguishable from the ovum for whose further development impregnation is necessary. These metamorphoses are probably of late origin in the history of the group, their perpetuation being due to change in their surroundings. Their relations may be "falsified by the struggle for existence," the details of the developmental history of the family (phylogenesis) may be crowded into a short space in the development of the individual (Ontogenesis). The description of these variations belongs to the particular treatment of the Crustaceans, Myriapods, Arachnids, and Insects. (J. Y.)

ARTHUR, or ARTUS, a hero of the Welsh Tales, the Chronicles of Geoffrey of Monmouth, and the Romances of the Round Table. His exploits, even the most fabulous, passed with historians, before the days of historical criticism; subsequently a reaction led to the figure of Arthur being regarded as nothing but a Celtic myth. The truth, so far as it is possible to arrive at it, lies between these two extremes. There was a real Arthur, one of the last Celtic chiefs in Great Britain; but there is no single trait of his real character and exploits which legends, working according to laws to be presently discussed, have not remodelled and transfigured or disfigured; while the scarcity of documents makes it impossible to reconstruct a coherent historical picture. Thus the work of comparison between the historical and the legendary personages, such as has been performed for Charlemagne by MM. Gaston Paris and Léon Gautier, is impossible in the case of Arthur. We can only study the legend and analyse its elements.

There is an error, not so popular as it once was, which supposes that myths and legends are arbitrary creations, and does not recognise them as having an origin in regular causes, and therefore a rational history, before the period when they are crystallised into their final legendary form, or are merged in the current of a literature in that later and artificial stage when it disinters and refashions old materials. Before Arthur took his final French form in the Romances of the Round Table, he was a Celtic hero in the Breton, and more specifically still in the yet earlier Welsh, legends. And behind these is the original Arthur, of whom we must be content with such impressions as we can gather from his contemporaries, Myrdhinn and Lywar'ch.

Lywar'ch, a bard and king, born about 480, was one of the companions of the valiant chief, Urien of Reghed, in Cumberland, upon whose death he composed a pathetic lament. He survived the death of his twenty-four sons in the last struggles against the Saxon, and in his old age, banished and a cripple, he wrote from his hiding-place a mournful hymn on his own and his country's decay, in which lovers of the poetry of despair have admired this verse worthy of Job:—"See yonder leaf driven by the wind; woe for him who has the like lot! it is old, though born within the year." But the bard-king had only despaired after a life-long struggle, and in like manner the bard-prophet Myrdhinn had long sung in praise of peace before he went mad with grief, on the night of the battle of Arderidd, where the northern and southern Celts slaughtered each other to the profit of the Saxons. Before this fratricidal struggle (the beginning of the 6th century) Myrdhinn had cherished the dream of the resurrection of an ancient chief, whom he called Lemenitz:—

"My prophetic soul foretells it; discord shall reign among the British tribes until the federation which shall be formed by the chief of heroes, Lemenitz, when he comes back to the world. Like the dawn he will arise from his mysterious retreat."

By this chief of heroes, destined to bring back union, the bard meant his king and friend, Aurelianus Ambrosius, and after his death Arthur, his valiant successor, and Myrdhinn's own pupil. The battle of Arderidd came to dissipate the last of these illusions. One of the contending hosts consisted of northern Celts, bent upon imposing on all of their race yet unconquered in Great Britain the authority of Howell of Scotland, the brother of that Gildas who soon afterwards became a convert at once to Christianity and to Saxon interests. The other host, that of the southern Celts, was led by Aurelianus Ambrosius, whose favourite bard was Myrdhinn. After the final destruction of the Celtic power, the destiny of Myrdhinn is to reappear in legend with the Latinised name of Merlin. Aurelianus Ambrosius and Arthur, the two Celtic chiefs to whom the bard had been so loyal, undergo a like resurrection; but their lives and exploits are confounded, according to the accumulative method of legend, with each other and with those of Vortigern, king of Kent. The Arthur of the legend more than realises all the prophecies of Merlin; and these prophecies in the process of oral repetition, and in travelling further from the place and the time of their origin, themselves were altered to an ampler tenor. They underwent one great degree of change in crossing the Channel, and another and greater in passing from the soil and speech of Brittany into those of France. With the tenor of the prophecies grow the proportions of the hero. The poetic Arthur pacifies the Celts, quells the Saxons, and ends by establishing a reign of justice upon earth. It is a hard saying, but true, that the key to all this is a certain sentiment which is the mark of conquered races. The Celtic genius after its defeat in arms would have revenge in songs. What happened was this. The Celtic chief, Vortigern, summoned to his help the Saxon chief Hengist. Now, let it be noted that, in the annals of the Saxon kingdom of Kent, the fourth king in succession from Hengist is the Saxon Ethelbert. Turning to the legend, it will be found that the corresponding fourth king in succession from Vortigern is the British Arthur. For in legend the treachery of Vortigern must not be allowed to bear fruit, the Celts after many a struggle must be left conquerors. The honour of giving the last blow to the Saxon invasion in Kent, West Wales, and elsewhere, is assigned in the legend to Arthur. And why to Arthur? Because of the ancient prophecies of the resurrection of the fabled Lemenitz, with whom later times identified him, and above all, because the whole legendary structure hinged upon the impressive portraiture of Merlin, whose historical prototype had, in fact, been the devoted follower of the historical Arthur and Aurelianus Ambrosius. But this edifice of fable, under which the Celts strove to hide from themselves the real ruin of their race, was not built up in a day. The conquered people repeated and enlarged upon the prophecies of Merlin; and with these grew the figure of Arthur, enriched by every noble trait which could be borrowed from the stories of the bravest chief., and made to accord with the prophecies. Round the main personage soon revolved other ideal types, and little by little was founded the harmonious hierarchy of King Arthur and his knights, such as it now remains in romance, and such as never existed in reality. The tales were then carried into France, for just as in England the Irish bards were held in higher esteem than the Welsh, in France the Breton lays were preferred to the songs of the *trouvères*. While this work of infiltration was going on, Geoffrey of Monmouth set down, in 1130 and 1147, the Arthurian legend in his *Historia Britonum*, and, emboldened by the popularity of this work, published afterwards a poem entitled *Vita Merlini*, which lent the authority of Latin to the tissue of fabulous successes. Robert Wace translated the chain of legends into old French, and Richard de Borron added his *Saint Graal*, which serves in some sort as a theological preamble to the Romances of the Round Table. At that time the poems of the Carlovingian era had lost their hold on popular favour, as much from the unreality of their heroes,—*Charlemagne à la barbe florie*, *Roland*, and *La violente Blanchefleur*,—as because the dominant sentiment pervading these poems, as binding faith and loyalty between vassal and lord, had ceased to find an echo in the hearts and life of the people. An attempt was made to replace the Carlovingian Cycle by another formed from the various songs taught by Breton minstrels to *trouvères* and troubadours; for Charlemagne was substituted the far more poetical type of Arthur. *Languor*, *fatality*, *pleasure*, were all personified in Lancelot, Tristan, Gaurin, &c., and the Romances of the Round Table took the shape in which they now remain. Nevertheless, those who have traced the legend to its source, and for whom the ancient Celtic foundation is still visible, will regret in reading even the graceful paraphrases of Christian de Troyes, or the sweet and simple poems of Marie de France, their departure from the original types.

The recent discoveries of Messrs Owen Jones and Hersart de la Villemarqué in Welsh literature show us how much the romances lost in elevation of sentiment and depth of thought as they varied from the Celtic model. To give an example of this revarnishing and its effect in concealing the primitive foundation, we may cite Tristan, who, in the original legend, drinks the philtre to obtain by it all knowledge, and his madness and despair that ensue are the madness and despair of one fatally gifted with universal insight; whilst in the French romance the philtre becomes a vulgar love draught. This was only a preliminary step to the false sentiment of modern French *romanticists*, who have since, in their exaltation of the passions, dispensed with philtres altogether. In the same way Merlin, in the Welsh texts, is mad with grief on beholding a fratricidal war, and his madness, according to the old Celtic idea, endows him with the power of a seer and magician over all nature. In the romances his frenzy and magical power have no worthier cause than his love for Vivian.

The figure of Arthur, on the contrary, seems to gain in dignity by the migrations of the legend. In the Welsh tale of *Owain and Gherain* (Ivain et Erec, with Christian de Troyes), we see him, it is true, holding his court during

Easter and Pentecost at Caerleon on the Usk, but as a little exalted monarch, a *roi-bonhomme*, asleep on his throne, while the chiefs of his following relate at their ease all their adventures. Here we find preserved the idea of the individual independence of all the Celtic chiefs, whose king, only *primus inter pares*, must necessarily have been as little of a sovereign as possible. After the legend has passed into France Arthur becomes a sort of rival Charlemagne, holding supreme and boundless sway, though never as a real feudal emperor (they were tired of that in France), but rather as a Marcus Aurelius,—a monarch, half philosopher, ruling chiefly by his wisdom and subtlety, and still more a judge than a general over his people. The type is one which belongs essentially to the Celtic mind, more akin to the Greek than any other, and naturally as far removed from the Roman as from the Saxon turn of thought.

Among the writers of the 17th and 18th centuries the historical existence of Arthur was, with a few rare exceptions, denied, and the Arthurian legend regarded purely as an invention of the worthy chronicler, Geoffrey of Monmouth. Pinkerton bestows a moment's notice on "the king whose exploits fill all the poetry of the Middle Ages, and whose very existence is doubtful," and then passes on. The difficulty of establishing the filiation of Arthur perplexed Milton, who says, "As to Arthur, more renowned in songs and romances than in true stories, who he was, and whether any such reigned in Britain, has been doubted heretofore, and may again with good reason. No less is in doubt who was his father; and as we doubted of his parentage, so may we also of his puissance." Guinguené settled everything by the unwarranted explanation, that English romancers had invented an Arthur out of jealousy of the French Charlemagne. English writers of Guinguené's calibre in mythical science replied, that Arthur was a French invention of Richard or Elie de Borron, or of the Anglo-Norman Mapes, basing the assertion on an expression found in Geoffrey of Monmouth. Ampère, deficient here in his usual penetration, throws entire discredit on the good faith of Marie de France, who speaks of having seen and handled the original Celtic MS. Fauriel, and with him the other French *savans*, would fain have attributed the Arthurian legend to the troubadours rather than acknowledge its Welsh origin. He asked for the tests which have since been discovered by Mr Owen Jones and commented on by M. Hersart de la Villemarqué with perhaps indiscreet zeal. Sir Walter Scott's excellent historical instinct had already exhibited a part of the truth in his edition of Thomas of Ercildoune's Rhymes. We may now, therefore, venture on being more positive than Southey, and less sceptical than Mr Thomas Wright, the two modern editors of the translation which Sir Thomas Malory made in 1634 of the five Romances of the Round Table (he "compiled the booke oute of certaine bookes of Frensshe, and reduced it into Englysshe"), and we may follow almost step by step the development of the legend, and of the various Arthurs, from the British Arthur of history to the mythical Arthur of Cambrian and Breton tradition, and lastly to the French Arthur, the rival of Charlemagne.

We shall conclude by noticing the main features of the character of Arthur, and indicating their origin.

Historic Facts.—The general belief regarding Arthur has been that he was a leader of the Celtic tribes of the west of England against the Saxons. It is recorded that, about the middle of the 5th century, Kent, after suffering from famine and pestilence, was invaded by the Picts and Scots, while at the same time another struggle, longer and more keen, was taking place in West Britain against another Saxon invasion. The longer and braver resistance of the Western Celts is partly set down to the merit of their leaders, Aurelianus Ambrosius and Arthur. The men of Kent, however, after a vain appeal to Ælius, prefect of the Gauls, were induced by Vortigern, their most important chief, not only to make peace with the Saxons, but to invoke their aid against the Picts and Scots. Hengist was appealed to, and the looked-for Saxon alliance became the Saxon invasion and conquest of Kent, after Hengist, heretofore a *Heretogen*, became a king. Whilst his immediate descendants were establishing themselves in succession to him, the contest in the plain of Arderidd took place, which occasioned Myrdhinn's frenzy. Arthur was slain in the battle called by historians the victory of Mountbaden near Bath, 520 A.D.

[The historical Arthur is now regarded by many as having been a 6th century leader, *Guledig*, or "Dux Bellorum" of the northern Cymry of Cumbria and Strathclyde against the encroaching Saxons of the east coast (Bernicia), and the Picts and Scots from beyond the Forth and Clyde. For such would appear to be the, at least, approximately certain result of recent researches, in opposition both to the scepticism of the 17th and 18th centuries as to the existence of an historical Arthur, and to the popular notion of him as a West-of-England king, or king of Wales, or Cornwall. This conclusion had, however, been more or less distinctly suggested by Chalmers, by Sir Walter Scott, by a writer in the *Gentleman's Magazine* (1842), by Mr Nash, and by Dr Burton. Yet this result of special recent researches is still so far from being generally known and accepted, that it may be desirable briefly to indicate the arguments in support of it.

First, then, we have the facts of the northern extension and conflicts of the Cymry in those five centuries, from the 6th to the 10th, which may be distinguished as the Premediæval Period. For these facts our first authorities are the only premediæval British historians, Gildas and Nennius—the *Historia* and *Epistola* of the one having been composed in the 6th, and the earliest of the works that go under the name of the other in the 7th century. Now, in the former there is, at least, nothing to favour that popular notion as to Arthur which is derived from the mediæval chronicles; for the words in the Durham MS., "Qui prope Sabrinum ostium habetur," are now acknowledged to be an interpolation of the 13th century. And the latter is most naturally interpreted as positively affirming that Arthur's conflicts were with the Saxons of Bernicia (Northumberland and the Lothians). It has been contended that this could not be meant, because the Teutonic settlers in the north were Angles. But, in answer to this, it can now be affirmed that the earlier Teutonic settlers in the north were Frisians, a tribe of Saxons; and that the northern settlement of the Angles did not take place till 547, after the time of Arthur. Besides, the bards of the 6th century, to whom are attributed those historical poems, which do not, however, appear to have taken their earliest consistent shape farther back than the 7th century, and which have been recently edited by Mr Skene under the title of the *Four Ancient Books of Wales*,—these Cymric bards—Merlin, Taliessin, Aneurin, and Llywarch Hen—are all connected with the north; of a large proportion of their poems the scenery and events lie in the north; these poems are, in fact, the literature of the Cymric inhabitants of Cumbria and Strathclyde before these kingdoms were subjugated by the Saxon king, Edmund of Wessex, and by him ceded to the Gaelic king, Malcolm king of Scots, in 946; the warriors, whose deeds are celebrated in these poems, were "Gwyr y Gogledd," or men of the north; and the historical Arthur, who figures in five of them, is no southern king, but a Guledig, whose twelve battles are in the north. And, finally, in evidence of the former northern extension of the Cymry, it is as Bretts and Welsh that the inhabitants of Cumbria and Strathclyde are referred to by the contemporary Saxon chroniclers, and in the charters and proclamations of the Scottish kings, David I., Malcolm IV., and William the Lion. So late, indeed, as 1305, we find a recognition of the Cymry as a distinct element of the population of southern Scotland, in the enactment that "the usages of the Bretts shall be abolished and no more used." And it is to Welsh that we must still look for the etymology of the names of the great natural features of that district of southern Scotland which would appear to have been the scene of the battles of the historical Arthur. From Welsh the names Tweed, Teviot, Clyde, Nith, and Annan, and the numerous Esks, Edens, and Levens, &c., are all derived. From Welsh, also, we explain Cheviot, and the names of the border hills. And where the eminences of southern Scotland are not *hills*, *fells*, *laws*, or *knowes*, they are *pens*, as in Wales or Cornwall.

But if, as these various facts (and particularly the connection in which Arthur is mentioned in contemporary, or approximately contemporary, histories and historical poems) lead us to believe, Arthur was a leader of those northern Cymry afterwards absorbed in the population of southern Scotland and the English border, then, in this district, we ought certainly to find localities which can be more or less clearly identified with those mentioned in the earliest historical notices of Arthur, and localities also which, in their names or the traditions associated with them, commemorate his story. Now, it has been shown that such localities are not only found in the district thus defined, but are found there in such numbers as can nowhere else be paralleled. And a very important verification is thus obtained of what, from the scantiness of the earliest sources, might, if thus unsupported, be regarded as a mere hypothesis rather than a theory, with respect to the scene of the battles of the historical Arthur.

Scotland, however, is but the northern extremity of a long line of country in which Arthurian localities are found. What we may call the Arthur-land extends from the Forth and Clyde, or rather from the Grampians, in Scotland, to the Loire in France, and includes (besides the south of Scotland and the north of England) Wales, Somersetshire, Cornwall, and Brittany. It is certain that the scene of the battles of the historical Arthur of the 6th century could have been but a comparatively small area of this vast territory. There must, therefore, have been a migration of Arthurian traditions from the south to the north, or from the north to the south. And if, on quite independent grounds, we find it more probable that such migration of tradition was from the north to the south, rather than from the south to the north, it is evident that we shall have a still further verification of the hypothesis suggested by our examination of the earliest historical records. Now, considering these facts,—Cymric migrations from, but not to, the north; the northern descents of some of the southern dynasties; the upburst of Cymric literature (which belongs in the main to the mediæval period) contemporaneously with the last struggles for, and final loss of, national independence; and the satisfaction, too great to be regardful of historical truth, which a conquered people would have in locally commemorating former victories and heroes of their race,—we cannot but see conditions in the highest degree favourable to the importation from the north of the Arthurian traditions of Wales, the south-west of England, and the north-west of France. On the other hand, we not only find no conditions favourable to the importation of Arthurian traditions from the south into the north, but conditions that would have been positively inimical to the preservation of such traditions, and conditions, therefore, that would seem to make it impossible to explain the existence of Arthurian localities in the north, except on the hypothesis of the north having been the scene of actual Arthurian events. Such conditions are to be found in these facts:—the absorption of the northern Cymry by a kindred race with whom they had never, save temporarily, been at war, viz., the Scots, a brother of whose king they had themselves voluntarily elected to the throne in 918, previously to their being regularly incorporated with the Scottish nationality after the treaty of 946 between Malcolm II. and their Saxon foe, Edmund of Wessex, the preparation for this political incorporation in the 10th century by an ecclesiastical incorporation in the 8th century, through the subversion of the native Cymric Church by the opponent Irish or Columban Church of the Scots with its Gaelic language, whence followed the dying out of the Cymric language, and, finally, the possession by the Scots, with whom the northern Cymry were thus incorporated, of a traditional and poetic literature of their own, which must certainly have greatly opposed the introduction, after their incorporation of the Cymry, of Cymric poetry and tradition, and been highly unfavourable to its preservation, if it had any other than a native historical origin. But yet, further, it is to be noted that Arthurian localities are, speaking generally, found in Scotland only where, in the 6th century, there was a Cymric population, that that part of Scotland in which Arthurian localities are, speaking generally, *not* found, coincides with the ancient kingdoms of the Picts and Scots, and is dotted all over with localities belonging to the other great cycle of Celtic tradition, the Fenian, Fingalian, or Ossianic, and that, while Fingalian localities are not found at all in the Arthurian district, Arthurian localities are found in the Fingalian district, or in the ancient territory of the Picts, only in cases in which their being found in that territory is a strong indication of their having originated in such actual historical facts as they commemorate. (J. S. S.-G.)]

Additions to Historic Facts and Introduction of Mythological Elements.—From the Saxon invasions resulted two emigrations closely succeeding each other of Britons into French Brittany; and the impenetrable forests and mountains of Wales afforded a refuge where the more recent fugitives from Wessex or the north mingled with the earlier exiles from Kent, and hence the subsequent confusion of historic facts. Vortigern of Kent became in the legend the kinsman of Ambrosius of Wessex, the gaps in the history were filled up by mythic reminiscences, and to Arthur was assigned a celestial and miraculous parentage from Uthyr Pendragon, that is to say, Head of the Dragon. Under the form of a cloud this Celtic Jupiter became the father of Arthur, who in the same mythological order gave his name to two constellations, Arthur's chariot, i.e., the Great Bear, and Arthur's lyre. But the word for cloud in Welsh was *Gorlasar* Now, whilst the legend was carried from place to place acquiring new force, the Celtic world had made a stand against Roman and Teutonic ideas; there was, as in Greece, a tendency to explain the earlier myths, no longer understood, into the gross elements of adultery and incest bastardy was not censured, &c. Thus the Uthyr Pendragon of the Romances of the Round Table is a real Jupiter The cloud becomes a man, *Gorloes;* and there is an Alcmene, Ygerne. In short, when Molière has, with more genius than morality, diverted so many generations by his *Amphitryon*, he is striking an old Celtic and Welsh chord. Then Arthur is another Hercules. An advantage, from a national point of view, gained to the legend by Arthur's celestial and pagan origin, is that he becomes by it at once above and akin to all the Celtic chiefs. All the chiefs become his brethren; their sons, who flock to fight under his banner, his *beaux neveux*,—though one, indeed, among them is the traitor Medrod of the Welsh legends, Mordred of the romances. So in dream was founded besides the Round Table which never existed, the Celtic family, which had existed only to destroy itself.

Gradual Formation of the existing character of Arthur in the French Romances.—We have noticed the *bonhomie* which was the chief characteristic of the early Cambrian Arthur. The Arthur born of the recollections and resentments of exile has a more terrible shape. In Brittany, the land of exile, was elaborated this type of a national avenger,—a more moral David (Arthur slays his giant), a Solomon without his scepticism (Arthur was a great author of proverbs). In exile this figure of a Celtic Messiah was graven with some of its most indelible traits. Arthur's own device is very far removed from the gospel; he out-Herods Herod, and, franker than the Jesuitical cruelty of the twelve tables or of Shylock, he goes beyond the *lex talionis;* "a heart for an eye, a head for an arm," he says. Alain de Lille relates, in his commentaries and explanations on the prophecies of Merlin, that in his day any one who, drinking with the Bretons, would tell them that Arthur was dead and never to return, was in danger of being stoned. "Like the dawn, he will arise from his mysterious retreat."

To return to the Arthur of the Round Table, nothing in the romances is touched with more generous sentiment than his invariable affection for Ken (Kay of the Welsh legends), his cunning but clownish, friendly yet treacherous seneschal. For the infant Arthur had been confided by Merlin to Antor, and believed himself his son, while Ken, the real son of Antor gives place to Arthur, is neglected, and all his evil qualities are derived from the wicked nurse to whom he had been given away from his mother; so Arthur was bound to be patient and kind to Ken in after life, and forgive him many times for being "fol et vilain et fel."

We shall not describe the trials to which Arthur submits, those of the sword and of the anvil, for instance, nor the essay in royalty he makes without taking the title of king, though the idea of being made a king, not only by election, but even after examination, is remarkable. Nor shall we relate how, in disguise, aided by his friends Ban and Bohor, he rescues Leogadan from the "Saisnes" (Saxons) and Danes; in disguise, as Merlin explains to Leogadan, who had thrown himself at the feet of his deliverer to entreat to know his name—because thus, without naming himself, should a hero, who is the son of a king, seek out and win his wife. So Arthur woos and weds Guenever, Leogadan's daughter, the Gwenhwyvar of the Welsh tales. The Welsh would have their Arthur cross the Channel to succour their kindred allies in Brittany; the Bretons, in the same way, sent their Arthur into Great Britain, hence confusions which explain each other. One reproach, which has been made at all times, by Mr P. Paris, as by William of Newburgh, to the revengeful instinct which was the soul of the Arthurian legend, is its monstrous vanity, which has depicted Arthur as an opponent and conqueror of the Romans. William of Newburgh has said, "the Britons were little to be feared as warriors, little to be trusted as citizens;" and this passage curiously resembles one in the legend where a Roman knight, before the battle of Langres, is made to exclaim, "Behold, truly the Britons—slow in action, ready in menace!" Whence has arisen this battle of Langres, where Arthur, allied with Claudas, king of the "Terre Déserte," conquers the Romans and destroys their empire. Strange to say, the fictitious battle of Langres has an authentic foundation in history, being but an echo in tradition of the obstinate and successful resistance to the Romans carried on by the Celts of the vast district called the *Tractus Armoricanus,*—a resistance out-lasting, indeed, the Roman power, till Clovis turned it to account and destroyed it; and of Clovis, the treacherous ally of the Armorican Celts, the portrait is easily recognised in the Claudas of the romance.

Rome has been cursed in history more often than she is named in Camille's imprecation in Corneille's play, and we need not wonder at the legend, wherein Arthur calls together a confederation of Greeks, Africans, Spaniards, Parthians, Medes, Libyans, Egyptians, Babylonians, Phrygians, &c., in fact, all nations, against Rome. The legendary hero falls at last, in all his glory and in the midst of his reign of justice, on the field of Camlan. But he is not deserted by that fairy world with whom Shakespeare's soul delighted to dwell; magically transported into the Isle of Avalon, his body is cured of its wounds, and his soul sleeps, while rests his enchanted sword Excalibur, till that day comes when he shall rise again from his mysterious retreat. But that day must dawn for all nations at once, as in the veins of all peoples of Europe is hidden some Celtic blood. On the other hand, progress is barred and darkness dwells where the Celtic race remains unmixed. So it is the destiny of some peoples, while buried for ever as a temporal power, because of their irreparable faults, to live on gloriously for the good of all, but only as an idea, an instruction, a legend. (J. A.)

ARTICHOKE. The common artichoke, *Cynara Scolymus,* is a plant belonging to the Natural Order *Compositæ,* having some resemblance to a large thistle. It has long been esteemed as a culinary vegetable; the parts chiefly employed being the immature receptacle or floret disk, with the lower part of the surrounding leaf-scales, which are known as "artichoke bottoms." In Italy the receptacles, dried, are largely used in soups; those of the cultivated plant as *Carciofo domestico,* and of the wild variety as *Carciofo spinoso.* The Jerusalem artichoke, *Helianthus tuberosus,* is a distinct plant belonging to the same order, cultivated for its root-tubers, which somewhat resemble potatoes, for which they have been proposed as a substitute. It closely resembles the sunflower, and its popular name is a corruption of the Italian *Girasole Articocco,* the sunflower artichoke.

ARTICLES, The Thirty-Nine, of the Church of England, contain the public standard of religious belief adopted by that body. They were drawn up by Archbishop Parker, sanctioned by Convocation in 1562, and published by royal authority in the following year. The general principles of this body of doctrine, and the form into which it was thrown, had been gradually developed during the previous attempts to establish a standard of faith in England. Soon after the authority of the Pope had been thrown off by the English Church, there began to appear wide differences of opinion with regard to the extent of reformation required. One party, the conservative, held by the old practices of the Church of Rome; another, the moderate reformers, desired to abolish these practices on account of the abuses to which they were liable; while the various sects of the Anabaptists were eager for radical reformation both of doctrine and of practice. Religious turbulence and strife prevailed to such an extent that, in 1536, a set of Ten Articles was published by royal authority, intended, as was expressly stated, to "stablyshe Christen quietnes and unitie among us, and to avoid contentious opinions." A considerable share in the composition of this code was taken by Henry himself. The articles were evidently intended as a compromise; they contained much that was afterwards rejected by the church, and do not seem to have given general satisfaction. They were partially, though not authoritatively, superseded by the publication, in 1537, of the *Institution of a Christian Man.* For two or three years before this negotiations had been carried on with the Continental reformers, and proposals had been made for a general conference at which some universal articles of faith might be considered. The conference took place but did not attain the end desired, for Henry, at first favourably disposed, was swayed by the influence of the anti-reformation party; and Cranmer, while able to come to agreement with the German deputation so far as points of doctrine were concerned, saw clearly that it would be a hopeless task to try to abolish all the ancient ceremonies. The increasing influence of the conservative party led to the passing, by Convocation and Parliament, in 1539, of Henry's SIX ARTICLES, the "bloody statute," or "whip with six strings," as they were then called, from the cruel persecutions to which they gave rise. These articles enforced belief in transubstantiation, declared that communion in both kinds was unnecessary, that the marriage of priests was unlawful, that vows of chastity or widowhood were absolutely binding, that private masses and auricular confession were expedient and necessary. The severity of these doctrines was mitigated by the third authorised formulary of Henry's reign, *The Necessary Doctrine and Erudition for any Christian Man*, called the "King's Book," and published in 1543. The conference with the Germans, though not entirely successful, had not been without fruit. Among Cranmer's papers has been found a set of Thirteen Articles bearing evident traces of the Continental ideas, and highly interesting on account of the influence it exercised on the later formularies. Many of these articles are drawn directly from the Augsburg Confession, and there seems no doubt that they thus formed an intermediate step between that Confession and the FORTY-TWO ARTICLES of Edward. These were drawn up by Cranmer in obedience to the command of the king and privy council, who, in 1551, ordered the archbishop to "frame a book of articles of religion, for the preserving and maintaining peace and unity of doctrine in this church, that, being finished, they might be set forth by public authority." Great care was taken in their preparation; the first draft was sent round to the bishops, then revised by Cranmer, submitted to Cheke and Cecil, and to the six royal chaplains, and finally laid before the council. In 1553 the mandate enjoining subscription to them was granted by the king, but the articles had already been printed in English. In the same year they were published in Latin, and appended to a short catechism of Christian doctrine. It has been much disputed whether these articles were sanctioned by Convocation, or were only circulated by order of council; on the whole, the balance of probability seems to be in favour of the supposition that they had received ecclesiastical sanction (Hardwick, *History of the Articles*, 106–112).

During the reign of Mary these articles were suppressed, but, on the accession of Elizabeth and the elevation of Parker to the see of Canterbury, attention was again directed to the framing of some standard body of truth. A series of Eleven Articles was drawn up in 1559, and was in use for some time; it had not, however, full authority, though it was enforced in Ireland until 1615. In 1562 the houses of Convocation were summoned, and Parker laid before them a revised copy of the Forty-Two Articles. In the work of revision he had been assisted by Bishops Grindal, Horn, and Fox. The changes introduced by them were, for the most part, Lutheran in tendency, and were probably influenced by the Würtemberg Confession of 1551. Articles v., xii., xxix., and xxx. of the present set were newly introduced; x., xvi., xix. (part being transferred to the present vii.), and xli. of the old series were omitted. Seventeen other articles were modified by partial omission, alteration, or substitution. Convocation further struck out Articles xxxix., xl., and xlii.; made considerable alterations in iii. and xxviii., and some slight changes in viii., xv., xxii., xxix., and xxxiii. A Latin manuscript of Parker's, containing a list of signatures, might be supposed to give the final state of the document, but it differs from the extract taken in 1637 by Laud's order from the registers, both in regard to the signatures, and in the omission of the first clause of Article xx. The articles, now thirty-nine in number, were submitted to the queen, who is said to have read and examined them. After nearly a year's delay they were published in Latin. In this edition the disputed clause of Article xx. is found, and Article xxix. is wholly omitted. In the English version, printed in the same year, the clause of Article xx. is wanting. In all editions after 1571, Article xxix. is inserted, and, with one exception, the same is true of the clause in Article xx. A law (13 Eliz. c. 12) was passed in 1571, ordaining that the clergy "should subscribe to all the articles which only concern the confession of a true Christian faith, and the doctrine of the sacraments." Convocation of the same year inserted Article xxix., made a few slight changes, added a list of the Apocryphal books, and thus gave the articles their present form. The only serious attempt at alteration was made in 1595, when the Primate, Whitgift, accepted a series of articles proposed by Dr Whitaker of Cambridge. These, generally known as the *Lambeth Articles*, were strongly Calvinistic in tone. They did not receive sanction, and were immediately suppressed. At a later date (1604) it was again sought to introduce them, but the attempt was unsuccessful. The canons of 1604 enforced subscription, while the general relation of the articles to the church was defined by the royal declaration of 1628 (now prefixed to them), which enjoins the settlement of disputed points by Convocation, the acceptation of the articles in their plain and full bearing, and the interpretation of them in their literal and grammatical sense.

The articles are not intended to be a complete system of theology, but only enumerate certain truths of such primary importance that any one denying them is thereby excluded from the church. They do not, however, furnish merely a negative test; they were framed not only for the avoidance of diversity of opinion, but for the establishment of consent regarding true religion. Accordingly, they treat in order of the main points of theological doctrine, and may be classified thus:—(1.) Articles i.–v., the doctrine of the Trinity; (2.) Articles vi.–viii., the rule of faith or sources of our knowledge of religious matters; (3.) Articles ix.–xviii., the doctrines which concern the Christian as an individual, *i.e.*, sin, redemption, and their cognate notions; (4.) Articles xix.–xxxix., the necessary relations of Christians as members of a religious community, including the general theory of the church, and the doctrine of the sacraments. The Church of Ireland continued to use the Eleven Articles until 1615, when a more elaborate code was drawn up by Ussher. This, in 1635, was superseded by the Thirty-Nine Articles, which were then adopted by the Irish Church. The Episcopal Church in Scotland accepted the articles in 1804, and in America the church subscribed to them in 1801, excluding, however, the Athanasian Creed.

See Abp. Laurence, *Bampton Lectures*, 1804, new ed. 1853; Lamb, *Historical Account of the Thirty-Nine Articles*, 1835; Hardwick, *History of the Articles of Religion*, 1859.

ARTICULATA, the name given by Cuvier to his third great division of the animal kingdom. *Arthropoda* is the designation now generally adopted, which includes the *Crustacea, Arachnida, Myriapoda*, and *Insecta*, but excludes the *Annelida*, which Cuvier classed with these among the *Articulata*. See ARTHROPODA.

ARTILLERY

THE modern term *Artillery* is used in two senses,—firstly, to designate the *matériel* of artillery, *i.e.*, the guns, &c.; secondly, the *personnel* and organisation by which the power of this arm is wielded. The word itself is derived by some from "arcus," a bow; by others from "ars telaria," signifying bows, arrows, and all implements of projectile warfare. The earliest forms of artillery were the "engines invented by cunning men to shoot arrows and great stones," of which we read in the Old Testament; these developed, with the progress of military art, into the more elaborate machines used by the Romans under the names of *catapulta*, *balista*, battering-ram, &c.; and under various forms and names this "mechanical artillery" continued in use, until the discovery of a propelling agent so powerful as to supersede all others and revolutionise both the implements and the art of war.

The history of artillery proper may be said to date from the discovery of gunpowder. This is popularly attributed to the two monks, Roger Bacon and Bartholdus Schiraz, about the end of the 13th century (see GUNPOWDER); but there is ample evidence that substances of somewhat similar composition and powers had been known and used for purposes of war in the East at far earlier times. The Chinese seem to have been the first discoverers of explosive compounds as engines of war, and to have used them for several centuries before the Christian era; and their "thunder of the earth," produced by filling a huge bombshell with some such compound, and exploding it at the proper moment, is spoken of as early as the 3d or 4th centuries of our era. According to Father Amyot, stone mortars, projecting stone balls, were used by them in the 8th century; and although they were first instructed in the scientific casting of cannon by missionaries in the 17th century, there is evidence of large cannon and wall pieces of rough construction having been in use as early as the 12th century. The inhabitants of India seem to have possessed fire-arms of some sort as early as the time of Alexander; but the information is too meagre to admit of more than the merest speculation as to their nature. The celebrated Greek fire, of which we have ample accounts, was usually in a liquid form, and vomited through long copper tubes, with which the bows of vessels of war were provided, or projected in fire-balls, or by means of arrows and javelins around which flax was twisted. It was used by the Romans of the Eastern empire with much effect, especially at the defences of Constantinople (668–675 and 716–718 A.D.), and the secret of its manufacture was preserved with a superstitious care for nearly 400 years; but it afterwards passed into the hands of the Mahometans, and was much used by them in their wars with the Christians. The Moors first introduced fire-arms in western Europe; according to Condé, they used artillery against Saragossa in 1118 A.D., and a little later they defended Niebla by means of machines which threw darts and stones through the agency of fire.

The application of gunpowder to projectile warfare, and the use of cannon, became general in Europe during the 14th century. Mention is made, however, of isolated instances of their employment at earlier periods, especially among the Moors. Artillery is also said to have been used by Henry III. of England during the rebellion of the Duke of Gloucester in 1267, and by the Spaniards against Cordova in 1280 and against Gibraltar in 1306. But it is held by those well qualified to judge, that the first unquestionable testimony of the employment of cannon is in 1338 under Edward III. of England. The substitution of the new engine for the old mechanical artillery was gradual, and was not effected without opposition; and in the 13th and early part of the 14th centuries, we still find various machines, such as the trebuchet, onazer, scorpion, and espringal, whose action was dependent on the elasticity of twisted cords, used to hurl stones, Greek fire, &c.

The earliest trace of an artillery organisation, such as now plays so important a part in all great armies, is found in the middle of the 14th century. In 1344 Edward III. formed an artillery train and an ordnance establishment, numbering 340 men; but of these only twelve were termed artillerymen and gunners, the remainder consisting of waggoners, engineers, and artificers of various kinds. The ordnance establishment at the siege of Harfleur, in 1415, included twenty-five master gunners and fifty "servitour gunners." The gunner of those days seems to have been the captain of the gun, and to have had general charge of the guns and stores, with the especial duty of laying and firing the piece in action. The manufacturing establishments, now maintained on so gigantic a scale, do not seem to have sprung up till considerably later. Piobert states that gun-foundries were established in France in 1377; but we have no trace of them in Germany till 1440, and record of them is wanting in England until 1521.

The guns of the 14th century were of the rudest make, cumbrous and inefficient, and though an advance on the earlier machines, and useful in sieges, still played but little part in battles. Whether Edward III. used them at Creci or not (a point which has been much debated), it may safely be affirmed that they had but little to do with the result of that day. Progress, however, began to show itself in the 15th century; the "bombards" were replaced by brass guns, and the cumbrous beds, upon which the earlier ordnance were transported, gave way to rude artillery carriages on wheels; and iron was substituted for stone in the manufacture of projectiles. The first step towards a better organisation and some tactical system appears to have been made towards the end of the 15th century by Charles VIII. of France, who used a numerous artillery in his Italian campaigns; and Louis XII. largely owed his successes in Italy to this arm. Francis I. still further increased its mobility, adopting a lighter construction for field-guns, and having them drawn by the best description of horses; and in the defeat of the Swiss in 1515, "the French artillery played a new and distinguished part, not only by protecting the centre of the army from the charges of the Swiss phalanxes, and causing them excessive loss, but also by rapidly taking up such positions from time to time during the battle as enabled the guns to play upon the flanks of the attacking columns."[1] In England also considerable attention was bestowed on ordnance matters during this period, though the progress was not so great. In 1456 it is stated that a commission was issued to John Judd, as *master-general of the ordnance;* and in 1483 (Richard III.), Rauf Bigod was appointed master of the ordnance, an office which continued down to 1852. These early masters of the ordnance personally commanded the artillery in expeditions and wars, besides being responsible for the general administration of the *personnel* and *matériel* of such artillery as then existed. Henry VII. and Henry VIII. did much to advance the progress of artillery. Tartaglia[2] gives tables of the different cannon in use about this time. The heavy pieces, *i.e., culverins*, &c., were drawn by oxen, and corresponded to those now in use for

[2] *Three Books of Colloquies concerning the Art of Shooting.*

siege or position purposes, while the field guns appear to have been the 2, 4, 6½, and 8 pounders,—*falcons, falconets*, and *sakers*. No permanent artillery trains existed at this time; the *personnel* was obtained by withdrawing gunners from garrisons, and supplementing them with men hired for the occasion, and the cattle required for transport were also hired. The artillery train on service included the ammunition waggons, pontoons, and a large proportion of artificers, besides the men actually required to serve the gun, corresponding nearly to the artillery park of the present day, and had its position assigned in camp and on the march. "On the march the train was preceded by an advanced guard of light cavalry to protect it. The first portion of this troop carried hatchets and saws; the second, instruments and implements for the construction of machines; the third, sledge-hammers, iron wedges, and pickaxes; finally, the last were provided with pioneers' implements. After these came carriages loaded with guns, capstans, levers, and other like machines; these were followed by the light pieces, by the heavy siege guns, by ammunition waggons, by pontoons and the necessary men for them, by the artillery artificers, and, lastly, by the baggage."[1]

16th century. The 16th century was not marked by any great advance in artillery science, though the number of guns which accompanied an army had increased considerably—as many as 1600 gunners, cannoneers, armourers, and clerks of the ordnance, being attached to Lord Mountjoy's army in Ireland in 1599. The artillery tactics were simple; the guns usually deployed in advance of the troops and fired a few rounds, but from their want of mobility could neither accompany an advance nor protect a retreat, and were generally captured on the first advance of the enemy. Greater progress, however, was made in the attack and defence of fortresses by artillery. Vertical fire was used to a considerable extent, and seems to have been conducted by artificers while the "cannoneers" served the guns. In

17th century. England but little advance was made even in the 17th century, and the commencement of the Great Rebellion found the artillery of England in a very feeble and backward state. Two books by artillerymen of those days[2] give us much information on its condition, and a very complete account of the "Field Artillery of the Great Rebellion" is furnished by Captain H. W. L. Hime, R.A.[3] The guns chiefly used were the light pieces known as "minion," "saker," and "demi-culverin," *i.e.*, 3-pounder, 5-pounder, and 9-pounder respectively. The heavier pieces being used in sieges and garrisons, and ranging from the "whole culverin," or 15-pounder, to the "Canon Royall," or 63-pounder. The carriages were cumbrous. "They were formed of two large cheeks or brackets, whose general outline was much the same as the brackets of our own bracket-trails, connected together by four transoms." The transport of the ammunition was in carts or wheelbarrows, or on men's backs. The gunners walked beside the gun, and, as in later times, their pace was a measure of the mobility of the field artillery. Cartridges, when used, were made of paper or canvas, but an iron ladle was preferred. The following words of command show the gun-drill of those days:—

1. Put back your piece.
2. Order your piece to load.
3. Search your piece.
4. Sponge your piece.
5. Fill your ladle.
6. Put in your powder.
7. Empty your ladle.
8. Put up your powder.
9. Thrust home your wad.
10. Regard your shot.
11. Put home your shot gently.
12. Thrust home your last wad with three strokes.
13. Gauge your piece.

As to the draught, twenty-three horses were required for a cannon on good ground, fifteen or seventeen for the demi-cannon, and nine for a culverin. The proportion of guns to men was 1 per 1000. The artillery general was a greater man in those days than in more modern times, as we find that "the generall of the artillery hath alwayes a part of the charge, and when the chief generall is absent, he is to command all the army." The "gentlemen of the artillery" seem to answer to our present majors, and the duties of the "gunners" were much the same as those now performed by lieutenants. In the Scotch invasion of 1640, leather guns were used with effect against the English in the passage of the Scots over the river Tyne. When Charles I. took the field in 1642, the earl of Peterborough, as parliamentary general of artillery, had a large train under his orders, but such was its want of mobility, that he was obliged to leave his guns behind him for a time. It came up, however, at last, and was used at the battle of Edgehill, 23d October 1642. In 1643, at Braddoch Doun, an instance occurred of the use of field artillery first masked by cavalry; and at Roundway Lord Wilmot handled his guns so well that he prepared the way for his cavalry, and finally was able to seize the enemy's guns and turn them against him. At other affairs, however, the artillery seems to have been comparatively useless, and the presence of twenty-five guns on the Royalist side at Marston Moor was neutralised by Cromwell's flank attack; and in no battles of this war did the artillery assume the importance it had already attained on the Continent.

The first half of this century forms an era in the history of this arm in Europe. Henry IV. of France was among the first to recognise its coming importance, and occupied himself diligently with improving it. His minister, Sully, was named master-general, and during the last ten years of his reign (1600–1610), he may be said to have created an artillery. More than 400 guns were turned out, including a number of field-pieces. Maurice of Nassau also helped to develop the use of this arm. But it was under the great Swedish warrior Gustavus Adolphus that artillery first began to take its true position on the battle-field. Gustavus Adolphus. Recognising the necessity for the mobility of field artillery, he introduced "*Kalter*" guns, "consisting of a thin cylinder of beaten copper screwed into a brass breech, whose chamber was strengthened by four bands of iron, the tube itself being covered with layers of mastic, over which cords were rolled firmly round its whole length and equalised by a layer of plaster, a coating of leather, boiled and varnished, completing the piece."[4] This primitive field artillery was drawn and served by two men, and was first used in his Polish war. The guns could naturally bear but a small charge; the great point gained was *mobility*, all guns heavier than 12-pounders being separated from field artillery. In his German campaigns he used iron 4-pounder guns, weighing about 5¼ cwt., and drawn by two horses. Rapidity of fire was obtained by the use of cartridges instead of the old method of ladling the powder. Gustavus attached two of these guns to each regiment, and placed them under the orders of the colonel. Gustavus Adolphus may therefore be said to be the father of the battalion system of guns,—a system which had its advantages in those days of imperfect organisation, but, like many other things, was carried down to a late date when the necessity for the system had entirely disappeared. But he also appreciated the value of concentration of fire, and frequently massed his guns in strong batteries at the centre and flanks. He appears to have been fully alive to the necessity of having both a heavy and light artillery, and it was his practice to retire his heavy guns, protecting a

retreat by the field artillery. It was in the celebrated Thirty Years' War that his artillery showed the advantages which it could win when handled properly. The artillery of the Imperialists was as cumbrous as that of their Swedish adversaries was mobile. Tilly's guns were chiefly 24-pounders, each requiring twenty transport horses and twelve horses for the waggons, while the service of the guns was primitive and defective, and they could hardly even be moved during the course of an action. The first battle of Leipsic was fought the 7th September 1631, between the allied Swedes and Saxons under Gustavus Adolphus and the Imperialists under Tilly. The Imperialist artillery was badly disposed on a range of hills in rear of their position, so that any forward movement would effectually mask the fire of the guns. Gustavus, on the other hand, advanced his guns more, and covered his front with 100 guns, which he was able to use with considerable effect. The next action in which the use of the artillery is remarkable was the passage of the Lech, a tributary of the Danube. Tilly had taken up a position on the right bank of the river between Augsburg and Rain, and awaited attack. On the night of the 3d April 1632 the Swedish army threw up earth-works, upon which were mounted seventy-two pieces of artillery. Gustavus, taking advantage of the re-entering bend of the river, brought such a converging fire upon the Imperialists that he forced them to retire and gained the passage of the stream. At the battle of Lützen, 6th November 1632, Wallenstein had taken advantage of certain eminences and rising ground in his position to post his guns in batteries of from four to fourteen pieces, while Gustavus placed powerful batteries on the wings and centre of his line. The battle closed the glorious career of this great warrior, who was struck down in the hour of victory. During his life he had done much to forward the science of artillery. He had increased its mobility and rapidity of fire, and raised the proportion of guns to over six per 1000 men; and though he may be said to have been the originator of the battalion system, with its attendant evils of dispersion of guns, he checked this evil by keeping in hand a considerable reserve.

Further progress was made in construction and organisation during the latter part of the century. In England the laboratory at Woolwich was established in 1672, and a great reorganisation of the artillery took place in 1682 under the master-general, Lord Dartmouth. About that time we read, that at the Hounslow camp "brass 3-pounders, under gentlemen of the ordnance, were escorted to their places by the grenadiers of the various regiments," an example of the tactical system of "battalion guns" already spoken of. The train of artillery with which James II. prepared to meet the invasion of 1688 was a considerable one; details of it will be found at page 53 of Duncan's *History of the Royal Artillery*. William III. (1689) introduced foreign artillery, and undertook the reorganisation of the *personnel*. He formed the first regimental establishment. Howitzers, mortars, and hand-grenades were introduced during this period, being used principally by the Dutch and English. In France the improvements under Louis XIV. seem to have been made chiefly in siege artillery. Heavy guns of position were much used, and there appears to have been a disposition to regard batteries of this kind, covered by epaulements, as in field fortifications, as the natural rôle of artillery. Louis XIV., however, was the first to give a permanent foundation to the new arm. In 1671 he raised a regiment of royal fusiliers as artillerymen, composed of gunners and workmen. Schools of instruction were established, and the arm recognised as a special branch. Improvements were also effected in the *matériel*. The calibres were reduced in number and made uniform, and those then adopted have remained unaltered up to the present day, some having been rifled. Carriages were improved. "Siege and field carriages had heavy bracket-trails, but were provided with limbers having a straight pintail on the top, like an old service siege limber."[1] Platform waggons were used to transport guns; *wrought-iron* field carriages and mortar carriages were used; and the carriage for coast batteries was little dissimilar to the standing gun-carriage of the present day.

The 18th century was fruitful in artillery progress. In England it saw the Royal Regiment of Artillery permanently established, and rapid strides made on the Continent in every branch of the arm. The Duke of Marlborough was appointed master-general of the ordnance on the accession of Queen Anne, in 1702, and in the same year war was declared with Germany and the States-General. We have but scanty record of the handling of his artillery by this great general; but at Blenheim it is said a strong battery, posted on the allied right wing, greatly assisted by its enfilade fire; and at Malplaquet, Marlborough deployed forty guns in the centre of his position. The artillery trains were considerably increased. In 1706 forty-six guns and sixty mortars formed the artillery of a force of 11,000 men, the mortars being used mounted upon travelling carriages. The history of the "Royal Regiment of Artillery" commences from the 26th May 1716, when the artillery which had so long existed was formed into two permanent companies of Royal Artillery. In 1727 the organisation was expanded into four complete companies, commanded by a colonel, lieut.-colonel, and a major, and in 1740 two more companies were added. A company consisted of 5 officers, 4 fire-workers, 18 non-commissioned officers and bombardiers, 30 gunners and cadet gunners, 48 matrosses and cadet matrosses, and 2 drummers. Albert Borgard was the first colonel. By birth a Dane, he served first in the Danish army and afterwards in the Prussian service, and subsequently entered that of England. He was adjutant of the short-lived regiment formed by William III., and died in 1751 at the age of 92. In 1741 the Royal Military Academy was instituted at Woolwich for the instruction of cadets, and of officers and men of the artillery. The cadets were accommodated in buildings at the Warren, and it was not till 1806 that the new academy was opened at the foot of Shooter's Hill. In 1748 a company of Royal Artillery went to the East Indies and took part in the siege of Pondicherry, subsequently forming the nucleus of the Indian artilleries. In 1755 four additional companies were raised for service in the East Indies, and in 1757 the regiment had increased to twenty-four companies. A Royal Irish Artillery corps was also formed, which gradually increased from a small nucleus to a strength of twenty companies, and was amalgamated with the Royal Artillery in 1801. About this period (the middle of 18th century) the guns in use consisted of 24-pounders, 12-pounders, 6-pounders, and 3-pounders. The guns were divided into brigades, corresponding to the present batteries, of four, five, and six guns respectively, and began to be separated into "heavy" and "light" brigades. Each field gun was drawn by four horses, the two leaders being ridden by artillerymen, and had 100 rounds of shot and 30 rounds of grape. Three companies of the Royal Artillery took part in the battle of Minden in 1759, and were handled with great success; and even in those days the English artillery won praise from foreign critics. Decker says,[2] "The English artillery was distinguished by its lightness, its elegance, and the good quality of its materials. In the battle of Marburg (1760), although the English artillery

was not horsed, it followed Lord Granby's cavalry at a trot, and was always ready to engage." "The English artillery," says Tempelhof, "could not have been better served; it followed the enemy with such vivacity, and maintained its fire so well, that it was impossible for the latter to re-form." In the great blockade and siege of Gibraltar (1779–83), the gallantry and devotion of the garrison artillery were conspicuous.

Before passing on to the era formed by the great war against Napoleon, it is necessary to trace the progress made by this arm on the Continent.

Prussia. The Prussian artillery was very backward at the beginning of this century. In 1688 the Brandenburg (Prussian) artillery numbered only 300 men; and at the death of Frederick-William I., in 1740, there was only one battalion of field artillery of six companies, and one of garrison artillery of four companies. Nor did Frederick the Great at first place much value upon its services. But experience soon convinced him of the necessity for creating an efficient and mobile field artillery. His first efforts in this direction were not successful; and though the Prussian artillery contributed much to Frederick's victory at Rossbach, it was usually no match for the excellent and well-handled Austrian artillery. But the gradual destruction of his veteran infantry obliged him to devote more attention to this arm, he considerably raised the proportion of guns, and in 1759 he formed the first horse artillery, consisting of a battery of ten light 6-pounders (afterwards changed to six 6-pounders) and two 7-pounder howitzers. Frederick placed great value on howitzers, and made much use of them against entrenched positions, and at the close of the war, after experiments on a large scale, ordered forty heavy howitzers to be attached to each army corps. Frederick seems to have made the mistake during the Seven Years' War of trying to bring heavy artillery into the field, instead of trying to lighten his artillery generally. But he gave a great impetus to the progress of artillery. He raised the proportion of guns from $2\frac{1}{2}$ and 3 per 1000 men in the Silesian wars to 5 or 6 per 1000 at the end of the Seven Years' War. He created a horse artillery which in rapidity of movement could rival cavalry; and commenced the formation of a real field artillery by the adoption of a number of light pieces and howitzers, while the heavier guns were relegated to parks for siege and position purposes. And his wars brought forward three important tactical principles in the employment of artillery,—the establishment of smaller batteries at important points in the line of battle in lieu of the old formations at the centre and flanks, opening the battle and protecting the deployment of columns by light guns, and changing the position of batteries according to the course of the action.

Russia and Austria, though they produced no great military leader like Frederick, were ahead of Prussia in the
Russia. development of this particular arm. In Russia its importance had always been recognised, and large numbers of guns employed, while each dragoon regiment had three "licornes" or howitzers attached, with mounted gunners, forming a
Austria. species of horse artillery. In Austria, though the tactical employment of the artillery was often defective, its general excellence was pre-eminent, and it was ably organised under Prince Lichtenstein, the chief of artillery. But it
France. was in France that the experience of Frederick's wars was best utilised, and the great strides to a more perfect system were made. At the commencement of the century French artillery had made but little progress. The carriages and waggons were driven by waggoners on foot, and on the field of battle the guns were dragged about by ropes or remained stationary. Hollow projectiles had made their appearance, and lead tarred balls arranged round an axis and kept together by a net, and termed *grape*, were employed. But the ammunition generally was of a rough and primitive description. Towards the middle of the century some improvements were made. Field guns and carriages were lightened, and the guns separated into brigades. Siege cartridges were introduced, the ladle being abolished, and shot with wooden bottoms or *sabots* invented. But it was under General Gribeauval, in 1765, that the great reforms in the French artillery were commenced. This officer had been sent to Austria during the Seven Years' War, and had held an artillery command under Prince Lichtenstein. Struck with the improvements effected in Austria, he strove, on his return, to build up a complete system both of *personnel* and *matériel*, creating a distinct *matériel* for field, siege, garrison, and coast artillery. Alive to the vital importance of mobility for field artillery, he dismissed from the park all pieces of greater calibre than 12-pounders; and reduced the length (necessary for the service of guns in embrasures and behind parapets) and weight of those retained. He also reduced the charge and the windage. His reforms were resisted, and for a time successfully; but in 1776 he became first inspector-general of artillery, and was able to carry through the improvements which will ever cause his name to be celebrated. For many years artillery had been separated into regimental or battalion guns, artillery of position, garrison, and siege artillery, the position guns being distributed in large batteries on the flanks or in front of a position, and the siege artillery collected in a park or train. The field artillery of the new system included 4-pounder regimental guns, and for the park 8 and 12 pounders, with 6-inch howitzers. The ammunition was improved by the introduction of "case" or canisters of sheet-iron holding cast-iron balls, the old grape and case being abolished.

The carriages were constructed on a uniform model, strengthened with iron, the limber-wheels heightened, and the draught diminished. Iron axletrees were introduced, straight pintails on the top of the limbers, and poles took the place of shafts. Boxes on the carriage held part of the ammunition. Travelling trunnion poles were introduced. The horses were harnessed in pairs, instead of in file as formerly, and the *prolong* of rope was introduced to unite the trail of the gun and the limber in slow retiring movements. A new ammunition waggon, carrying fixed ammunition, was also invented. The service of the guns was improved by the introduction of cross-headed elevating screws and tangent scales,—the later experiments exploding the old false ideas with regard to the absolute flatness of the path of a projectile. The manner in which the teams were driven remained much the same; but the bricole was introduced, a collar with rope and hook, to which the gunners and foot soldiers harnessed themselves. For siege and garrison service Gribeauval adopted the 16-pounder and 12-pounder guns, 8-inch howitzer, and 10-inch mortar; the 12, 10, and 8-inch gomer mortars being introduced in 1785. Siege only differed from field carriages in having shafts in lieu of poles. Gribeauval introduced for garrison service a carriage with wheels in front and a truck in rear, while for coast service traversing platforms were adopted, having a bolt in front and a truck in rear running upon a circular racer. The great step made was in a uniform construction being adopted for all *matériel*, and the parts susceptible made interchangeable.

In 1765 the *personnel* of the French artillery was reorganised. The field artillery with an army was divided into regimental guns and corps or reserve artillery. This latter portion was subdivided into divisions of eight guns of the same calibre. A company of artillery was also attached to each brigade of four battalions. The battery or division was thus made the tactical unit, with guns, munitions, and gunners complete, the horses and drivers being added at a later date. The French horse artillery dates from 1791. Horsemen and gunners were combined, each class learning the work of the other. Companies were attached to a battery of six guns, and in 1793, when the divisional organisation was adopted, artillery was attached to divisions in proportionate strength, and regimental guns were abandoned and entirely suppressed by Napoleon in 1796. The reforms of Gribeauval bore fruit in the wars of the republic. The tables of construction which had been drawn up secured a uniformity of manufacture, the reduction of the weight of the gun gave mobility to the field artillery, and enabled it to be used with the greatest effect in the new tactics which Napoleon introduced; and the last step in the complete organisation of field artillery was made in 1800, when the establishment of a driver corps of soldiers put an end to the old system of horsing by contract.

War of the French Revolution.

At the commencement of our wars on the Continent in 1793, the British artillery was in anything but an efficient condition. The guns were dispersed among the infantry, they were horsed in single train, the ammunition was packed in rough deal boxes, the ammunition waggons were cumbrous and ill-constructed, the drivers were mere carters on foot with long whips, and the whole equipment was scarcely able to break from a foot pace.[1] Prior to the Peninsular war, however, the exertions of an able officer, Major Spearman, had done much to bring about an improved state of things. Horse artillery had been introduced in 1793, and the driver corps established in 1794. The battalion or regimental guns were abolished in 1802, and field batteries or "brigades" of six guns were formed, horse artillery batteries being styled troops. Military drivers were introduced, the horses teamed in pairs, the drivers being mounted on the off-horses, while eight gunners were carried on the limbers and waggons. The equipment was lightened and simplified, the ammunition was properly packed, and a correct system of manœuvres was introduced. The invention of shrapnel shell by Major Shrapnel in 1803, and the transformation of the rocket from a mere signal to a destructive engine by Sir W. Congreve in 1806, also added to artillery power.

The composition of a troop of horse artillery from 1805 to 1807 was about as follows:—

	Men.					Animals.	Carriages.
	Officers.	N. C. Officers.	Gunners.	Drivers.	Artificers.		
Horse Artillery	5	14	85	60	...	164 horses	19
Driver Corps	...	1	...	20	3	36 mules	...

The composition of a field "brigade" between 1808 and 1816 was as follows:—

	Men.					Animals.	Carriages.
	Officers.	N. C. Officers.	Gunners.	Drivers.	Artificers.		
Company of Artillery	5	17	123	...	...	160 horses	19
Driver Corps	1	9	...	96	10	10 mules	...

The troops of horse artillery were armed with five guns (6 or 9 pounders) and one $5\frac{1}{2}$-inch howitzer. The field brigades were likewise armed with five guns and one howitzer, the guns ranging from light 6-pounders to 12-pounders. At Waterloo there were four different armaments for field brigades. The "driver corps," raised in 1794, consisted of a few subaltern officers, with non-commissioned officers, artificers, drivers, and horses. The corps was divided into troops, the addition of one of which to a company of foot artillery converted it into a field "brigade." The horse artillery possessed both drivers and horses, and required very limited assistance from the driver corps.

Although the British artillery distinguished itself on many occasions during the Peninsular war[2] and at Waterloo, and French officers were loud in its praise, the field artillery still suffered from the great evil, want of mobility. Matters, however, had somewhat improved by the end of the war. Great augmentations had also taken place during the war, and in 1815 the Royal Artillery numbered 23,085 of all ranks. After the peace it was again reduced, and horse artillery troops and field brigades were placed on a skeleton establishment of two guns each. In 1822 the driver corps was abolished, and the men and horses distributed among the field battalions, men being enlisted as "gunners and drivers." This system did not work well, owing to the difficulty of finding men who could combine such dissimilar duties. During the Peninsular war field guns and waggons were drawn by six and four horses respectively; but in 1820 a committee recommended eight horses for heavy field guns, and six for light guns and waggons; and after considerable opposition this was ultimately adopted. For some years the artillery, in common with the other branches of the British army, was kept down to the lowest state, but in 1848 the troops of horse artillery were increased to four pieces, and in 1852 they and the field batteries were raised to six guns. The field and horse artillery was increased to twenty batteries, giving a total of 120 guns. Shortly before the Crimean war a further increase of several battalions took place; but notwithstanding these various augmentations, both field and garrison artillery were entirely insufficient during the siege. At this time the field artillery consisted of "position batteries" of three 18-pounders and one 8-inch howitzer, or of four 12-pounders and two 32-pounder howitzers; of "field batteries" of four 9-pounders and two 24-pounder howitzers, and of "horse artillery troops" of four 6-pounders and two 12-pounder howitzers. In 1858 drivers, specially enlisted and trained, were permanently attached to each field battery. In 1859 the Royal Regiment of Artillery, which had increased to fifteen battalions of field and garrison artillery and one brigade of horse artillery was reorganised and divided into horse, field, and garrison brigades—each an administrative unit complete in itself with its own staff, and in 1862 the Indian artillery was amalgamated with the Royal Artillery, and the total strength of establishment was five horse and twenty five field and garrison brigades.

Progress of British artillery since 1815.

Important changes also took place in the *matériel* about this period. The advantages of rifling had been long known, but it was not practically applied to ordnance until 1846. Rifled guns were first used by the British artillery at the siege of Sebastopol, but with no great effect, owing to defective construction. A few years later the introduction of the Armstrong breech-loading rifled gun (first used in the China campaign of 1860) caused a great alteration in the equipment of the British artillery. The 7-inch gun of 82 cwt. was introduced for garrison service and even for siege purposes; 40-pounders, on block trail travelling carriages, for batteries of position, while 20-pounders were intended for the same or heavy field batteries; the

[1] *British Gunner.*

[2] For an interesting summary of the employment of artillery in the Peninsular War, see a paper by Captain Hime, R.A., No. 5, vol. viii., *Proceedings of R.A. Institution*, 1873.

12-pounder of 8 cwt. being for the armament of field, and the 9-pounder of 6 cwt. for horse artillery. The field carriages were provided with a gun-metal "saddle" worked by a lever and hand-wheel for traversing, and ball-and-socket elevating screw. The limbers and ammunition waggons were constructed of an improved pattern, and the whole equipment showed a great advance in efficiency; 124 rounds per gun were carried on the gun carriage and ammunition waggon, and a further "reserve" in a second line of waggons. The system of attaching small arm ammunition waggons to field artillery was abolished, and in future separate "ammunition columns" will convey this as well as reserve ammunition for artillery. The Armstrong system, which was but little tested in the field, has since 1873 been almost entirely superseded by muzzle-loading rifled guns, which will be described further on.

France. In France a new era for artillery opened with the wars of the consulate and the empire. The *matériel* underwent no great alteration, the 6-pounder being substituted for the 8 and 4-pounders for horse and divisional artillery, and a 24-pounder howitzer introduced. But beyond all other changes, we may note the increased tactical employment of artillery under the great artillery officer, Napoleon I. It is to his wars that we first look for instances of the important effects produced by this arm, in that concentration of fire which in those days was only produced by massing guns.[1] After the peace of 1815 the system of Gribeauval, which had served its time, was further improved upon. The *matériel* adopted in 1827 consisted of 12-pounder and 8-pounder guns, and 6-inch and 24-pounder howitzers. A six gun battery was composed of either four 12-pounders and two 6-inch howitzers, or four 8-pounders and two 24-pounder howitzers. The carriages and ammunition waggons were also improved, so that the detachments could be mounted on them, and the mobility thus much increased. A new mountain artillery equipment was also adopted; a powerful 12-pounder howitzer, but weighing only 220 lbs., was introduced, the carriage and ammunition boxes being carried on mules; and this equipment proved very serviceable in the Algerian campaigns. In 1852 Napoleon III., when president of the Republic, did much to simplify the *matériel*, and introduced a 12-pounder shell gun, intended to fire solid shot or shrapnel shell. Louis Napoleon had always made artillery a special subject of study; and the great work on artillery commenced and mainly carried out by him is a standard work on the subject. In 1858 rifled guns, 12-pounders and 4-pounders, were adopted in the French service, and used with great effect against the Austrians in the Italian campaign of the following year. Since the war of 1870-71, where the French artillery proved itself markedly inferior both in numbers, power, and handling to that of their adversaries, the French have been actively engaged in carrying on experiments, with a view to the introduction of a superior weapon, and have further increased their force of artillery by 120 batteries.

Prussia. At the commencement of the 19th century the Prussian artillery was rather powerful than mobile, the field artillery counting 216 12-pounders, 96 heavy 6-pounders, and only 120 light 6-pounders. After the disasters of 1806–7 this defect was remedied; and in 1816, when a further reorganisation took place, the ninety-six guns allotted to each army corps were in the proportion of three heavy to eight light. The horse artillery numbered twenty batteries in 1809, and twenty-seven in 1816, and for many years formed the bulk of the reserve artillery. The *personnel* of the Prussian artillery has developed enormously during the 19th century. In 1808 it formed three brigades, each consisting of six field and two horse artillery batteries. In 1814 it was increased to nine brigades, each composed of twelve field and three horse artillery batteries, besides a proportion of garrison artillery and artificers, and corresponding to one of the permanent army corps of the Prussian army. It was with this organisation but slightly modified that Prussia undertook the wars of 1864 and 1866. In the latter war the Prussian artillery did not shine so much as its Austrian adversary; and deficiencies were brought to light which were carefully remedied in the few years of peace which followed. In 1867 an addition was made of three Prussian and one Saxon regiment of field artillery, with four divisions of garrison artillery, consequent on the incorporation of Schleswig-Holstein, Hanover, Nassau, &c., and the formation of three new army corps from these provinces. It was with this establishment that the war of 1870–71 commenced. The South German forces contributed four regiments of Bavarian artillery and twenty-eight batteries of Würtemberg, Baden, and Hessian artillery; and altogether seventeen regiments of field and nine of garrison artillery took part, or were effective for service, in that war. In 1872 the German artillery was reorganised, the field artillery of each army corps being augmented to seventeen batteries, and divided into two regiments.

Austria. Similar progress was made by the other great European powers during this century. The Austrian artillery has always been pre-eminent both in the excellence of its *matériel* and in tactical handling on the field. In 1859 rifled guns were introduced; and in 1861 gun-cotton was substituted for gunpowder, but was soon afterwards abandoned. In the unsuccessful war of 1866 her artillery especially distinguished itself by its gallantry and devotion, and showed itself decidedly superior to that of her adversary. A considerable development of her artillery has taken place within the last few years, which will be treated of further on. Russia, which specially distinguished itself in the Napoleonic wars by the power and good service of her artillery, has continued to devote the same attention to it. In 1861 she adopted the French system of rifled guns, but after the German war of 1866 she abandoned it for the breech-loading system of Prussia, and has armed her field artillery mainly from the manufactory of Krupp at Essen. Of late years Russia has shown the greatest activity in all matters connected with artillery; the re-equipment of her siege, garrison, and coast artillery has been energetically proceeded with, and her fortresses re-armed; more than 1000 rifled guns having been supplied and mounted in the years 1869-70. Her field artillery has also been increased from three to four batteries per division, and thirty-eight batteries of mitrailleuses added. Russia.

Indian artillery. To complete this historical portion of the subject some brief notice is necessary of the Indian artillery, which springing from the Royal Artillery in 1748 returned to it again in 1862, after a varied but glorious career. The company of Royal Artillery sent to the East Indies in 1748 formed the nucleus from which three companies of regular artillery, one for each presidency, were raised in 1749. Five more companies were sent out between that and 1756; and on the reorganisation of the Indian army by Clive in 1765, the greater part of the Royal Artillery then serving there volunteered for, and was incorporated with, the Indian army, thus forming the basis upon which were formed the three corps of Bengal, Madras, and Bombay artillery. Its early days were passed in difficulties and comparative obscurity; it was recruited largely from the navy or merchant service, and many of the terms still in use, such as "lascar" (native assistant-gunner), were drawn from that service. Its officers, as a rule, were utterly without technical training. By degrees, however, educated officers were obtained from the Royal Artillery, and both *matériel*

[1] See below under "Tactics."

and organisation were improved, the changes following those adopted in England though somewhat tardily. Up to the end of the 18th century, however, bullocks were alone used for artillery draught, attached to the carriages by yokes and traces of raw hide; and in the earlier wars the ammunition was carried on the heads of lascars. The artillery developed rapidly, as our Indian possessions and Indian armies increased, and bore a constantly increasing share in our triumphs in that country. Early in the 19th century it numbered three horse brigades, and seven European and three native battalions. In 1845 the Afghan and Gwalior campaigns led to improvements in this branch; and in the Sikh wars the artillery was at last placed in its proper position. In 1857 it had attained its maximum strength, and numbered no less than sixty-five European and sixty-six native troops and batteries, with a total of 524 field guns. Its last and most brilliant services as a separate body were rendered in the great Sepoy mutiny, and in 1862 it was amalgamated with the Royal Artillery.

Organisation, Administration, and Matériel.

Modern artillery is broadly divided into field, siege, and garrison; and field artillery, again, is divided into mountain, horse, field (or foot),[1] and position artillery. The battery is essentially the unit of artillery organisation, both tactical and administrative; and brigades or regiments are formed by combining a number of batteries for convenience of administration.

Field artillery. A battery of field artillery comprises three elements: viz., *matériel*—guns, carriages, ammunition, and stores; *personnel*—officers and non-commissioned officers, gunners to serve, drivers to groom and drive, and artificers; and *transport*—horses, mules, elephants, oxen, &c. The number of guns in a battery varies from four to eight. Mountain and position batteries have usually four or six, field and horse batteries six or eight guns each. In England, France, and Prussia, there are six guns to a field or horse battery; while Russian and Austrian batteries have eight guns. The latter number seems to possess decided advantages. It admits of more convenient division; and the half-battery of four guns is a small but convenient battery for any particular service. In England, where the battery is divided into three divisions of two guns each, the centre division has to be divided to form half-batteries. Moreover, the larger the unit consistent with tactical considerations, the fewer will be the relative number of non-fighting carriages, such as forges, &c.

Usually the guns in a battery are all of one class, but sometimes what are termed *mixed* batteries are formed. Thus, until recently a field battery consisted of five guns and one howitzer, or four guns and two howitzers. These mixed batteries were supposed to have an advantage over those of guns alone, in that they commanded every kind of fire, and were adapted to every variety of circumstance. There was, however, a serious objection in the fact, that the differences between the gun and howitzer were so great in range and employment, that the fire of one must usually be comparatively neutralised; and the universal use of shell guns has now practically abolished mixed batteries.

The carriages which accompany a battery include (besides gun-carriages and limbers) ammunition waggons, store and provision carts or waggons, and forge waggons. The number of ammunition waggons depends upon the amount of ammunition which it is considered necessary for a battery to take with it in action—an important question, upon which there is considerable diversity of opinion. The greater the amount of ammunition a battery carries with it, the more independent it is; on the other hand, every additional waggon makes the battery more cumbrous, and lengthens out the column of march,—a serious consideration at all times, and especially in the case of artillery moving with the advanced guard of an army. The proportion of ammunition to be carried must be based on past experience. At the battle of Lützen, 1813, the French fired 220 rounds per gun, and on this they based their estimate. But in all the great battles of the Franco-German war of 1870–71 the maximum expenditure was 94 rounds per gun; at Vionville and at many of the great engagements not more than half this average was reached. The accumulation of waggons leads to batteries leaving a large part of their ammunition waggons at some convenient point under shelter when going into action; and the tendency now is to reduce the amount of ammunition with the battery in order to obtain the greatest possible mobility, and provide against any failure of ammunition by a more efficient system of ammunition columns. In former days batteries were further hampered by having to carry the reserve of small-arm ammunition for the infantry and cavalry. This system was said to be advantageous, in that the infantry knew at once where they could obtain their ammunition, but its disadvantages were numerous, as it seriously encumbered the artillery; and, moreover, with the new tactics of long-ranging guns, the artillery, instead of closely accompanying the infantry, will often remain at a considerable distance in rear, while the infantry is advancing. The reserve of small-arm ammunition is therefore now carried by special ammunition columns.

The distinction between horse and field or foot artillery is another question at present engaging attention. Horse artillery was created to compete with cavalry in rapidity of motion, and for this purpose every man was mounted; while field batteries were supposed to accompany the infantry, and their pace under ordinary circumstances to be limited to that of a man on foot. Under the new conditions of improved fire-arms, the dash of horse artillery has no longer its former value, while more mobility and more independence of action is required for the field batteries. It is therefore held by many that there should be only two classes of artillery: horse, or very mobile field artillery, and position batteries of heavy guns.

The organisation and interior economy of a battery is much the same in all field artillery. In England the command is held by a major. Upon the commanding officer depends to a great extent the efficiency of the battery in peace and in war. He should be not only well versed in stable management and the ordinary routine of his duties, but he should be acquainted with the *matériel* with which he has to deal, and be a practical gunner; and further, besides the tactics of his own arm, he should understand the combined tactics of the other arms in order to appreciate intelligently what is required of artillery in modern warfare. The second in command is a captain. The battery is divided into three divisions of two guns each, each under a subaltern officer, who is responsible for everything connected with his division,—men, horses, guns, carriages, ammunition, and stores. Each division, again, consists of two subdivisions, each comprising one gun and ammunition waggon, with its quota of men and horses; and at the head of each is the No. 1 of the gun detachment,—usually a sergeant,—who is immediately responsible to the divisional officer for his subdivision. The No. 1 is technically the head of the gun detachment of nine gunners, and his duties in the field are to lay and command the gun.

Rockets and *Mitrailleurs* are generally associated with

[1] The term *field* artillery has a general and a particular sense. In the former it applies to all kinds of artillery which accompany an army on the field of battle; in the latter it is confined to that branch (in some armies called *foot* artillery) which is supposed ordinarily to move with infantry, as distinguished from the lighter *horse* artillery and the heavier *position* artillery.

field artillery in organisation, but will be found treated of under their own titles. Rockets were applied to warlike purposes by Sir W. Congreve about 1804. They were used in 1809 in the Walcheren expedition, and with great success at Leipsic in 1813, but have since fallen somewhat into discredit on account of the danger of the service and their inaccuracy of flight. They are, however, still used for mountain and forest warfare against savage tribes, as in Abyssinia, in 1868, and in Ashantee, in 1874; and are very valuable for this purpose, from their extreme portability and their moral effect. The rockets now used are Hale's; they have no stick. They are carried in special rocket carriages when required. The rocket troop of horse artillery did excellent service in its day, but has long been abolished; for some time a rocket section was attached to every battery, but this has also been done away with. Mitrailleurs are extensively used by some of the Continental powers, especially the French and Russians, but have not yet been adopted as part of the British field artillery. The Germans oppose them on the ground that they are not equal to the guns, which they to a certain extent supersede. A Russian infantry division has one, and a French division one battery of mitrailleurs attached to it.

Siege and garrison artillery.

Siege and Garrison Artillery.—Siege and garrison artillery have not usually the complete and permanent organisation that distinguishes field artillery. In India and some other countries permanent siege trains are maintained; but usually the *matériel* is kept in store, and the *personnel* and transport are supplied from other sources according to requirement. In garrison artillery, the guns mounted on fortresses and batteries, or stored in arsenals for the purpose, furnish the *matériel*, and the battalions or companies of garrison artillery the *personnel*.

England.

In giving a brief account of the artillery services of different nations at the present time, we begin with that of Great Britain.

Mountain batteries.

(*a.*) *Mountain Batteries* have for many years past been used in India, where the details have from time to time been changed by the light of experience. In England no batteries of this kind are maintained, though the *matériel* would be forthcoming and the *personnel* would be supplied from the garrison artillery. In 1868 two batteries were organised for the Abyssinian expedition, each composed of six 7-pounder M.L.R.[1] guns, with steel carriages, ammunition boxes, rockets, forge, &c. The gun now adopted is a 7-pounder steel M.L.R. gun, of 3 in. calibre and 200 ℔ weight. The carriages are entirely of iron, the axletree consisting of a stout bar of wrought-iron, the brackets, of single plate, being housed directly across it. The projectiles are common shell, double shell, sharpnel, and case; the double shell is fired at high angles, with a reduced charge, and a modified form of vertical fire is thus secured, which is very useful in hill campaigns. In Abyssinia the guns were carried on the backs of mules, transversely supported on iron saddles or cradles. It is generally considered more expedient, however, to carry the guns lengthwise. The carriage is distributed between two mules, one carrying the bed and trail, and the other the wheels. The ammunition is carried in boxes, a pair to each mule. Mules are also provided for a small forge, tools, stores, &c.

In India mountain batteries are of two kinds; European and native, both officered from the Royal Artillery. There are two European batteries stationed in the Himalayas. The detail of each is 6 officers, 23 non-commissioned officers and trumpeters, 1 collar maker, 70 gunners; total, 100 Europeans, with 119 native drivers, besides a native establishment of muleteers for baggage mules, grass cutters, artificers, &c., and 182 mules. There are two native mountain batteries in Bengal, and two in Scinde; and it is intended to increase the mountain batteries of India by turning certain native field batteries attached to the local Panjab Frontier Force into mountain batteries.

Horse batteries.

(*b.*) *Horse Batteries.*—Horse artillery batteries differ from field batteries in possessing a lighter equipment, and in having the detachments of gunners to serve the guns mounted on horses. They are armed with six 9-pounder M.L.R. guns of wrought-iron, with tempered steel tube weighing 6 cwt.[2] The *personnel* of a horse artillery battery at home is as follows:—

	Peace Establishment.	War Establishment.
Officers	5	5
N.-C. Officers and Trumpeters	20	22
Artificers	7	10
Gunners	70	70
Drivers	56	70
Horses (exclusive of officers' chargers) riding	54	62
Horses (exclusive of officers' chargers) draught	78	102

In India a battery has, further, a large non-combatant native establishment, as 23 subordinate medical and hospital attendants, and no less than 339 artificers and followers of various kinds.

The detail of guns and carriages is as follows,—6 guns and carriages, 6 ammunition waggons, 1 forge, 1 store, 1 general service waggon, and 1 store cart. The construction of our carriages is very solid, excessively so in the opinion of many, as mobility is sacrificed to gain strength; but this is partly caused by the fact that English carriages must be so constructed as to endure all extremes of climate. The gun-carriage for horse (and field) artillery is of wrought-iron.

The ammunition waggons are built on a framework of wrought-iron, with wrought-iron perches and wooden ammunition boxes. The projectiles are common and shrapnel shell, and case shot. Each limber has two boxes, and the body of the ammunition waggon four; each box contains a centre compartment, with 18 filled cartridges, two compartments front and rear, each with 6 shrapnel shells, and two side compartments containing 3 common shells and fuses in proportion. The ammunition carried is 4 case shot in the axletree boxes of the gun-carriage, 12 common shell, 24 shrapnel in the limber of the gun, and 36 common shell and 72 shrapnel in the ammunition waggons. A total of 148 rounds is thus carried by each gun with its ammunition waggon.

The stores for horse and field batteries are numerous, consisting of camp equipment, entrenching tools, harness and saddlery, artificers' tools, ordnance stores, and miscellaneous articles, the details of which will be found in the regulation hand-books and equipment tables. These are packed and carried on the different carriages of the battery. Thus the gun-limber carries drag-ropes and axe in front, and other implements, such as spade, shovel, pick-axe, at the side of the boxes, or underneath. A centre box on the limber contains time and percussion fuzes and friction tubes. On the lids of the boxes inside are carried various fuze implements, and a camp kettle and two leather buckets are carried under the limber-boxes. Traversing handspikes and sponges are carried on the gun-carriage itself, and in the axletree boxes, besides the case shot, linch-pins, drag-washers, gun-spikes, &c.

The waggon is packed much in the same way, but two camp kettles are carried under the body, and a spare wheel in front, three picket posts are carried on each side of the body, and under each alternate waggon of the battery a spare shaft or axletree. The tents are packed between the

[1] The abbreviations M.L.R. and B.L.R., for "muzzle loading rifled" and "breech loading rifled" respectively, are used in the technical description of guns.

[2] In India a few batteries are still armed with guns of old patterns.

ammunition boxes, and the many other stores distributed in various ways throughout the battery.

Each carriage in a horse artillery battery has six horses, except the general service waggon and store cart, which have only four. The horses are teamed in pairs,—lead, centre, and wheel,—the drivers mounted on the near horses. The off horse of the wheel is in the shafts. Much controversy has been raised as to the respective merits of "shafts" or "pole;" the latter was in use in India for many years, and is still generally used by Continental powers. The balance of advantage seems to lie on the side of shafts, but it requires a very powerful horse for the off wheeler, on whom so much is thrown. The harness is strong and fairly simple. The off horses have pads upon which the valises containing the drivers' kits are carried. Picket ropes and posts are carried on the waggons, and each mounted man has a head rope and a forage cord, which may be used as a heel rope, a peg and leather shackle being carried for it.

(*c.*) *Field Batteries* differ from horse artillery in that they have a heavier armament, and the gunners are not mounted. The guns now in use are—(1) 9-pounder M.L.R. gun of $8\frac{1}{2}$ cwt., (2) 12-pounder B.L.R. Armstrong gun of 8 cwt., (3) 16-pounder M.L.R. gun of 12 cwt. No. 2 has, however, been superseded in England, and will erelong become obsolete in India also, where the whole of the field artillery is being armed with the 9-pounder M.L.R. The 16-pounder is a most powerful gun, probably the most powerful field gun in Europe, but is heavier than the corresponding guns in Continental armies, and some consider that its weight is inconsistent with sufficient mobility.

The *personnel* of a field battery is as follows:—

	Peace Establishment.	War Establishment.	Indian Establishment.
Officers	5	5	5
N.-C. Officers	19	20	20
Artificers	7	9	5
Gunners and Trumpeters	68	87	78
Drivers	61	73	54
Horses	88	154	110

The peace establishment, however, is variable. In India a field battery has, further, a native establishment of hospital attendants, lascars, grass-cutters, artificers, &c., and amounting in all to 247.

A field battery has 6 guns and carriages, 6 ammunition waggons, 1 forge, 1 store, and 1 general service waggon—total, 15. In war time the 6 ammunition waggons (known as the second line of waggons) form the nucleus of the ammunition reserve. In India the second line of waggons are kept in readiness in the arsenals, and when taken into the field are drawn by bullocks. The gun-carriages are of wrought-iron, similar in construction to those of horse artillery. The obstacle to the rapid movement of field artillery has always been, that no means were provided for carrying *with* the gun the gunners required to serve it, as the limber could at most only accommodate three men. In India the constant necessity for rapid movement had caused the adoption of axletree seats, by which two more gunners could be mounted, one on each side of the gun, and saddles were also provided for the lead and centre horses of the gun team, so that, with the mounted non-commissioned officer, seven men would be at hand to serve the gun, independently of those mounted on the waggons. The axletree seats are generally used on the Continent, and have recently been adopted in England for field batteries.

The projectiles for the M.L.R. guns are common shell, shrapnel, and case; the first used against earthworks, buildings, &c., the second against troops, and the third at close quarters. The fuzes used are percussion and wood time fuzes. The amount of ammunition carried with the 9-pounder M.L.R. gun, and manner of carrying it, are the same as in the horse artillery. With the 16-pounder M.L.R. field batteries, the arrangement of the ammunition and the packing of the boxes and stores are similar, but the number of rounds carried is less. The near limber box of both gun and waggon contains 7 common and 5 shrapnel shells, the off one 5 common and 7 sharpnel, while the front waggon boxes contain each 5 common and 7 shrapnel shells, and the rear boxes 12 shrapnel; so that, with four rounds of case in the axletree boxes, the gun and waggon carry 34 common shell, 62 shrapnel, and 4 case, or 100 rounds altogether. In India the ammunition stores, &c., are similarly packed, but the camp equipment being larger is separately carried on camels provided for the purpose.

Field artillery has been *carried* on elephants in India, and cradles or saddles are kept up there for the purpose in case of need; and has also been transported by *sleighs*, as in Canada. The sleigh is a platform placed on runners 16 inches high and 3 feet broad. A description of the sleigh-carriages and the exercise with them is given in the *Hand-book for Field Service*.

Position batteries.

(*d.*) *Position Batteries*,—a heavy field artillery, capable of movement, but not required to move fast, or to change position frequently, and used in the defence of special important points on a battle-field, entrenchments, &c. No manned batteries of this description are kept up in England, but the *matériel* is kept in store, and the *personnel* would be furnished from the garrison and field artillery. The guns at present used are 40-pounder B.L.R. Armstrong guns, 40-pounder M.L.R., and 25-pounder M.L.R. guns. The carriages are of angle iron, with bracket trails, and of great strength; the projectiles are common and shrapnel shell, and case. The detail for a battery is as follows,—4 guns and carriages, 4 ammunition waggons, 1 forge, 1 general service, 1 platform, 1 store waggon, and 1 store cart. The guns are drawn by 12 horses, harnessed four abreast; and as it is intended that the horses shall be furnished from the country if possible, the batteries have been specially fitted for the attachment of farmers' horses.

In India position artillery is maintained in the form of "heavy field batteries," some being armed with 40-pounder Armstrong guns and 8-inch mortars, others still with the old smooth-bore guns. The guns are dragged by elephants, two for each gun, one in the shafts and the other as leader; the mortars and ammunition waggons by oxen. Elephants are dangerous under fire, and, therefore, their place is then taken by bullocks, of which ten pair are required for a gun.

Siege artillery.

(*e.*) *Siege Artillery.*—There is no special organisation of siege artillery in England in time of peace. The *matériel* is kept in store, and the *personnel* and transport are furnished according to the requirements of the particular service. The new M.L.R. wrought-iron guns, 40 and 64-pounders of 35 and 64 cwt. respectively, will probably form part of any future siege train, and with these will be associated 10-inch and 8-inch M.L.R. howitzers, and $5\frac{1}{2}$ inch and 10-inch mortars, or, perhaps, a rifled mortar. The *personnel* would be supplied from the garrison artillery, a battery of which at war strength would form a siege train battery. The transport might be specially furnished or supplied from the country in which operations were to be conducted.

The proportions of guns, &c., in a British siege train would be approximately—

55	64-pounder M.L.R. guns.
20	40-pounder " "
30	8-inch M.L.R. howitzers.
105	

To these would probably be added rifled and smooth bore mortars according to circumstances.

The proportion of ammunition must vary with the nature of the siege, but as a standard a detail has been fixed, which is given at length in the *Revised Army Regulations of* 1870.

The number of men required is calculated for three reliefs, or 30 men per gun, 15 per large mortar, and 9 per small mortar, with a reserve. A brigade of garrison artillery on war strength, numbering 51 officers, 135 non-commissioned officers and trumpeters, and 800 gunners, is held to be sufficient to man a siege train of 35 pieces.

The carriages employed are gun-carriages and limbers, howitzer and mortar-carriages, platform waggons, general service waggon, siege waggon, store waggon, sling waggon and cart, hand and trench carts. The carriages are generally of the block trail pattern, and, except that they are stronger, are similar in construction to the travelling carriages for field service. The new siege limber is of universal pattern, and similar to the field limber in construction. The mortar-carriages consist of a bed with an axletree mounted on two wheels, and with a perch for limbering up to a limber for travelling. The platform waggon is composed of a fore and hind carriage, with a platform over them for carrying guns and mortars. The general service waggon consists of a fore and hind carriage with body over them, covered with waterproof canvas. The siege waggon is merely the general service waggon strengthened and fitted so as to transport shot and shell. The store waggon consists of a body and limber, and will contain spare stores and materials, and necessary tools. The sling waggon is composed of a body and limber, and fitted with windlass arrangement so that guns can be slung up underneath. In the heavier pieces iron sling waggons are used. Considerable improvements will probably be made in siege carriages so as to admit of the abolition of embrasures and of the gun being fired over the parapet.

In India siege trains are kept in readiness in arsenals, and the transport, which is composed of bullocks, is to a large extent also maintained. These siege trains have been hitherto composed of old smooth-bore guns, but these will be replaced by rifled guns. There are 16 such trains, with a total of 400 or 500 pieces. The *personnel* would be supplied from the garrison artillery and the native establishment in the arsenals.

The duties of the siege trains, the position of parks and batteries, &c., rather relate to the conduct of sieges, and do not therefore fall within the scope of the present article.

Garrison artillery.

(*f*.) *Garrison Artillery*.—The garrison battery consists only of *personnel*, the *matériel* used being part of the defences or fortress in which this branch of the artillery is employed. The establishment of a battery is as follows:—

	Peace.	War.	India.
Officers	4	4	5
N.-C. Officers	16	16	16
Gunners and Trumpeters	80 to 120	142	72

An Indian battery, further, has a native establishment of 30 hospital attendants, followers, &c. The care and preservation of the ordnance in fortresses and batteries, with all the complicated appliances and scientific constructions of modern artillery *matériel*, and of the carriages, stores, and ammunition, devolve upon the garrison artillery in peace time.

For fortress defence large numbers of smooth-bore 68, 32, and 24-pounders, and 8 and 10-inch shell guns, are still mounted. The general tendency, however, is to replace these with rifled guns of calibre suited to the importance and object of the work, while the mitrailleur or Gatling gun will probably be used in flanks and for the defence of ditches. Large numbers of 7-inch or 110-pounder B.L.R. Armstrong guns have been mounted since 1862. The M.L.R. guns are 7, 8, 9, 10, 11, and 12-inch, the latter weighing 35 tons. The projectiles of these are common, shrapnel, and Palliser shell, case, and Palliser cored shot, and attain the extraordinary weight of 690 lb. An 81-ton gun is now (1875) in process of construction, and is calculated to throw a shell of 1600 lb.

The old smooth-bore garrison carriages are of wood, with various arrangements and platforms for traversing. The new carriages for the large M.L.R. guns are of wrought-iron, with hydraulic buffer arrangements. The Moncrieff carriage and system, by which the gun is loaded and laid in a gun pit, raised by a counterweight, and released again, descending after firing by the regulated power of the recoil, will probably be extensively employed in coast defences; and it is probable that still further improvements will be made in the carriages for the immense ordnance now used.

General Organisation.—The whole of the British artillery forms one regiment, the "Royal Regiment of Artillery," numbering 1414 officers and 33,688 men, and distributed in 216 batteries of horse, field, and garrison artillery. For purposes of administration a unit higher than the battery is adopted, called the *brigade*. Each brigade has its own staff of colonel-commandant, 4 lieutenant-colonels, adjutant, quarter-master, &c. The batteries of the brigades are, as far as possible, kept in the same part of the country where the headquarters are serving. There are 6 brigades of horse artillery, 12 of field artillery, 13 of garrison artillery, and the "coast brigade;" their detail and distribution will be found in the account of the British army (see Army, p. 578). Besides the brigade organisation, there is another which may be termed the territorial system, or district commands, having reference especially to local duties, stationary *matériel*, such as guns mounted on forts and batteries, &c. These artillery districts correspond generally to the army districts, and have at their head a colonel on the staff, or other officer commanding the artillery district. In the United Kingdom there are also artillery sub-districts, under lieutenant-colonels, who are invested with the commands of the auxiliary and reserve force artillery of the sub-district. The highest administration of the Royal Artillery is conducted at the War Office, in the department of the Commander-in-Chief,—a deputy-adjutant-general of artillery, with assistants, being attached for that purpose to the adjutant-general's division. An inspector-general of artillery is charged with special artillery inspections in the United Kingdom, and also inspects the *matériel* and munitions of war in the hands of the artillery. The department of the director of artillery and stores at the War Office is a branch of the Ordnance Department (see Army, pp. 573, 582), and deals with all matters relating to armaments, stores, and munitions not in artillery charge, and superintends the manufacture of warlike stores and the scientific experiments which have to be constantly made. In India the administration is not dissimilar, a deputy-adjutant-general and inspector-general of artillery performing duties analogous to those of the similar officials in England, while the director of artillery is represented by an inspector-general of ordnance and magazines.

Although Woolwich is no longer the official headquarters of the artillery it is the chief artillery station, and continues to be that to which officers and men practically look as their headquarters. The mess and band of the regiment are permanently maintained there; and a large number of batteries, including the greater part of the depôt brigade, are always stationed there, and it further contains most of the great artillery establishments, both manufacturing and instructional.

For an account of the manufacturing establishment see Arsenal, p. 633, and for the scientific and educational establishments see Army, p. 586.

Proportion of guns to men.

Unlike Continental nations, England has no permanently organised army corps and divisions, and, consequently, no combinations of artillery with the other arms. Her colonial possessions, and the vast extent of her Indian empire, raise almost insurmountable obstacles to any organisation which shall fulfil equally the conditions of peace and war, and have necessitated a distribution of the artillery on principles other than those which obtain in the more facile systems of Continental armies. The proportion of guns to men at present existing is 2·45 per 1000 men; the grand total of guns for field service,—including field, mountain, and position batteries—being 784, while the total strength of troops, British and native, is 320,000. This proportion is somewhat under that now generally accepted, viz., 3 guns per 1000 men. The proportion of guns to men has varied with the circumstances of the age and country. During the 18th century the proportion was usually 3 per 1000, though Frederick at one time raised it to over 5 per 1000. In the earlier wars of the French Republic the allies increased the proportion unduly; and Napoleon, whose rapid tactics did not admit of his hampering his army with heavy trains, reduced it again. He advocated 2 guns per 1000 with old and tried troops, but 3 guns per 1000 with the usual composition of an army; and in his later campaigns, when his armies consisted almost entirely of recruits, he even exceeded this proportion. In the Crimean war, and in 1859, the Russians and Austrians increased this ratio considerably, but the great increase to the strength of armies which took place between 1866 and 1871 led to a comparative decrease of artillery, and the Germans have now rather less than 3 per 1000. It must be remembered, however, that the actual proportion on service is always in excess of the nominal one, often considerably so, as the guns are not reduced by the wear and tear of the campaign as the *personnel* of an army is; a battalion is soon reduced from 1000 to 500 men, but a battery always retains its six guns. In the great American war of 1861–65, the proportion of guns at first was nearly 6 per 1000, but towards the end was reduced to little over 1 per 1000, showing how the proportion is affected by the nature of the country which is the scene of operations.

Important questions connected with the organisation of the British artillery are now giving rise to discussion, and will probably be solved shortly; the two principal ones being the breaking up of the huge, overgrown "regiment" of artillery into smaller units, and the separation of the field from the garrison artillery. The appellation "regiment," for a force of 35,000 men and officers, is manifestly a misnomer, and the continuance of the present system is upheld principally on what may be termed "sentimental" grounds,—unwillingness to break old ties and uproot traditions, and fears that the *esprit-de-corps* of the service might suffer in the change. The separation of the field from the garrison artillery has often been advocated on the grounds of the essentially different nature of the two services, and the fact that the men and *matériel* are already separate, the officers alone being transferred from one branch to the other. The full discussion of the proposed changes does not fall within the province of this article.

France.

The organisation of the French artillery has been completely changed by recent regulations. Previous to the Franco-German war of 1870–71, it consisted of 1 horse artillery and 1 field artillery regiment of the guard, 4 horse artillery and 12 field artillery regiments of the line, with garrison artillery, making up 19 regiments. The horse artillery regiments consisted of 8 batteries of 6 guns each, and the field artillery regiments of 12 batteries. Only 8 out of the 12 were mobilised during war, 4 remaining as *batteries de sortie* for garrison service. The number of field guns available was 984. This number of guns could not be put in the field at once, as 58,000 men and 39,000 horses were required, while in peace time only 34,000 men and 16,000 horses were kept up. The guns in the service were a 9-pounder (shell) mountain gun of 2 cwt., 9-pounder of 6½ cwt. for field artillery (*canon de* 4), 16-pounder of 11½ cwt. (*canon de* 8), 25-pounder of 12 cwt. for position artillery (*canon de* 12), and 50-pounder of 40 cwt. (*canon de* 24) for siege purposes. These were of bronze, and rifled on the La Hitte system. In naval service B.L.R. guns of cast-iron, strengthened by rings, have been employed, ranging from 70 to 300-pounders. The field guns fired studded projectiles, shell, shrapnel, and case; and the heavy guns heavy elongated projectiles of similar kinds.

In accordance with the recent regulations, each of the 18 French army corps has a brigade of artillery attached to it, consisting of 2 regiments, 1 of divisional, the other of corps artillery. The divisional regiment consists of 8 field batteries and 1 depôt battery; the corps regiment, of 3 horse artillery batteries (1 of which is attached to the cavalry in time of war), 9 field batteries (1 of which is utilised for service in Algeria), and 1 depôt battery. Each brigade has besides 4 dismounted batteries for garrison service, and 4 companies of drivers for ammunition columns. An army corps has, therefore, 4 batteries attached to each of its divisions, and employs 10 batteries in addition as its corps or, as it was formerly called, reserve artillery. The war strength of each battery is 5 officers and 168 men. The field guns in use are the 15 and 10-pounder bronze B.L.R. Reffye guns (*canons de 5 et de 7*). (See GUNS AND GUNNERY.)

Germany.

The general organisation and distribution of the German artillery will be found under ARMY (p. 597). To each territorial army corps is attached a brigade of artillery, consisting of 2 regiments of field artillery and a regiment, or portion of a regiment, of garrison artillery. The first *field* regiment or corps artillery consists of 2 field divisions of 3 field batteries each, and one horse artillery division of 3 batteries. The second field regiment or divisional artillery consists of 2 divisions, each of 4 field batteries. The field guns are the 9-centimètre B.L.R. gun, firing a shell of 15½ ℔ weight, used by the field batteries, and the 8-centimètre B.L.R. gun, firing a projectile weighing 11 ℔, with which the horse artillery is armed. These guns are of cast steel, with polygrooved rifling and wedge breech action (*système de Krupp*). Each battery has 16 carriages, viz., 6 guns and carriages, 6 ammunition waggons, 3 provision and store waggons, and 1 forge waggon. The gun-carriages are double cheeked, and made of plate iron. The ammunition waggon carries one large box opening to the rear. The projectiles are a common shell of novel construction, case, and shrapnel—the latter only lately introduced. The following ammunition is carried per gun:—

Field artillery.

	Ammunition.	Gun Limber.	Waggon Limber.	Waggon Body.	Total per Gun.
8-cent. gun	Common Shell	24	24	32	80
	Shrapnel	12	12	16	40
	Case	3	2	...	5
	Total	39	38	48	125
9-cent. gun	Common Shell	20	20	30	70
	Shrapnel	10	10	15	35
	Case	3	2	...	5
	Total	33	32	45	110

The artillery ammunition columns have 25 waggons each, and provide a first reserve of about 125 rounds per gun. The infantry columns have 24 small-arm ammunition waggons.

The following table gives the *personnel* and transport of a battery or ammunition column on war establishment:—

	Batteries.			Ammunition Columns.	
	Horse.	Field.		Artillery.	Infantry.
		8-centm.	9-centm.		
Commanding officer	1	1	1	1	1
Subalterns	4	4	4	..	..
Officers of ammunition columns	...	...	...	2	2
Laboratory conductor (officer)	..	.	...	1	1
Quartermaster	1	1	1	1	1
Ensign (aspirant to rank of officer)	1	1	1	.	
Non-Commissioned officers	12	12	12	12	12
Trumpeters	2	2	2	2	2
Gunners	42	42	48	8	8
Drivers	49	60	60	23	26
Spare men	38	23	23	37	34
Corporals		..	.	3	3
Hospital orderly	1	1	1	1	1
Collarmakers and Saddlers	2	1	1	1	1
Soldiers of the transport train (including officers' servants)	5	5	5	80	84
Total	158	153	159	172	176
Horses: Officers'	15	7	7	4	4
Horses: Draught	92	92	92	132	140
Horses: Riding	100	16	16	22	22
Horses: Spare	6	8	10	8	8
Total	213	123	125	166	174

Siege artillery. For *siege* purposes the Germans use the 12-centimètre (4·68 inch) bronze gun, firing a 29-lb shell, and steel and bronze guns of 15 centimètres (6·85 inch) calibre, firing a 54-lb shell. The mortars used are the 8-inch rifled, and the smooth-bore 15-centimètre. The usual composition of a siege train is 400 guns, viz.:—

320 rifled guns:
- 40 of 9-cm. (bronze).
- 120 of 12-cm. (bronze).
- 120 of 15-cm. (steel), short
- 40 of 15-cm. (steel), long.

40 rifled 21-cm. mortars, 40 smooth-bore 15-cm. mortars,—

besides 150 rifled wall pieces.

A 21-cm. shell gun and a 28-cm. rifled mortar are likely to be added to this list soon. Each gun has 508 rounds of ammunition ready for immediate service.

The siege trains are 2 in number, and in time of war have 16 ammunition columns attached to each. These columns consist of 46 ammunition waggons, 6 open waggons, a forge, and some baggage and forage carts. Each waggon is adapted for draught for either 4 or 6 horses.

Garrison artillery. The *garrison* guns are the 12-centimètre gun in cast-iron and bronze, 15-centimètre, 23-centimètre (9-inch) cast-iron howitzer and heavy guns for garrison, coast, and naval purposes, ranging from 7-inch to 13-inch calibre. The Prussian artillery is breech-loading, and three systems are employed in the closing of the breech, viz., that of Wahrendorf, or the "piston" arrangement (*Kolbenverschluss*)—that of Kreiner, or the "wedge" system (*Keilverschluss*)—and the Krupp system, or cylindro-prismatic wedge (*Rundkeilverschluss*). The first dates from 1861; the second system has been applied to land guns since 1864; the third is, in slightly varying forms, applied to all the most recently manufactured guns. The siege carriages have a peculiar arrangement of iron supports on the cheeks, by means of which the gun is enabled to fire over the parapet. The foot or garrison artillery has recently been reorganised into 30 battalions, counting 122 batteries or companies. The number of regiments is 19, but the number of battalions in a regiment varies. The garrison artillery is separated from the field artillery, and is specially attached to the army territorial commands, and officers can only be transferred from one branch to the other by special permission.

Austria. The Austrian artillery is divided into field, garrison, and technical artillery.

Field artillery. The *field artillery* consists of 13 regiments, having their permanent headquarters in Prague, Olmütz, Komorn, Josephstadt, Pesth (2), Grätz, Vienna (2), Lemberg, Neustadt, Laibach, Temesvar. Each regiment comprises six 8-pounder and four 4-pounder field batteries, three 4-pounder horse batteries, one depôt battery, and five or six ammunition columns.

Three batteries are attached to each infantry division, and three form the corps artillery, one battery being detached to the cavalry. In peace time a battery has only four guns and two ammunition waggons horsed; on war footing they have eight guns and eight waggons each drawn by four horses in the 4-pounder field batteries, and by six horses in the others. The guns are 4 and 8-pounder bronze rifled guns, having calibres of 3 and 3·9 inches, and firing 8-lb and 14-lb shell respectively.

Steel B.L. guns of the Prussian type are, however, being gradually brought into the service, the M.L. system being definitely abandoned. The carriages are double cheeked or bracketed like the Prussian. A box to hold case is fixed on the trail about halfway between the breech of the gun and the point of the trail, and adapted to form a seat. The projectiles are common shell, shrapnel, incendiary shell, and case. As in the Prussian artillery, the percussion fuze is alone used with common shell, and time fuzes for shrapnel. The peace and war establishments of batteries and ammunition columns, and the number of rounds carried, are shown in the following tables:—

	Peace Establishment.					War Establishment.						
	4-pr. Batt.			Cadres.		4-pr. Batt.		Battery.		Ammun. Cols.		
	Field.	Horse.	8-pr. Batt.	Ammun. Cols.	Depôt.	Field.	Horse.	8-pr. Batt.	Depôt.	1, 2, 3.	4.	5.

The 4-pounder batteries carry 156 rounds of ammunition per gun, the 8-pounder 128 rounds. The first ammunition reserve conveys in addition 74 rounds for each 4, and 82 for each 8-pounder. The total number of rounds for each gun is, therefore, 230 and 210 respectively.

In order to avoid dependence on foreign contractors attempts are being made to cast a *hard* bronze for field guns, and it is hoped that by employing this metal a portion of the new equipment may be furnished by the Austrian arsenals.

The war *matériel* necessary to place the batteries on a war footing is kept under charge of the field artillery, store horses being apportioned for it in the barracks of each regiment. By this system mobilisation is more quickly effected, and the *matériel* is better looked after than when stored in arsenals. Including the depôt batteries the Austrian artillery numbers 209 batteries, or 1672 horsed guns.

Garrison artillery. The *garrison artillery* consists of 12 battalions of 5 companies each (increased to 6 in war time), and one coast artillery regiment of three battalions. The garrison battalions further furnish 5 mountain batteries, increased to 6 in war time. The mountain batteries are armed with four 3-pounder rifled bronze guns, and carry 112 rounds per gun, viz., 72 common shell, 24 shrapnel, 16 case. For siege and garrison purposes the guns in use are B.L.R. 15 and 21-centimètre and 8-inch bronze guns; 8-inch and 6½-inch rifled mortars, breech-loading, have also been adopted.

Technical artillery. The *technical artillery* comprises a portion of the workmen charged with the construction and repair of guns in all arms, ammunition, artillery *matériel*, &c. The *personnel*, numbering 28 superior officers, 162 captains and lieutenants, and about 1600 men, is distributed in sixteen arsenals, established in the chief towns of the empire; in war time companies of artificers are detached from these to the parks of each army corps. Artillery officers have to serve by roster in the technical artillery.

The instruction of officers is conducted at the cadet school and at the Academy of Technical Artillery. On leaving this academy officers ordinarily pass into the garrison artillery, and after a year in this enter one of the regiments of artillery. After a second year they may be admitted, on application, to the advanced course of artillery, and after passing successful examinations are nominated as first lieutenants. Schools also exist in each regiment for the instruction of non-commissioned officers, one-year volunteers, and artillery cadets; and an autumn course of equitation, the most proficient at which are sent to the central school of equitation at Vienna, to be from thence appointed as riding-masters to the artillery regiments. For further details of Austrian artillery organisation see article ARMY, p. 606.

Russia. The Russian *matériel* is divided into mountain, field, siege and garrison, and coast artillery. The *mountain* gun is a 3-pounder bronze rifled gun of 224 ℔ weight, firing a 9-℔ projectile. For *field artillery* they use both cast steel and bronze B.L.R. guns, 4-pounder and 9-pounder, of 3·3-inch and 4-inch calibres, firing 12-℔ and 24-℔ shells (loaded). Mitrailleurs have also been introduced for field artillery, and with them the range-finder, invented by Captain Nolan, R.A. The *siege* and *garrison* guns are 12 and 24-pounders, throwing 30 and 63-℔ shells, 8-inch bronze and steel guns, and 6 and 8-inch rifled mortars. For coast purposes guns from 6-inch to 11-inch calibre are used. The Russians have also introduced a 50-ton gun, or 1200-pounder, but the future will prove its efficiency. Krupp of Essen has been largely employed by the Russian Government for the supply of steel guns, but these are now furnished by Russian factories.

The field carriages are of wood and iron, that for the mountain gun of iron; but the former are now to be made of greater stability, and the carriages for siege and garrison artillery have also been improved. The projectiles used are the charokh and shrapnel for the mountain and field guns, chilled shot being used with the heavier ordnance.

The artillery of the active army consists of 48 brigades of field and 8 brigades of horse artillery, besides siege trains, parks, and mobile arsenals.

The horse artillery brigades (bodyguard excepted) consist of 4 batteries of 6 guns each. A brigade of field artillery consists of 5 field batteries (3 heavy and 2 light) and 1 mitrailleuse battery. There are four descriptions of batteries,—(*a.*) 9-pounder field batteries, (*b.*) 4-pounder field and horse batteries, (*c.*) 3-pounder mountain batteries, (*d.*) mitrailleuse batteries. Each battery has eight guns, drawn by six horses in time of war.

The two-wheel ammunition carts formerly in use are being gradually replaced by four-wheeled waggons. The mitrailleuse batteries carry 6290 rounds. In the 9-pounder battery there are 24, and in the 4-pounder 16 ammunition waggons.

The great increase and development of the Russian army, which began in 1873, was accompanied by a corresponding increase in the artillery, each brigade being raised from 4 batteries, its former strength, to 6, and a further increase of 2 batteries is probable. When the changes in progress are completed, the Russian field artillery will number 300 batteries, or 2400 guns.

Tactics.

The tactics of artillery, combined with the other arms, will be dealt with in another place (see WAR). The present article treats only of drills, and the simpler or uncombined tactics of artillery. Drill, though commonly included under the head of tactics, is rather the elementary training and education required for the higher development, and varies according to the nature of the artillery. The drills and instruction for *horse artillery* are as follows:—(1.) Equitation or riding drill. (2.) Foot drills, as for cavalry. (3.) Sword drill. (4.) Field gun drills. This includes the actual service of the gun, the loading, laying, and firing, &c., positions of gunners and detachments under various conditions, limbering up, unlimbering, exercise with drag ropes, &c.; also, such exercises as dismounting gun and carriage, mounting gun and carriage, replacing a damaged wheel, exchanging gun and limber wheels, shifting shafts from double to single draught, and *vice versâ*, moving disabled ordnance, &c. For details the reader is referred to the *Manual of Artillery Exercises.* (5.) Battery exercise (sometimes called by the horse artillery "gun drill"). In the horse artillery each subdivision consists of gun and waggon, with two non-commissioned officers, and six or eight gunners, besides drivers. Two gunners are carried on the limbers. The rest are mounted, and are called the detachment, which is placed in front, rear, or on a flank of the gun, according to circumstances. Ammunition waggons of horse artillery do not manœuvre usually, but merely conform to the movements of the guns at a safe distance. A battery of six guns in line occupies 95 yards, each gun being 19 yards from the next. When a battery comes into action, each detachment dismounts, the limber gunners get off the gun-limber to the rear, the trail is unkeyed, the limbers drive on, and the gun is placed in position, and the Nos. 1 lay them during the loading. They are then fired independently, unless the commanding officer gives orders to the contrary. "Limbering up" is the converse operation. The details of drill will be found in the *Manual of Field Artillery Exercises.*

Horse artillery.

Field artillery. *Field Artillery.*—The drill of a field battery is almost the same as that of a battery of horse artillery. The space occupied by a battery and the intervals are the same. There are, however, no mounted detachments, and the waggons usually accompany the guns in manœuvring, though on the battle-field they are supposed to be kept at a safe distance, and if possible under cover. The gunners are carried on the limbers and waggons when the battery moves faster than a walk. The provision of gun axletree seats now enables a sufficient number of men for the service of the gun to be kept with it under all circumstances. The drill for mountain batteries is not laid down anywhere, but is conducted on the same general principles as that of a field battery. Ease and celerity in coming into action is the great object in that as in all field artillery drills. At the word "halt, action, front," ("rear," "right," "left"), as the case may be, the carriage is taken off the carriage-mules, the wheels taken off the wheel-mule, and run up to the carriage and put on. The gun has by this time been lifted off by gunners by means of a handspike in the muzzle and one under the cascable, and is put on to the carriage. The movements of a mountain battery in "column of route," *i.e.*, single file, in "columns of subdivisions," the ammunition mules being alongside the gun and carriage mules, or in "columns of divisions," subdivisions being side by side, two and two, are merely adaptations of the manœuvres of field artillery.

Siege artillery. *Siege Artillery.*—The drills for the service of siege guns are numerous. Travelling carriages being used, the drill employed is a medium between field and garrison gun drills, and comprises unlimbering, limbering up, shifting from travelling to firing trunnion holes and, *vice versa*, the loading, laying, firing, &c., the mode of "taking post" under cover and at the gun.

Mortar drill would also come into this section, and embraces the manner in which the travelling mortar-beds are unlimbered and placed on the ground, and the converse operations, the detachment taking post at the mortar, the preparation for action, the mode of laying the mortar, loading, firing, &c. The laying of platforms also forms an important part of the duties of siege artillery. "Knotting" and the use of ropes and tackles is an essential branch of the drill. A siege artilleryman must be instructed in all the materials and appliances used in moving ordnance. Chains, levers, handspikes, fulcrums, skids, planks, rollers, crab capstans, lifting jacks, &c., all enter into his work. He must also be acquainted with the numberless operations by which siege guns are moved when dismounted, the mode of mounting and dismounting them, while the drills for gyns, sling waggons, sling carts, sheers, &c., are particularly his province.

Garrison Artillery.—The drills for garrison artillery embrace all those which come under the head of *siege*, but, further, comprise all the drills and exercises with heavy ordnance, such as drills with heavy guns on standing carriages, traversing platforms, and Moncrieff carriages, and with the enormous 10-inch, 11-inch, and 12-inch guns, fitted with special mechanical contrivances for loading, traversing; mounting and dismounting of heavy ordnance; and all kinds of work with sheers and derricks. The garrison artillery are also trained in the ordinary duties of infantry, viz., carbine, company, and battalion drill. All artillerymen are further instructed in the laying of ordnance, judging distance, and in the various laboratory operations which gunners are required to know, the handling of all kinds of projectiles, fuzes, &c.

The uncombined tactics of artillery. *Field Artillery Manœuvres.*—In manœuvring batteries, no fixed right or left is acknowledged, but only the front to which the guns point when in action, or the horse's face when limbered up. The paces used are the walk, trot, and gallop, and, according to Taubert, the "trot" is the most important. With us field batteries are strictly enjoined not to move beyond a trot, but there are occasions on which it is necessary for a battery to move at its quickest possible pace; and in Germany this is recognised and acted upon. Field artillery has increased in mobility by the recent change in *matériel* and the provision of axletree seats, so that there is no longer danger of a gun coming into action without a sufficient number of gunners to work it. Batteries should, therefore, be exercised to manœuvre with waggons at a safe distance, taking advantage of cover, but conforming to the movements of the guns.

Columns of artillery are composed of batteries, half batteries, divisions, subdivisions, and columns of route. Taubert divides artillery columns into (1) the column of march, (2), the rendezvous column, (3) the column of manœuvre. 1. With us the first is usually the "column of route" or single file, each waggon following its own gun in a long string. In the German army the guns come first, and then the waggons. This has the great advantage of not hampering the line of march, and is peculiarly adapted to the use of artillery with a large advanced guard. Columns of divisions may be used on a very broad road. 2. Rendezvous columns are open columns with the guns at full interval, so as to admit of guns, &c., reversing or taking ground to right or left. 3. The column of manœuvre may, when cover exists, be formed at close interval, but never so under fire. A close formation enables batteries to get near an enemy unseen, and the commander has the force well in hand, but this advantage should not weigh with the necessity for opening out for fire at the earliest moment. The best formation on the battle-field is that which admits of the easiest deployment for action. The position of guns is always governed by the nature of the ground, and "every possible advantage should be taken of this without paying too much attention either to intervals or dressing." The construction of gun-pits and epaulements for the waggons should be an important part of drill.

Positions for artillery must naturally be dependent on the character of the ground, and the objects to be executed by the guns. But where a choice exists, we must be guided by principles which secure us the vantage ground. A flat trajectory for our guns is highly important in diminishing the safe space for the enemy, and with this view a very elevated position is to be avoided. Such position is also bad if percussion fuzes are used, and the soil which the enemy occupies is soft. On the other hand, artillery do not now change their positions so frequently as in times past, and are more constantly required to fire over the heads of their own infantry; and a position sufficiently elevated to give a good command of the country and search out the enemy's position is therefore more required than formerly. Shell firing against troops under cover will also enter largely into the use of artillery in future, and for this command is of importance. A point of first importance in selecting a position is the absence of cover for the enemy within range of infantry rifle fire; and the position should be such that advance or retreat is easy. The brow of a hill, where the guns can be partly, and the limbers and waggons entirely covered by being withdrawn, is generally advantageous. The ground should be neither heavy nor stony. A good deal of controversy has taken place about the dispersion or concentration of guns for fire. If the object, *i.e.*, concentration of fire, can be attained by dispersion of batteries, it may be better under certain circumstances of ground to separate than to collect the artillery in large masses; on the other hand, dispersed batteries are much more out of control, and unable to receive the directing impress of one mind, and usually the employment of large masses of artillery will have a greater moral effect. The one object, concentration of fire, must be attained. Artillery positions.

The most powerful and effective position in which artillery can be placed is that in which, acting on a flank, it enfilades or takes in flank the enemy's troops. A remarkable illustration of this was given by Frederick the Great at Rossbach. At the battle of Talavera, July 28, 1809, the British guns changed position to the right, advancing from the left flank, and brought a destructive fire to bear on the French columns attacking from the centre of their line. At the battle of Bautzen, May 21, 1813, Napoleon's great manœuvre, in sending Ney to attack the right rear of the allied position, was frustrated by the fire of 20 Prussian guns taking Ney's columns in flank on the march. The battle of the Alma, September 20, 1854, gives an example of the effect produced by the enfilade fire of a few guns. Two guns of Turner's battery boldly advanced to a knoll which had been left unguarded almost in the centre of the Russian position, took the Russian columns in flank, and with such effect as almost to decide the fortunes of the day.

It has been explained that, in the early days of artillery tactics, guns had occasionally been massed, but usually with no clear aims as to their functions; nor was this state of things altered until far into the Napoleonic era. It was at the camp of Boulogne in 1805 that a truer system of tactics was first practised, and it was at the battle of Friedland, on the 14th June 1807, that the first striking example of the effect of artillery when employed in masses was given. The Russians had crossed the river Alle and taken up position in front of the town of Friedland. Ney had been ordered by Napoleon to drive back the Russian left and occupy Friedland, but had met with a severe check, when the French artillery general Senarmont collected the divisional artillery of the 1st corps, and, dividing it into two batteries of 15 guns each, with a reserve of 6 guns, placed a battery on each side of the road from Eylau, and by a converging and destructive fire of case broke the Russian columns, defeated all attempts on their part to resume the offensive, and finally drove the Russian left into the narrow defile and re-entering bend of the river.

At the battle of Wagram, 6th June 1809, Napoleon, pivoting on his left, advanced his right, turning the Austrian left, and attacked the centre with a mass of 100 guns. This imposing display of artillery power covered the French centre, and fixed the attention of the Austrian commander to the point, while the left was enabled to execute its turning movement. The French artillery, however, suffered excessively, the range being too short, and the want of mobility of the field batteries conspicuous.

The battle of Lützen or Gross-Görschen was fought between the allied Russians and Prussians and the French in May 1812. The former had 438 guns, the latter only 236. The allied artillery was not well handled, the fire being kept up in a dispersed and thriftless manner, the guns scattered between the infantry columns, and no powerful reserve being formed. Napoleon, reserving the artillery power he possessed, brought up a mass of 80 guns at the decisive moment, and with such effect that the allies gave ground and ultimately retreated.

The battle of Hanau, October 30, 1813, is a striking instance of an artillery fight. Napoleon was retreating from Erfurt after his defeat at Leipsic. Wrede barred his retreat, holding the issues of the forest of Hanau. Wrede had formed a battery of 60 guns, which for some time defeated all efforts of Napoleon to break out from the forest; and it was only Drouet's skilful concentration of fire, from three gradually reinforced masses of artillery upon Wrede's large battery, that enabled Napoleon ultimately to win his way out.

For other illustrations of the use of artillery on the battle-field, the reader is referred to Taubert's work *On the Use of Field Artillery*, translated by Col. H. H. Maxwell, R.A., and Hohenlohe-Ingelfingen's treatise *On the Employment of Field Artillery*, translated by Capt Clarke, R.A.

In the Italian campaign of 1859 a close country prevented much use being made of artillery, but at Solferino both Austrians and French massed considerable numbers of guns, and a brilliant example of the use of artillery was presented on the plain of Medole. M'Mahon having inclined to his left to support the attack on the Solferino heights, while Niel was fully engaged with a superior Austrian force on his right, a gap was created between these two corps. To fill this a mass of 42 guns, supported by cavalry, formed on the plain of Medole, and their fire frustrated all offensive attempts of the Austrians at this point. Rifled guns were employed by the French in this campaign, and without doubt contributed largely to their success.

In the struggle for supremacy of the two great German powers in 1866, both combatants were armed with the new weapons, but their proper applications seem to have been totally misapprehended. The Prussian batteries were kept too much in rear of the other troops while on the march, and came into action at ranges which only a very exaggerated view of the powers of rifled guns could justify. At Trautenau, Nachod, and Skalitz their artillery played an unimportant part; at Sadowa comparatively few of the vast number of their batteries came into effective action. The Austrian artillery had but little opportunity of displaying superiority of management or tactical training, though its heroism and self-sacrifice in covering the retreat on the eve of Sadowa is worthy of mention.

Till the campaign of 1870–71, the proper management and powerful effect of modern artillery was never thoroughly realised. The pungent criticism of certain anonymous writers on the 1866 campaign bore its fruits, and revolutionised the system of artillery tactics. From the storming of the Spichern heights up to the capture of Le Mans the same tactical features were prominent on the victorious side. A battle was preluded by the bold advance of all available guns. The attack commenced with a concentrated fire of artillery, the moral, if not actual, effect of which enabled an offensive movement of infantry to be made with success, or at least kept the enemy in check till the flanking movements, so conspicuous in this war, were carried out. At Wörth more than 100 guns were massed on the heights opposite Fröschwiller, and enabled a frontal attack to be made across the open valley of the Sauer. In the battles about Metz the massing of batteries was especially prominent. At Rezonville groups of 6 to 10 batteries acted in effective concert; at St Privat more than 200 guns cannonaded the French position for some hours. At Sedan the German guns were pushed forward regardless of escort, even in front of the advanced guards, and enclosed the ill-fated French army in what has been aptly described as a circle of fire.

In the Napoleonic wars guns were massed at the crisis of an engagement in order to strike a decisive blow, now they are assembled much earlier in order to render an attack possible. Modern artillery tactics may be summed up in a few words. The artillery of advanced guards is considerably increased, and the greater proportion of the corps and divisional guns march close to the head of the main columns. At the commencement of an engagement batteries are pushed to the front with great boldness, massed as much as possible, and concentrate their fire. Frequent change of position is deprecated, but guns must be kept within effective range, and their safety subordinated to the success of the other troops. The contemporaneous action of the three arms is more common than it used to be.

In future wars it is doubtful whether the independent action of artillery will not be somewhat restrained. Mechanical contrivances may make the accurate finding of ranges possible, and the employment of shrapnel shell, with an efficient time-fuze, render artillery fire more destructive than it has hitherto been. The action of mitrailleurs will probably be important when their efficacy and sphere of employment are thoroughly comprehended. No great improvement in the range and accuracy of fire of guns can be expected, as the practical limits of both have already been nearly reached. A few years may, however, witness the advent of a projectile power superior to gunpowder, and a shell more destructive than any at present in use. (See Guns and Gunnery.) (E. H. H. C.)

ARTOIS, an ancient province of the north of France, corresponding to the present department of Pas de Calais, with the exclusion of the arrondissments of Boulogne and Montreuil, which belonged to Picardy. It is a rich and well-watered champaign, producing abundance of grain and hops, and yielding excellent pasture for cattle. The capital of the province was Arras, and the other important places were Saint-Omer, Béthune, Aire, Hesdin, Bapaume, Lens, Lillers, Saint-Pol, and Saint-Venant. The name Artois (still more corrupted in "Arras") is derived from the Atrebates, who possessed the district in the time of Cæsar. From the 9th to the 12th century Artois belonged to the Counts of Flanders It was bestowed in 1180 on Philip Augustus of France by Philip of Alsace, as the dowry of his niece, Isabella of Hainault. In 1237 it was raised to the rank of a countship by Saint Louis in favour of his brother Robert. Philip, the son of Robert II., having died before his father, the transmission of the title was disturbed. The countship was claimed by Robert, Philip's son, and his descendants, better known as the counts of Edu, continued to style themselves counts of Artois; but it was actually inherited by Mahaud or Matilda, daughter of Robert II. By her marriage with Otho IV., Artois passed to the house of Burgundy, in whose possession it remained till the marriage of Mary, the daughter of Charles the Bold, to the Archduke Maximilian brought it to the house of Austria. By the peace of Nimeguen it was ceded to France in 1678. The title of count of Artois was borne by Charles X. of France before his accession to the throne.

ARU ISLANDS, a group of about thirty islands, nominally under the Dutch government of the Moluccas, which lie south of New Guinea, between lat. 5° 20′ and 6° 55′ S., long. 134° 10′ and 134° 45′ E. Tana-busar, the largest island, is 80 miles from north to south, and is crossed by three river-like creeks tunning east and west, called Watelai, Vorkai, and Maykor. No part exceeds 100 feet in elevation, but it is only on the coast that the ground is swampy. The principal formation is coralline limestone; the eastern coast is defended by coral reefs, and the neighbouring sea is shallow, and abounds in coral in full growth. The other islands of importance are Wamma, Pulo Bali, Oujia, and Wassia. A large part of the surface is covered with virgin forest, consisting of screw-pines, palm-trees, tree ferns, canariums, &c. Kangaroos, and a number of other marsupials, wild pigs, brush-turkeys, cassowaries, parroquets, cockatoos, birds of paradise, butterflies, ants, scorpions, sandflies, and mosquitoes are the predominant animals, the fauna being altogether Papuan. The aborigines belong to the Papuan race, but have received intermixture of foreign blood. They are a simple, emotional people, with dark-brown skins and frizzled hair. They wear little clothing, practise polygamy, purchase their wives, and are very lazy, and remarkably talkative. A few villages are nominally Christian, but elsewhere there seems to be no religion or even fetishism of any kind. In Wamma there is a town, Dobbo, to which Dutch, Malay, and Chinese traders resort once a year to traffic with the natives, obtaining trepang, pearl shell, birds of paradise, &c., and giving in exchange cloths, cutlery, muskets, gongs, tobacco, arrack, and elephants' teeth. The islands are thickly peopled, the inhabitants numbering about 60,000. The Italian naturalist Beccari spent some time among the islands in 1874; and Di Lenná, an Italian major, has executed a partial survey. (See Wallace's *Malay Archipelago*; *Ocean Highways*, 1873 and 1874; and G. Cora's *Cosmos*, 1873.)

ARUNDEL, a town in Sussex, on the river Arun, about 4 miles from its mouth, 10 miles E. of Chichester, 19 W. of Brighton, and 55 S.W. of London. It is built on the slope of a hill surmounted by the castle of the duke of Norfolk, which dates from the time of Alfred the Great. It confers on its possessor the title of Earl of Arundel. At the time of the Conquest the castle was rebuilt by Roger de Montgomerie, but it was taken from his son, who rebelled against the reigning monarch, Henry I. In 1397 it was the scene of a conspiracy organised by the earl of Arundel, archbishop of Canterbury, and duke of Gloucester, to dethrone Richard II. and murder the lords of his council, a plot which was discovered before it could be carried into execution. During the parliamentary wars of the 17th century the stronghold was frequently assaulted by the contending parties, and consequently greatly damaged; but it was restored by Charles the 11th duke of Norfolk, who made it what it now is, one of the most splendid baronial mansions in England. The town which, according to the whimsical etymology of the corporation seal, takes its name from *hirondelle* (a swallow), is divided into two parts by the river Arun, which is here navigable for vessels of 300 tons, and a canal connects it with the Thames and Portsmouth. The town-hall is a castellated building, which cost £9000, and was presented to the corporation by the duke of Norfolk. The church of St Nicholas is a very ancient structure (founded about 1375), with a low tower rising from the centre. In the north aisle of the chancel there are several ancient monuments of the earls of Arundel, and the high altar is held to be the only perfect original example in England. The church is otherwise remarkable for its reredos and iron work. Some remains of a *Maison Dieu*, or hospital, erected in the time of Richard II. still exist. Arundel was a borough by prescription, and returned two members to parliament from the time of Edward I., but it lost one by the Reform Act of 1832, and the other by that of 1868. (See Tierny's *Hist. of Castle and Town of Arundel*, 2 vols., 1834.)

Arms of Arundel.

ARUNDEL, Thomas, Archbishop of Canterbury, born in 1353, was the second son of Robert, earl of Arundel and Warren. At 22 years of age he was raised to the bishopric of Ely, to the church and palace of which he was a great benefactor. In 1386, after the deposition of the earl of Suffolk, he was appointed lord chancellor of England; he was deprived of this office in 1389, but again reinstated. In 1388 he was translated to the see of York, and in 1396 was advanced to the primacy of Canterbury, when he resigned the chancellorship. This was the first instance of the translation of an archbishop of York to the see of Canterbury. Scarcely was he fixed in this see when he had a contest with the University of Oxford about the right of visitation. The affair was referred to the king (Richard II.), who determined it in favour of the archbishop. At his visitation in London he revived an old constitution, by which the inhabitants of the respective parishes were obliged to pay to their rector one halfpenny in the pound out of the rent of their houses. While bishop of Ely, Arundel had taken a leading part in forcing the king to consent to the commission of regency; Richard never forgave this, and in 1397 the parliament, with the king's leave, impeached the archbishop, with his brother Richard earl of Arundel, and the duke of Gloucester, on a charge of high treason. He was sentenced to be banished, and to depart the kingdom within forty days on pain of death. He retired, first to France, and then to the court of Rome, where Pope Boniface IX. gave him a kind reception, and nominated him to the Scottish archbishopric of St Andrews. He was actively engaged in the plot to depose Richard, and place the duke of Lancaster on the throne; and on Henry's accession, he was restored to the see of Canterbury. Two years after, the Commons moved that the revenues of the church might be applied to the public service, but Arundel opposed the measure with such vigour that it was thrown out. In the year 1408 his zeal for the suppression of heresy was directed against the followers of Wycliffe. Sir John Oldcastle, Lord Cobham, was arrested by his orders, and sentenced to the flames, but contrived to escape from prison. The archbishop also procured a synodical constitution, which prohibited the translation of the Scriptures into the vulgar tongue. He died at Canterbury on the 20th February 1413 of inflammation of the throat, with which he was seized, as was affirmed by the Lollards, while pronouncing sentence upon Lord Cobham.

ARUNDELIAN or OXFORD MARBLES, part of a collection of ancient sculptures and antiquities, including the famous Parian Chronicle, formed by Thomas earl of Arundel, and presented by his grandson, the Hon. Henry Howard (afterwards duke of Norfolk), to the University of Oxford in the year 1667. They were purchased for the first proprietor in 1624 by Mr (afterwards Sir William) Petty, who, along with John Evelyn, had been employed by the earl of Arundel to collect marbles, books, statues, and other curiosities in Italy, Greece, and Asia Minor. On their arrival in London in the year 1627 they were placed in the gardens of Arundel House, the site of which is now occupied by Arundel, Norfolk, Surrey, and Howard Streets in the Strand. Thomas Howard, earl of Arundel and Surrey, the founder of the collection, was born in 1586 (or, according to others, 1592). He had at first only the honorary title Lord Maltravers, but in 1603 he was restored to most of the honours previously in the possession of his family. For several years he resided or travelled in Italy, and there acquired a strong taste for works of art, specimens of which he began to collect. In 1621 he was made earl marshal of England, and afterwards discharged the offices of ambassador, general, and lord high steward. He went abroad in 1641, and died at Padua in 1646. His large collection contained not only sculptured marbles, but also coins, busts, statues, and gems. In the turbulent reign of Charles I., and during the Protectorate, Arundel House was often deserted by its owners; and, in their absence, some of the marbles were defaced and broken, and others either stolen or used for the ordinary purposes of architecture. After the death of the earl his collection was divided among his family. The inscribed marbles, which fell to the elder son, ultimately found their way to Oxford; the busts and some statues were sold and dispersed; and the gems descended to the Marlborough family, in whose possession they now are. Some of the statues, which had been purchased at the sale of Arundel House by Sir William Fermor, were presented to the University of Oxford in 1755. Of the large collection now known as the Arundel or Oxford marbles the most remarkable is the Parian Chronicle, or Marmor Chronicon. This when found consisted of a large oblong slab of Parian marble, on which was engraved in capital letters a chronological compendium of the principal events of Greece during a series of 1318 years, beginning with the reign of Cecrops, 1582 B.C., and ending with the archonship of Diognetus, 264 B.C. The marble originally measured 3 feet 7 inches and 2 feet 11 inches on the two sides respectively, its breadth being 2 feet 7 inches; but the chronicle of the last 90 years is lost, so that the part now remaining ends with the archonship of Diotimus, 354 years before the birth of Christ; and in this fragment the inscription is at present so much corroded and effaced that the sense must in some measure be supplied by conjecture. Immediately on the arrival of these marbles in England the greatest curiosity was excited among literary men. Selden, with the assistance of some other scholars, cleaned and examined first the marble containing the Smyrnean and Magnesian league, and then the Marmor Chronicon. The following year Selden published a small volume in quarto, including about 39 inscriptions copied from the marbles. His researches were continued and completed by Prideaux (1676), Maittaire (1732), and Chandler (1763). The Arundelian marbles, though generally regarded as genuine relics of antiquity, have been discovered in some instances to differ somewhat from the most authentic historical accounts. Their authenticity was called in question in a dissertation by the Rev. J. Robertson, published in 1788, entitled *The Parian Chronicle*. This essay has been answered by several writers, particularly by the eminent scholar, Professor Porson, and the authenticity of the marbles may be regarded as fairly established. See Boeckh, *Corpus Inscriptionum Græcarum*, 1843.

ARVAL BROTHERS (*Fratres Arvales*), in *Roman Antiquities*, a college or priesthood (*sacerdotes arvorum*), consisting of twelve members, elected for life from the highest ranks in Rome, and always apparently, during the empire, including the emperor. Their chief duty was to offer annually public sacrifice for the fertility of the fields (*ut fruges ferant arva*). The origin of the brotherhood was traced to Acca Larentia, the foster-mother of Romulus, who, with her twelve sons, had instituted sacrifices of this kind, and probably this legend arose from the connection of Acca Larentia, as *mater Larum*, with the Lares who had a part in the religious ceremonies of the arvales. But apart from this, there is proof of the high antiquity of the college in the verbal forms of the song with which, down to late times, a part of the ceremonies was accompanied, and which is still preserved (Becker, *Handbuch der Röm. Alterthümer*, iv. p. 407). It is clear also that, while the members were themselves always persons of distinction, the duties of their office were held in high respect. And yet it is singular that no mention of them occurs in Cicero or Livy, and that altogether literary allusions to them are very scarce. On the other hand, we possess a long series of what may be called the minutes of their proceedings, drawn up by themselves, and inscribed on stone. At the time of Marini (*Gli Atti e Monumenti de' Fratelli Arvali*, Roma, 1795) 67 of these sets of records were known, beginning at 14 A.D. and extending to the time of Gordian. Since then several others have been discovered. The college consisted of a master (*magister*), a vice-master (*promagister*), a *flamen*, and a *prætor*, with eight ordinary members, attended by various servants, and in particular by four boys, sons of senators, having both parents alive. These officers were elected annually in May, but did not enter on their duties till the 17th December. Each wore a wreath of grain, a white fillet, and the prætexta. The great annual festival which they had to conduct was held in honour of the Dea Dia, who appears to have resembled the goddess Ops, the wife of Saturn. It occupied three days, and fell either on the 17th, 19th, 20th, or the 27th, 29th, 30th of May. The ceremony of the first day of the May festival took place in Rome itself, in the house of the magister or his deputy, or *in Palatio Divorum*, where after sunrise the peculiar ceremony was gone through of "touching" (*tangere fruges*) samples of the old and the young grain. On the second and principal day of the festival the ceremonies were conducted *in luco Deæ Diæ*, that is, in a grove just beyond the fifth milestone from

Rome on the Via Portuensis. The first act was to sacrifice two young pigs (*porciliæ piaculares*) to purify the grove, which, it was held, was liable to be defiled in a religious sense by the felling of trees, and by the presence in it of any iron tool or instrument, such as was required by the lapidary who engraved on stone the records of the proceedings. Then, after the sacrifice of a white cow, the magister drew up a minute of what had been done, and all retired to their tents. At midday they again met, settled and confirmed the minutes, and the public being now excluded, went into the depth of the grove to sacrifice a fat sheep. Returning to the temple, the *thesauri*, which seem to have been money collected from the people present, were placed on the altar, and the arvales arranged themselves in a line, with an attendant at each end. The attendant at one end received from the public the samples of grain and fruits which they had brought to be "touched," or blessed, and handed them to the brother next him, who passed them on till they reached the attendant at the other end, who restored them to the owners. The arvales now entered the temple, and with closed doors proceeded to dance and sing the song of the brotherhood, which is known to have been sung by them in its ancient form down to the 3d century A.D. This was followed by the election of officers for the next year, a banquet, and races. On the third day the sacrifice took place in Rome, and was of the same nature as that offered on the first day. Among the many minor occasions on which the arvales had to offer sacrifice were the birthday of an emperor, the beginning of a consulate, an escape from danger, the starting for or return from a journey, or other event of importance to the imperial family, but especially on the 3d of January, on which day a particular form of prayer for the ruling emperor was recited, and sacrifice offered to a series of deities, male animals to male deities, and female to female. In the British Museum is a bust of Marcus Aurelius in the dress of a Frater Arvalis. (Henzen in the *Hermes*, ii. p. 37; De Rossi, *Annali d. Inst. Arch. Rom.*, 1858, p. 58.)

ARVE, a river which rises in the Col de Balme, one of the Savoyan Alps, and passing through the valley of Chamouni, falls into the Rhone near Geneva, after a course of about 50 miles. (See *Journ. R. Geog. Soc.*, vol. xxvii.)

ARYAN, a technical term, applied to one of the great families of language, which extends from India to Europe, and which, for that reason, is called also *Indo-European*. Friedrich Schlegel, who first recognised the family relationship of these languages (*Die Sprache und Weisheit der Indier*, 1808), assigned to them the name of *Indo-Germanic*, a name still used by preference by many scholars in Germany (Pott, Benfey, &c.) Bopp (*Vergleichende Grammatik*, vol. i. p. xxiv.) decided in favour of *Indo-European* as a more appropriate name for that large family of speech. Other scholars have used the names *Japhetic*, *Sanskritic* (W. von Humboldt), and *Mediterranean* (Ewald).

The objection to *Indo-Germanic* as the technical name of the whole family is that it is too long, and yet not sufficiently extensive. If the family is to be distinguished by the names of its two extreme members, the name ought to be *Indo-Celtic*, rather than Indo-Germanic; if by its most important members, then, as remarked by Bopp, the name should be *Indo-Classic*. *Indo-European* is an equally cumbersome name, and less correct even than Indo-Germanic, considering that there are many languages spoken both in India and Europe which do not belong to that family. *Sanskritic* would be a misleading name, as countenancing the idea that all the members of this family are derived from Sanskrit. *Japhetic* seems to revive the Jewish conception of the three ancestors of the human race, *Shem*, *Ham* and *Japhet* and would, from the strictly Hebrew point of view, comprehend many tribes in the north of Asia and Europe who speak Turanian languages. Ewald, who suggested the name of *Mediterranean*, distinguishes, besides the Mediterranean, three other families of speech, the *Northern*, commonly called North Turanian or Altaic, the *Semitic*, and the *Copto-African*. He explains the name of Mediterranean by saying, that "the races speaking these languages inhabited the large central circle, surrounded by Semitic, South-Indian, Chinese, Turko-Tataric, and Bask languages" (*Lehrbuch der Hebräischen Sprache*, p. 17, note). The reason why this name has not been accepted, seems to be that locality has little to do with the essential character of languages, and that the central position once occupied by the people who spoke these tongues belongs to them no longer.

Aryan, as a name for a whole family of languages, has the advantage of being short, and, being a word of foreign origin, of lending itself more easily to any technical definition that may be assigned to it. It has been accepted by many writers in England, France, and India. In Germany, too, it is used in this wide sense by Lassen and others, while some scholars have used the term in the more restricted sense of *Indo-Iranian*,—*i.e.*, as comprehending the languages of India and Persia, which constitute the south-eastern as distinct from the north-western (Greek, Latin, Celtic, Teutonic, Slavonic) branch of the family.

Origin of the Word.—*Aryan*, as a technical term, has been borrowed from the Sanskrit *arya* or *ârya*, the Zend *airya*. In the later Sanskrit *ârya* means, of a good family. It is used as a complimentary address. Originally, however, it was used as a national name, and even as late as the time of the Laws of Manu, India is still called *Ârya-âvarta*, *i.e.*, the abode of the Aryas. In the Veda, *Ârya* is the name by which the believers in the gods of the Veda call themselves, in opposition to their enemies, who are called *Dāsas* or *Dasyus*. The distinction appears in passages such as the following:—

I. 51, 8. "Distinguish, Indra, the *Âryas* and those who are *Dasyus*" (vî *g*ānihi ā́ryān yé *k*a dásyava*h*).

X. 86, 19. "I, Indra, distinguishing the *Dāsa* and the *Ârya*" (vi*k*invân dā́sam ā́ryam).

We frequently read of the gods protecting the *Ârya* and destroying his enemies.

III. 34, 9. "Indra, having killed the *Dasyus*, protected the *Âryan* colour" (hatvî dásyūn prá ā́ryam vár*n*am āvat). This looks like an ethnological distinction of colour between *Aryas* and *Dasyus*.

X. 49, 3. "I (Indra) who do not give over the *Âryan* name to the *Dasyu*" (ná yá*h* raré ā́ryam nā́ma dasyáve).

In X. 11, 4, we read of Aryan clans, ā́ryā*h* visa*h*

I. 103, 3. "Indra, increase the *Âryan* power" (ā́ryam sáha*h* vardhaya).

VIII. 103, 1. "Agni, the increaser of the *Ârya*" (ā́ryasya várdhanam).

VII. 18, 7. "Indra, the companion of the *Ârya*" (sadhamā́*h* ā́ryasya).

I. 130, 8. "Indra protected in battles the *Âryan* sacrificer" (I′ndra*h* samátsu yá*g*amānam ā́ryam prá āvat).

The gods, it is said, bring light for the Arya.

I. 59, 2. "Agni is made a light for the *Ârya*" (tám tvā devā́sa*h* a*g*anayanta devám vais*v*ānara *g*yóti*h* ít ā́ryāya); or, "Agni creates broad light for the *Ârya*, driving the *Dasyus* from the house" (VII. 5, 6).

II. 11, 18. "He (Indra) uncovered the light for the *Ârya*, the *Dasyu* was left on the left hand" (ápa av*r*i*n*o*h* *g*yóti*h* ā́ryāya ní savyatá*h* sādi dásyu*h* indra).

IV. 26, 2. "I gave the earth to the *Ârya*, and rain to the liberal mortal" (Ahám bhū́mim adadām ā́ryāya ahám v*r*ish*t*ím dāsúshe mártyāya).

117, 21. "The two Asvins have made the light wide for the *Ārya*" (urú gyótih kakrathuh ãryāya).

That light itself, the light of the day or the daily light and life, are called the *Āryan* light, X. 43, 4, and some of the gods too are addressed by the name of *Ārya*. In V. 34, 6, we read of Indra, "that he, the *Ārya*, leads the *Dāsa*, according to his will" (yathāvasám nayati dãsam ãryah). In X. 138, 3, too, Indra seems to be called by that name.

Most frequently, no doubt, the *Ārya* is conceived as the worshipper of the gods. He was called so in I. 130, 8; again in I. 156, 5, *Ārya* and *Yagamāna*, sacrificer, are mentioned together.

In IX. 63, 5, the *Ārya* is opposed to the *árāvān*, the enemy, the man who offers no sacrifices; and I. 51, 8, the same distinction is drawn between the *barhishmat*, the sacrificer or *Ārya*, and the *avratá*, the lawless, the *Dasyu*.

But the enemies of the poets and their friends are not only among the *Dasyus*, but also among the *Āryas*, and in their tribal feuds one Ārya speaks of the other as *adeva*, godless, in the original sense of the word. Thus we read:—

X. 102, 3. "Turn away the weapon of the *Dāsa* or the *Ārya*" (dãsasya vā maghavan ãryasya vā sanutáh yavaya vadhám).

X. 83, 1. "Let us withstand the *Dāsa*, the *Ārya*, with thee as helper" (sahyãma dãsam ãryam tvấyā yugã).

VI. 33, 3. "Thou, O hero, struckest these two enemies, the *Dāsa* fiends and the *Ārya*" (tvám tãn indra ubháyān amítrān dãsā vritrãni ãryā ka sūra vádhih).

VI. 60, 6. "They (Indra and Agni) kill the *Ārya* fiends, they kill the *Dāsa* fiends, they strike off all haters (fem.)" (hatáh vritrãni ãryā hatáh dãsāni sátpatī hatáh visvāh ápa dvíshah).

Similar passages, mentioning *Ārya* and *Dāsa* enemies, occur, VI. 22, 10; VII. 83, 1, X. 69, 6, &c. In VIII. 24, 27, the *Ārya* enemy is contrasted with the *riksha*, literally, the bear.

The *Arya* enemy is called godless in X. 38, 3, "Whatever *Dāsa* or godless *Arya* means to fight us". (yáh nah dãsah ãryah vā purustuta ádevah indra yudháya kiketati).

Lastly, *Ārya* means in some passages what befits or belongs to an *Arya*, what is proper and right.

X. 65, 11. "The gods spread all over the earth the *Āryan* laws" (sudānavah, ãryā vratã vi srigántah ádhi kshámi).

In IX. 63, 14, the sacred receptacles of the Soma are called *ārya* (eté dhãmāni ãryā sukrãh ritásya dhãrayā vãgam gómantam aksharan).

It is clear from these passages that *Arya* is one of the oldest names by which people belonging to this great family of speech called themselves in distinct opposition to their enemies. It is admitted also that the Veda, in which this name occurs, surpasses in antiquity every other literary document belonging to the same race, and it would be difficult, therefore, to find another name better adapted to serve as a technical term for the whole Aryan family of languages.

As *Ārya* had become a proper name as early as the poems of the Veda, its original and etymological meaning would be of little consequence, had it not been used as an additional argument both in favour of and against the technical use of Ārya. Professor Bopp derived ãrya from the root ar, to go, or even from ark, to venerate. The former etymology would give no adequate sense, the latter is impossible. Lassen explains ãrya as *adeundus*, like ãkārya, teacher. But in explaining ãrya, it must be remembered that it cannot be separated from árya with a short a, and that in consequence no etymology of ãrya can be entertained which does not at the same time account for árya. This word is used in the Yagurveda in exactly the same sense as ãrya in the Rig-veda. Thus we read, Vāgasaneyi-Sanhitā, 20, 17, "Whatever sin we have committed against an Arya, or against a *S*ūdra" (yák khūdré yád árye yád énas kakrimã vayám).

Here Arya is used in opposition to *S*ūdra, as Arya was used in the Rig-veda in opposition to Dāsa. In the Rig-veda, too, we find at least some traces of arya, used in the sense of ārya, and in opposition to dāsa, viz., in the compound aryá-patnī, having an Arya as husband, as opposed to dāsá-patnī, having a Dāsa as husband.

There can be no doubt, therefore, that ãrya, the word which, as soon as the system of the four castes became more firmly established, took the technical meaning of "belonging to the three upper castes," viz., the Brāhmanas, Kshatriyas, and Vaisyas, came from ărya, and that in *ărya* must be discovered the original etymological meaning of the word.

Here it is of great importance to observe, that ărya is not only used as a comprehensive title of the three upper castes, but also as the special name of one of them, viz., the third caste, the householders or cultivators of the soil.

In Vāgg-Samhitā, XXVI. 2, it can mean nothing but Vaisya, a man of the third class, for it is used together with Brahman, Rāganya, and *S*ūdra. It is therefore not the commentator only, as Dr Roth says, who here gives the meaning of Vaisya to the word árya, but, from the context itself, it can have no other meaning in that passage. This meaning is still clearer in a passage from the Lātyāyana Sūtras, IV. 3, 6. Here it is said that some sacrificial act should be performed, primarily by an Ārya, but if no Ārya is forthcoming, then by any Ārya, *i.e.*, either by a Brāhmana or Kshatriya (Aryābhāve yah kas kāryo varnah. Comment, yadi vaisyo na labhyate yah kas kāryo varnah syāt, brāhmano vā kshatriyo vā).

Pānini (III. 1, 103) distinctly ascribes to árya the meaning of Vaisya and master; in IV. 1, 49, the 7th Vārttika distinguishes between Arya and Kshatriya; and what is still more important, both the author of a Vārttika to Pān., III. 1,103, and the author of the Phit-sūtras, state that when árya means Vaisya, it has the accent on the first syllable, like ãrya.

Having thus traced the connection of ãrya and árya, both in form and meaning, we have now to consider how *árya* came to mean Vaisya. Vaisya, is formed from vis, house, settlement, like ãrya and árya, from ar. We have also vesyām in the Veda, meaning, as it seems, family or clan. Vaisya, meant a householder, and vis also, plural visah, is frequently used in the Veda as a name for people. Other old names for people in the Veda are kshiti, a dwelling and a dweller, from kshi, to dwell; Greek, κτι in ἀμφικτίονες; or krishti ploughing or ploughers.

If, therefore, there was a Sanskrit word *ar*, meaning earth, then árya, in the sense of landholder, or countryman, would have been formed regularly like Kshámya, χθόνιος, from ksham, χθών, earth; like gávya, from go, cow, nárya, from nár, man. Now ar, in the sense of earth, does not occur in Sanskrit; but that such a word existed is proved by its derivatives. The Greek ἔρα in ἔραζε would correspond to a Sanskrit irā, which irā again stands to ir, like kshudhā, hunger, to kshudh. Finally, ir must be traced back to a radical ar, the change of a to i being analogous to that of Sk. pitar, father, as compared with πατήρ, pater, Goth. fadar.

The question now arises, whether irā or ir ever occurs in Sanskrit as a name of earth. The native dictionaries, such as the Amarakosha, assign that meaning to irā, and to ilā, and the latter form occurs in the famous name of Ilāvrita (explained as ilā prithivī vritā yena), the district of *Ilā*, the centre of gambudvīpa or India, gambudvīpa itself being the centre of the seven great continents of the world (Vishnu-Purāna, B. II. cap. 2).

In the Rig-veda irā occurs but once, and there, V. 83, 4, it has the meaning of food springing from the earth. "Food is produced for every being, when Parganya quickens the earth with seed" (írā vísvasmai bhúvanāya gāyate yát pargányah prithivîm rétasā ávati).

Here irā cannot mean simply "a liquid, a draught, feast, particularly a draught of milk;" for the simile shows that the rain is taken as seed, and that from it the food (irā) is supposed to spring (gāyate).

In another passage in the Atharva-veda, IV. 11, 10, irā may mean earth, but the sense is doubtful. If it be asked how irā, originally meaning earth, could take the meaning of food, we must remember the tendency of ancient language to mix up cause and effect, the producer and the produced. Irā, meaning originally earth, would be used in many circumstances as the food and sustenance supplied by the earth, just as gauh, cow, in the Veda is used, not only for milk, but even for leather.

The adjective irāvat means possessed of nourishment, nourishing. Anira means without food, and anirā amîvā seems to be a name for famine. In one place, Rig-veda, IX. 97, 17, ilāvat stands for írāvat; vrishtím nah arsha divyām gigatnúm ílāvatīm, "Give us the heavenly, streaming, fruitful rain."

Considering the antiquity of the name arya, we may refer its origin to a period in the history of the Aryan language, when the primitive substantive ar was still used instead of the later *arā, irā, ἔρα. As from χαμᾶζε we should be justified in postulating the former existence not only of χαμᾶ, earth, but even of a more primitive substantive χαμ, which is actually preserved in χθών, so from ἔραζε, we conclude the former existence not only of ἔρα, but also of a substantive ἐρ, Sk. ar.

Whether ărya means born of the earth, or holding, cultivating, possessing the earth, in either case such a name finds ample analogies in the names by which the early dwellers on the earth spoke of themselves. It is not in modern languages only that people call those of their own country, *Landsmann*, countryman, but in Greek, too, γηίτης is used in that sense, while γείτ-ων, equally derived from γῆ, means neighbour. The Latin vicinus, neighbour, is derived from vicus, the Greek, οἶκος, the Sanskrit, vesa; all connected with the Sanskrit vis, dwelling or dweller, the synonym of ărya in Sanskrit. In Gothic, gaujan, a countryman, is derived from gauja, land, probably connected with χαμ in χαμ-ᾶ-ζε. Connected with this same χαμ (χθών, χθαμαλός) is the Gothic guma(n), man; Lithuanian, žmón-es, plur., men; and the Latin, hemōnes (nehemo = nemo), and homines, men, not derived from humus, but from an older nominal base, ham, hem, or hom.

Mythology also supplies several instances showing that man was conceived as born of the earth, the son and then the lord of the earth, made of dust, and meant to "till the ground from whence he was taken." Erechtheus or Erichthonios (both chtheus and chthonios point to χαμ), the national hero of the Athenians, worshipped in the oldest shrine on the Acropolis, was represented as γηγενής or αὐτόχθων (Her., VIII. 55), while Homer (*Il.*, II. 548) says of him that the Earth bore him (τέκε δὲ ζείδωρος ἄρουρα). Hellen is the son of Pyrrha, and Pyrrha, the red, was the oldest name of Thessaly. The Germans derive their race from Mannus, who was the son of Tuisco, the heavenly, who was the son of the Earth.

The root ar, which as a substantive supplied the oldest names for earth, took in its verbal application the meaning of ploughing, at least among the members of the north-western branch, Gr., ἄρο-τρον, ἀρο-τήρ, ἀρό-ω; Lat., ar-ā-re, ar-ā-trum, ar-ā-tor; Goth., ar-jan, to ear; Lith., ar-ti, to plough; Old Slav., oralo, plough; Irish, airim, I plough, arathar, plough. In the south-eastern branch it took the technical meaning of ploughing the sea, Sanskrit, ari-tram, meaning rudder, never plough (*cf.* κύματα τέμνειν and ἄρουραν τέμνειν). Yet the meaning of moving, stirring up, belonged to the root ar from the beginning, and though we ought not to derive *ar, *arā, irā, ἔρα, from a root ar, to plough, as little as homo from humus, we may well understand how ar, as the broken, reclaimed, arable land could be used, even before the Aryan separation, as one of the names of earth.

The common etymology which would assign to ărya the meaning of "belonging to the faithful" (Roth) is untenable, because arya, with the short a and accent on the last syllable, does not mean faithful or devoted, and it is extremely doubtful whether arí, from which aryá is said to be derived, occurs anywhere in the Veda with the meaning of desirous, devoted, or faithful. But even if it did, it would be impossible to leave out of consideration the name árya, meaning simply landholder, Vaisya, without any admixture of the meaning of faithful or devoted. The national name, ărya, comes directly from this árya, landholder, and árya, landholder, comes from ar, land, not from ari, which means enemy. To distinguish aryá, as a term of honour, in the sense of lord or master, from árya, the mere appellative, a change of accent was admitted, which is recognised by the earliest grammarians who mention aryá, lord, as distinguished from árya, landlord, while no native authority ever assigns to arya, still less to ari, the meaning of faithful.

Arya and Ārya, as national names, can be traced from India to Persia. In the Avesta, *airya* means venerable, and is at the same time the name of the people. The first country created by Ormuzd or Ahuramazda is called in the Avesta, Airyanem vaēgō, *Arianum semen.* The whole extent of country occupied by the worshippers of Ormuzd is also called Airyā. As opposed to the Aryan clans (airyāo dainhāvo), we hear in the Avesta of the un-Aryan clans (anairyāo dainhāvō), and the same name is contained in the Ἀναριάκαι of Strabo, a people and town on the frontiers of Hyrcania. Greek geographers use the name of Ariana in a wider sense than the Avesta. All the country between the Indian Ocean in the south and the Indus on the east, the Hindu-Kush and Paropamisus in the north, the Caspian gates, Karamania, and the mouth of the Persian Gulf in the west, is included by Strabo under the name of Ariana; Bactria is called by him the ornament of the whole of Ariana. As the Zoroastrian religion spread westward, Persia, Elymais, and Media, all claimed the Aryan title. Hellanicus, who wrote before Herodotus, gives Aria as a name of Persia. Herodotus attests that the Medians were called Arii; and even for the northernmost part of Media, Atropatene, the name of Ariania has been preserved by Stephanus Byzantinus. Even Elymais has been supposed to be derived from Ailama, a modification of Airyama. That airya was considered a name of honour we see from the cuneiform inscriptions. There Darius calls himself Ariya and Ariyakitra, an Aryan, and of Aryan descent. The same element enters into many historical Persian names, Ariaramnes, Ariobarzanes, &c. When after centuries of foreign invasion and occupation Persia rose again under the sceptre of the Sassanians to the rank of a national kingdom, the kings, the worshippers of Masdanes, called themselves again in their inscriptions, Kings of the Aryan and un-Aryan races, Irān va Anirān, Ἀριάνων καὶ Αναριάνων. Hence the modern name of Persia, Irán.

In the name of Armenia the same element of arya has been supposed to exist. The old name of the country is Armina, and its etymology is doubtful. In the language of Armenia, however, ari exists, used in the widest sense for Aryan or Iranian, and also with the meaning of brave.

More westward still traces of the name have been discovered in Aghovan, the name of the Albanians on the border of the Caspian Sea, the gh being the representation of an original r or l. In the Caucasus itself the only class speaking an Iranian language, the Os of Ossethi, call themselves Iron.

Along the Caspian and in the country washed by the Oxus and Yaxartes, Aryan and non-Aryan tribes were mingled together. Their wars find their poetical record in the Persian epic, the Shahnameh, describing the feuds and friendships between Iran and Turan. Many Scythian names, preserved by Greek writers, have an Aryan character. Beyond the Oxus, in Transoxiana, too, people are mentioned under the name of Ariacæ and Antariani. Here, however, all certain traces of the word, as a geographical term, vanish. We have indeed Aria as an old name of Thrace, and on the Vistula we meet a German tribe called Arii; but nothing is known of the origin of these names, and no conclusions should be built on them.

It should be mentioned that some scholars (Curtius) connect the Greek ἄριστος with Sanskrit arya, though deriving it from a different root; while others (Pictet) recognise arya in the Irish er, good, brave, hero. (F. M. M.)

AS, an ancient weight, consisting of 12 ounces, identical with *libra*, the Roman pound. The word is common in the old Italic dialects, and may perhaps be connected with the Greek *αἶς*, which, in the Doric dialect, is used for εἷς, *one*, *i.e.*, an entire thing; according to others it is derived from *æs*, because made of the mixed metal known under that name.

It was also the name of a Roman coin, which was of different weight and value at different periods. The first introduction of coined money is ascribed to Servius Tullius, who probably borrowed from the neighbouring Etruscans the general form and scale of value. The old *as* was composed of the mixed metal *æs*, an alloy of copper and tin, and was called *as libralis*, or *librarius*, because actually weighing a pound or 12 ounces. The *asses* were cast in a mould, and their original shape seems to have been an irregular oblong, which was stamped with the figure of a sheep, ox, or sow. After the round shape was introduced, the one side was always inscribed with the figure of a ship's prow, and the other with the double head of Janus. The subdivisions of the *as* had also the ship's prow on one side, and on the other the head of some deity. The first Punic war having exhausted the treasury, the *as* was reduced to two ounces. In the second Punic war, it was again reduced to half its weight, viz., to one ounce. And lastly, by the Papirian law it was further reduced to the diminutive weight of half an ounce. It appears to have been still more reduced under Octavianus, Lepidus, and Antony, when its value was $\frac{1}{3}$ of an ounce. It probably continued at this value till the time of the Emperor Severus, when it was again lowered to about $\frac{6}{24}$ of an ounce. During the commonwealth and empire *æs grave* was used to denote the old *as* in contradistinction to the existing depreciated coin; while *æs rude* was applied to the original oblong coinage of primitive times.

As also denoted any integer or whole; whence the English word *ace*. Thus *as* signified the whole inheritance; whence *hæres ex asse*, the heir to the whole estate.

ASAFŒTIDA, a gum-resin obtained principally from *Narthex asafœtida*, and probably also from one or two other closely allied species of umbelliferous plants. It is produced in the southern provinces of Persia, in Bokhara, and in Beloochistan, and the plant grows as far south as the Chenab Valley in the Panjab. *Narthex asafœtida* grows to a height of from 5 to 6 feet, and when the plant has attained the age of 4 years, it is ready for yielding asafœtida. The stems are cut down close to the root, and the juice flows out, at first of a milky appearance, but quickly setting into a solid resinous mass. Fresh incisions are made as long as the sap continues to flow, a period which varies according to the size and strength of the plant. A freshly-exposed surface of asafœtida has a translucent, pearly-white appearance, but it soon darkens in the air, and assumes a yellowish-brown colour. In taste it is acrid and bitter; but what peculiarly characterises it is the strong alliaceous odour it emits, from which it has obtained the name asafœtida, as well as its German name *Teufelsdreck* (devil's dung). According to the analysis of Pelletier, asafœtida contains of resin, 65·0; soluble gum, 19·4, bassorin, 11·2; volatile oil, 3·6; and malate of calcium, 0·3 per hundred parts. The oil, to which its peculiar odour is entirely due, can be distilled off with water, and contains from 20 to 25 per cent. of sulphur. Asafœtida is found in commerce in "lump" or in "tear," and it is always very much adulterated. It is chiefly carried from the various ports on the Persian Gulf to Bombay, and so powerful is the smell of the new resin that special vessels have to be employed in the trade. The whole plant is strongly impregnated with the odour of asafœtida; in the regions of its growth it is used as a fresh vegetable, the inner portion of the full-grown stem being regarded as a luxury. The gum-resin itself is very highly relished as a condiment in India and Persia, and it is in demand in France for use in cookery. In Great Britain it is only employed in medicine, being of high value in spasmodic and convulsive diseases, such as hysteria, infantile convulsions, &c., but its offensive odour is a great bar to its use.

ASBEN, a country of Central Africa, known also as AIR, which see.

ASBESTOS, or ASBESTUS (from ἄσβεστος, *unconsumable*), is a variety of the amphibole or hornblende family of minerals, and akin to tremolite, actinolite, and common hornblende. The chemical composition of the whole family is chiefly silica, magnesia, alumina, and ferrous oxide, but varies considerably. Those containing most iron are most easily fused. Asbestos consists of fine crystalline elastic fibres, with a silky lustre, varying in colour from white to grey and green, and derives its name from being specially indestructible by fire. A single fibre of it fuses to a white enamel, but in the mass it is capable of resisting ordinary flame, and has on this account been regarded from ancient times as a most interesting substance. Woven into cloth it forms a fireproof texture, which, to be purified, requires only to be thrown in the fire; gloves, napery, towels, handkerchiefs, and even dresses have been woven of it, and it is said that the ancients used to wrap the bodies of their dead in asbestos cloth to keep their ashes separate from those of the surrounding funeral pile. There are several varieties of asbestos:—(1.) *Amianthus* is the rarest and most delicate kind, its fibres being beautifully white, flexible, long, and regularly laid. It is found in the centre of the older crystalline rocks, in the Pyrenees, the Alps of Dauphiny, on Mount St Gotthard, in North America, in the serpentine of Sweden, in the Ural Mountains, Silesia, and New South Wales. But the most beautiful specimens come from Tarantaise, in Savoy, and from Corsica, where it is somewhat abundant. (2.) *Common Asbestos* is not so light, either in colour or weight, as amianthus, and is more splintery, inflexible, and irregular in structure. It fuses with difficulty before the blow-pipe into a black scoria. It is found in serpentine rocks in Anglesea, in Cornwall, and also in several parts of Scotland, as Glenelg, in Inverness. (3.) *Mountain leather* and *Mountain cork* are other varieties, where the fibres are less flexible and regular than in either of the above. Their colour is brown or a dirty white. Mountain leather is in thin flexible sheets, and mountain cork is so named from being not unlike common cork, and so light as to swim on water. It is found in Lanarkshire. (4.) *Mountain wood* is a soft, tough, opaque, brownish-coloured variety of asbestos, much heavier than the last, and melting to a black slag before the blow-pipe. It is found in Tyrol, in Dauphiny, and in Scotland at Glen Tilt, Portsoy, and Kildrummy.

It has been often proposed to employ asbestos in the manufacture of fireproof goods, and it was at one time thought that an important industry would grow out of this application. In early times the art of weaving amianthine cloth was its chief application, and was much valued. It was accomplished by weaving the fibres along with those of flax, and then heating the cloth in a furnace to destroy the flax. It is said that Charlemagne had an amianthine tablecloth, which he used to have thrown into the fire after dinner for the astonishment of his guests. Chevalier Aldini, of Milan, is said to have had a complete dress—cap, gloves, tunic, and stockings—made of asbestos cloth, and to have made very successful experiments with it by way of testing its protective power for firemen. Advantage has also been taken of its qualities for the performance of clever tricks of fire-handling. Paper has been manufactured from asbestos, and would prove invaluable, in case of fire, for charters and other important documents, were it not that the paper is rather tender for use, and that the writing disappears after a red heat. Its feeble consistency has proved the chief obstacle to its use in textile fabrics. More success has attended its employment for fireproof roofing and flooring, for non-conducting envelopes of steam pipes, and for the packing in fireproof safes. Lately it has been proposed to use it for piston-packing in steam engines, it having been found to exceed in durability any material hitherto employed—a matter of importance, especially in the case of marine engines that have to be at work night and day on long voyages.

ASCALON, now ASKULAN, one of the five chief cities of the Philistines, on the coast of the Mediterranean, 12 geographical miles N. of Gaza. It was a well-fortified town, and the seat of the worship of Derceto. Though situated in the nominal territory of the tribe of Judah, it was never for any length of time in the possession of the Israelites. After the fall of the Macedonian empire, it became, like the rest of Phœnicia, tributary alternately to Syria and Egypt. Herod the Great was a native of the city, and added greatly to its beauty; but it suffered severely in the later wars of the Romans and Jews. It again became a flourishing and important place, and from the 4th to the 7th century was the seat of a bishopric. During the first Crusade a signal victory was gained by the Christians in the neighbouring plain on the 15th August 1099; but the city remained in the hands of the caliphs till 1157, when it was taken by Baldwin III., king of Jerusalem, after a siege of five months. By Baldwin IV. it was given to his sister Sibylla, on her marriage with William of Montferrat in 1178. When Saladin (1187) had almost annihilated the Christian army in the plain of Tiberias, Ascalon offered but a feeble resistance to the victor. At first he repaired and strengthened its fortifications, but afterwards, alarmed at the capture of St Jean d'Acre by Richard Cœur de Lion in 1191, caused it to be dismantled. It was again restored in the following year by the English king, but only again to be abandoned. From this time Ascalon lost much of its importance, and at length, in 1270, its fortifications were totally destroyed by Sultan Bibars, and its port filled up with stones. The place is now a desolate heap of ruins, with remains of its walls and fragments of granite pillars.

ASCENSION, a solitary island in the Atlantic Ocean, in lat. 7° 56′ S. and long. 14° 24′ W., about 7½ miles in length and 6 in breadth, with an area of 34 square miles, and within the immediate influence of the south-east trade-wind. It is one of the peaks of a submarine ridge which separates the northern and southern basins of the Atlantic. The whole character of the island is volcanic, and its surface is broken into mountains, hills, and ravines. Towards the south-east, the Green Mountain, the highest in the island, rises 2870 feet above the level of the sea, while the plains or table-lands surrounding it vary in height from 1200 to 2000 feet. On the north side they sweep gradually down towards the shore; but, on the south, they terminate in bold and lofty precipices. Steep and rugged ravines intersect the plains, opening into small bays or coves on the shore, fenced with masses of compact and cellular lava; and all over the island are found the usual products of volcanic action. The chief productions of the island are green vegetables. Ascension has long been noted for the abundance of turtle and turtle eggs found on its shores, the season lasting from December to May or June. The coasts abound with a variety of fish of excellent quality, of which the most important are the rock-cod, the cavalha, the conger-eel, and the "soldier." The wild animals are guinea-fowl, goats, cats, rats, and land-crabs; but the goats have been almost exterminated to make way for sheep and cattle. The air is clear and light, and the climate remarkably healthy. The island was discovered by the Portuguese navigator, Juan de Nova, on Ascension day 1501; but remained uninhabited till after the arrival of Napoleon at St Helena (1815), when it was taken possession of by the British Government. The garrison, with their retainers, resided in George Town, on the north-west coast, which is abundantly supplied with fresh water from a magnificent cistern capable of containing 1700 tons of water, supplied by means of iron pipes from springs in the Green Mountain, 6 miles distant, which were reached by boring in 1830. Ascension is found useful as a station and rendezvous for the vessels employed on the coasts of Africa and Brazil; and letters were formerly often left by passing ships in a crevice in one of the rocks. Population in 1871, 27. (See Darwin's *Observations on Volcanic Islands* and *A Naturalist's Voyage.*)

ASCENSION DAY, a festival of the church, held forty days after Easter, or ten days before Whit Sunday, in memory of Christ's ascension into heaven forty days after his resurrection.

ASCETICISM, from Greek ἄσκησις, meaning the exercise or training to which the athletes subjected themselves when preparing for the games or contests, is used metaphorically to denote the habitual practice of exercising restraint over, or subduing, the bodily desires and affections which tend to lower objects, in order thereby to advance in the higher life of purity and virtue. It is the means by which the mind withdraws itself from the hindrances and temptations of the world, and clears its vision for what is spiritual and true. In its lowest stage it consists in the mortification of the flesh by fasting, penance, and the like; but in a higher sense it involves the uprooting of all worldly or temporal desires, and withdrawal from the natural relations of life. The origin of such a peculiar aspect of thought or mode of action is to be found in the wide-spread idea, not wholly Oriental, that in Unity or Identity alone is true goodness and happiness, while in Multiplicity or Difference is evil and misery. Unity is but the abstract expression for God, the Absolute, or Spirit, and Multiplicity for Matter, in which both Orientals and Greeks thought to find the origin of evil. Now, in man exist both spirit, which is the shadow of or emanation from the divine, and the body, with its various desires and passions, which is of the nature of matter, and therefore in itself evil. True happiness—nay, true life for man—consists in contemplation of God, absorption into the divine unity and essence, and this ecstatic vision can only be attained by the cultivation of the spirit, and the mortification of the body. The desires and passions must be subdued, rooted up, and the means recommended are solitude, poverty, celibacy, fasting, and penance. We find, accordingly, that in all nations, those who seek divine illumination prepare themselves by these means. In this respect the Hindoo fakirs, jogis, dervishes, and gymnosophists, and the numerous sect of the Buddhists, are at one with the Hebrew prophets, Nazarites, and Chasidim, and with the priests of the Grecian mysteries. In most of the Greek schools of thought, however, asceticism had less a mystical and religious than a moral and practical bearing. Even the solitude and abstinence practised by the Pythagoreans were connected partly with their theory of metempsychosis, but mainly with their ethical training. Socrates, who called temperance, or self-restraint, the chief of virtues, had in view only the higher ethical life of the human spirit; and the Cynics and Stoics, who carried out his doctrine to an extreme, endeavoured to stifle the natural desires, and violate the natural relations of life, in order to realise their ideal of a wise and self-sufficing man of virtue. In Plato, however, appears very prominently the idea of matter as in itself evil and hostile to the divine; and among the neo-Platonic and neo-Pythagorean schools of Alexandria, who draw mainly from him, the doctrine and practice of a mystical and religious asceticism were essentially involved in their philosophical systems. About the same time similar principles had taken root among the Jews, and appeared in Palestine among the Essenes (by some supposed to be an offshoot from the Chasidim), in Egypt among the Therapeutæ. Into the heart of this circle of ideas Christianity entered, it incorporated many of them, and lent additional strength to the principle of asceticism in its higher signification. The deep sense of the nothingness of temporal phenomena when compared with spiritual realities, the conviction that in this world believers are but pilgrims, exposed to many temptations through the weakness of the flesh, in which is the origin of sin, and the many expressions which seemed to imply that riches and the ties of marriage were real hindrances in the Christian life, contributed to strengthen the already powerful tendency towards ascetic practices. Accordingly, in the early church celibacy and poverty, with occasional fasting and penance, were commonly recommended as means for the attainment of true virtue and communion with God, and such practices soon began to be looked upon as having a special merit in themselves. The natural consequence was that certain enthusiasts—such as Paul of Thebes, Anthony, and Simeon Stylites—vied with each other in their fanatical asceticism, withdrawing to the desert, and spending their lives in self-mortification. The persecutions of the church, which drove the Christians together, and the introduction of cenobitism by Pachomius in the 4th century, gave rise to monasticism, in which, for the first time, asceticism was reduced to an organised system. But the constant reforms required to preserve the purity of the monastic life, and the continuous protests against the whole practice, which began in the 11th century with such men as Peter of Bruis and Henry of Lausanne, and culminated in the Reformation, demonstrated the weakness of the foundation on which the system had been built. Asceticism, meanwhile, was not confined to the church, but had spread through the heretical and religious sects which sprang up alongside of it. The Ebionites and Gnostics inculcated the subjection of the body to the spirit; the new religion of Mani advocated the absolute withdrawal of all desires from the world; and among the followers of Mahomet, one sect, the Persian Sufis, specially distinguished themselves by their practice of abstinence and solitary meditation. Even in modern times, although ascetic practices have been modified, traces of the idea on which they rest are not wanting. The principles of the Quaker Society, of the Methodists, of the Communist bodies in America,—*e.g.*, the Shakers,—and other enthusiasts, are modifications, more or less pronounced, of the ascetic way of thinking.

ASCH, a town of Bohemia, in the circle of Eger, at the foot of the Hainberg, with a population of upwards of 9000, carrying on extensive manufactures of woollen, cotton, and other fabrics, as well as of paper, leather, and beer. The district of Asch, with an area of 42 square miles, was originally an immediate dependency of the empire, but has been since 1331 a fief of the Bohemian crown, and since 1770 incorporated with the kingdom. It is now held by the Zedtwitz family.

ASCHAFFENBURG, a town in the government of Lower Franconia, in the kingdom of Bavaria, at the confluence of the Aschaffa with the Maine, near the foot of the Spessart-Wald. Its chief buildings are the Johannisburg, built (1605–14) by Archbishop Sweikard of Kronberg, which contains a library, with a number of *incunabula*, a collection of engravings and paintings, the *Stiftkirche*, or cathedral, founded in 980 by Otto of Bavaria, in which are preserved various monuments by the Vischers, and a sarcophagus, with the relics of St Margaret (1540), the Capuchin hospital; a theatre, which was formerly the house of the Teutonic order; and several mansions of the German nobility. The town, which has been remarkable for its educational establishments since the 10th century, has a gymnasium, lyceum, seminarium, and other schools. The grave of Clemens Brentano (d. 1842) and his brother Christian (d. 1851) is in the churchyard near the Wennebach gate; and Wilhelm Heinse (d. 1803) is buried in the town. Cloth and stained paper are the chief manufactures; and the trade is principally in wood. The 10th and 23d Roman legions had their station at Aschaffenburg, and on the ruins of their *castrum* the Frankish mayors of the palace built a castle. Bonifacius erected a chapel to St Martin, and founded a Benedictine monastery. The stone bridge over the Maine was built by Archbishop Willigis in 989. Adalbert increased the importance of the town in various ways about 1122. In 1292 a synod was held there, and in 1474 an imperial diet, preliminary to that of Vienna, in which the famous concordats were decided, which have therefore been sometimes called the Aschaffenburg concordats. The town suffered greatly during the Thirty Years' War, being alternately held by the various belligerents. In 1842–9, King Louis built himself a country house to the west of the town, called the *Pompeianum*, from being an imitation of the house of Castor and Pollux at Pompeii. In 1866 the Prussians inflicted a severe defeat on the Austrians in the neighbourhood. Population, 9212.

The principality of Aschaffenburg, deriving its name from the city, comprehended an area of 336 geographical square miles. It formed part of the electorate of Mentz, and in 1803 was made over to the archchancellor, Archbishop Charles of Dalberg. In 1806 it was annexed to the grandduchy of Frankfort, and in 1814 was transferred to Bavaria, in virtue of a treaty concluded 19th June between that power and Austria. Conjointly with Lower Franconia, it now forms a circle of the kingdom of Bavaria.

ASCHAM, Roger, a very distinguished scholar and writer, was born at Kirby Wiske, a village in Yorkshire, near Northallerton, about the year 1515. John Ascham, his father, was house-steward in the family of Scroop, and by his wife Margaret was connected with several respectable families. A short time before his death, Sir Anthony Wingfield having conceived a predilection for his third son Roger, took him into his family, and extended his bounty so far as to give him the advantage of a private education along with his own sons. Under a domestic tutor he made a rapid progress in classical learning, and early discovered a great partiality for reading. The superiority of genius and docility of temper which he constantly displayed induced his patron to send him to St John's College, Cambridge, in the year 1530.

The revival of Greek and Roman literature at the period Ascham entered upon his studies was peculiarly favourable to the natural bent of his inclination. A desire of excelling uniformly influenced his conduct; and, adopting the maxim *Qui docet discit*, he began to teach boys the rudiments of the Greek language, as soon as he was acquainted with the elementary parts himself. His plan was approved by Pember, and under the direction of this valued friend he soon became acquainted with the best Greek and Latin authors. He devoted himself particularly to Cicero and Cæsar, and from his constant study of these writers acquired the elegant Latin style which proved so honourable and so advantageous in the after part of his life. Ascham took his degree of Bachelor of Arts in his 18th year, and was chosen fellow of the college about a month afterwards. The favourable disposition, however, which he manifested towards the reformed religion was no small obstacle in the way of his preferment. He was admitted Master of Arts in the year 1537, and about this period he began to act in the capacity of a tutor.

His reputation for Greek learning soon brought him many pupils, several of whom afterwards rose to considerable eminence. Of these one of the most distinguished was William Grindall, who obtained the station of master of languages to the Lady Elizabeth, upon the recommendation of Sir John Cheke. The reason why Ascham himself was not appointed to that honourable office is not known; but his partiality for the university seems, from a hint in one of his letters, to have been the cause. At that period there was no particular chair appropriated to the Greek language, but Ascham was appointed by the university to read lectures upon that language in the schools. A dispute arose in the university at that time about the pronunciation of the Greek language, in which Ascham first opposed the method observed by Sir John Cheke and Sir Thomas Smith; but, upon more mature deliberation, he adopted that method, which has ever since been practised in the English schools. Both on account of the beauty of his handwriting, and the purity and elegance of his Latin, he was employed to write the public letters of the university. In 1544, on the resignation of Cheke, he obtained the appointment of university orator, an office which he retained with great reputation during the period he was connected with the university.

By the advice of his friend Pember, he turned his attention to the study of instrumental music, and thereby enlivened his leisure hours, and prepared his mind for renewed exertion. In his study he also amused himself with embellishing the pages of his manuscripts with beautiful drawings, and in the field he took part in the diversion of archery. The learned Ascham did not deem his labour improperly bestowed in writing a book entitled *Toxophilus*, in an age when the proper use of the bow was of more importance than for mere amusement. This work was written in a more natural, easy, and truly English diction than had hitherto been in use; and it also abounds with beautiful allusions and curious fragments of English history. Ascham candidly acknowledges that, being anxious to make the tour of Italy, which was then the great republic of letters, and particularly of Greek literature, he wished, by dedicating his book to the king, to obtain a pension to enable him to make that tour. It reflects credit on Henry VIII. that in the year 1545 he settled upon him an annual pension of £10, which Dr Johnson estimates at the value of £100. Upon the death of Henry this pension was renewed by Edward VI., to whom Ascham was afterwards appointed Latin secretary.

For some years he received an annual gratuity from Lee, archbishop of York, but the amount of it is not recorded; and, in 1548, upon the death of his pupil Grindall, preceptor to the Lady Elizabeth, his pupils and writings had acquired him such celebrity, that he was appointed to direct the studies of that princess. He successfully acquitted himself in that honourable charge; but two years after, from some unknown cause of dissatisfaction, he returned to the university, having taken an abrupt leave of the princess. This conduct of his did not greatly affect his favour with royalty; for in the same year he was recalled to court, and appointed secretary to Sir Richard Morisine, ambassador to the Emperor Charles V. On his way to London he paid a visit to Lady Jane Grey, whom he found in her chamber reading Plato's *Phædo*, in Greek, "and that," says he, "with as much delight as some gentlemen would read a merry tale in Boccace," while the duke and duchess, and the rest of the household, were hunting in the park.

In the character of secretary to Sir Richard, besides aiding him in the management of his public affairs, he also conducted his private studies. During the mornings of four days in the week, he read with him a portion of Herodotus or Demosthenes, and in the evenings some pages of Sophocles or Euripides; on the other mornings he wrote the letters of public business, and on the evenings he either wrote his own private letters, or continued his diary and remarks. While Ascham was on his travels, he made a short excursion to Italy, but was much disgusted with the manners of the people, especially of the Venetians. After his return from that tour, he published a curious tract, entitled *A Report and Discourse of the Affairs and State of Germany*, &c.

Upon the death of Edward VI., Morisine was recalled, and Ascham returned to the university. The accession of a Catholic queen held out little prospect of advancement to a Protestant; but his fortune soon took a favourable turn, through the interest of Bishop Gardiner, who obtained for him the office of Latin secretary to the queen, with a salary of £20 a year, and permission to retain his university emoluments. The prudence of Ascham enabled him to act a respectable part, both under the government of Mary, and also in the most perilous situations during the reign of Elizabeth; and the readiness and elegance of his Latin style rendered him a useful member at court. He is reported to have written, during the course of three days, 47 letters to persons in the highest ranks of life.

When the crown passed to Elizabeth, it made little alteration in the condition of Ascham, who still retained his station. He spent several hours every day in reading the learned languages with the queen. Her proficiency was equal to his pains; and it might have been expected that his services would have received some reward more ample than £20 per annum, together with the prebend of Westwang. The allegation that the queen kept him poor because he was extravagant and addicted to cock-fighting, is hardly satisfactory.

In consequence of a conversation which took place in the apartment of secretary Cecil, upon the subject of education, Sir Richard Sackville, who was present, requested Ascham to write a book on the general subject of education. This work is entitled *The Scholemaster*, and contains many excellent directions to the instructors of youth, particularly with regard to teaching languages; where he recommends the method of double translation. It was published by his widow after his death. By too close application in composing a poem, which he intended to present to the queen on the New Year's day of 1569, he was seized with an illness which proved fatal. He died on the 23d of December 1568. His death was universally lamented, and the queen expressed her regret by saying, that "she would rather have lost £10,000 than her tutor Ascham." His epistles, which are valuable both on account of their style and historical information, were published after his death, and dedicated to the queen; the best edition is that of Elstob, published at Oxford in 1703. His English works were published in 4to, with a life by Dr Johnson, in 1771. This edition has been reprinted in 8vo. The whole works have been edited by Dr Giles, London, 1864–5. Of the *Toxophilus* and *Scholemaster* there are several reprints.

ASCHE, Rabbi, was the first and chief editor of the *Talmud*. He was born at Babylon in 353 A.D., and was in high repute among his contemporaries for his great learning. He began the Babylonian *Talmud*, and spent 30 years of his life at it. He left the work incomplete, and it was finished by his disciples, Rabbi Abina and Rabbi Jose.

ASCHERSLEBEN, a manufacturing city of Prussia, in the government of Magdeburg, formerly the chief town of a circle. It contains one Roman Catholic and five Protestant churches, a synagogue, a poor-house, an asylum for destitute children, and several schools. The discovery of coal in the neighbourhood has at once stimulated and altered its industries. In addition to the manufacture of woollen wares, for which it has long been known, there is now extensive production of vinegar, paraffin, potash, and especially beetroot-sugar; while the surrounding district, which was formerly devoted in great part to market-gardening, is now turned almost entirely into beetroot fields. Population, 16,741. Aschersleben was probably founded in the 11th century by Count Esika of Ballenstedt, the ancestor of the house of Anhalt, whose grandson, Otto, called himself count of Ascania and Aschersleben, deriving the former part of the title from his castle in the neighbourhood of the town. On the death of Otto III. (1315) Aschersleben passed into the hands of the bishop of Halberstadt, and at the peace of 1648, was, along with the bishopric, united to Brandenburg.

ASCLEPIADES, of Prusa in Bithynia, a celebrated physician, flourished at Rome in the end of the 2d century B.C. He travelled much when young, and seems at first to have settled at Rome as a rhetorician. In that profession he did not succeed, but he acquired great reputation as a physician. He founded his medical practice on a modification of the atomic or corpuscular theory, according to which disease results from an irregular or inharmonious motion of the corpuscles of the body. His remedies were, therefore, directed to the restoration of harmony, and in many cases were not unpleasant. He trusted most to changes of diet, accompanied by friction, bathing, and exercise, though he also employed emetics and bleeding. He recommended the use of wine, and in every way strove to render himself as agreeable as possible to his patients. His pupils were very numerous, and the school formed by them was called the Methodical. Asclepiades died at an advanced age from the effects of a fall.

ASCOLI (*Asculum Picenum*), the chief town and a bishop's see in the Italian province of Ascoli Piceno, situated on a rising ground on the river Tronto (*Truentus*), a few miles to the west of the Apennines, and commanding a large and fertile plain. It possesses a citadel, a cathedral, built on the site of a basilica erected by Constantine on the ruins of a temple of Hercules, a number of other churches, that of St Francesco dating from the 14th century, and remains of an ancient theatre, temples, &c. The city is built of travertine, and many of its public buildings were designed by Cola dell' Amatrice. It carries on considerable trade, and manufactures woollen cloth, leather, hats, majolica, glass wares, wax, rosoglio, confections, &c. Population, 22,937.

Asculum was the chief city of the Piceni, and a place of great strength. It was captured by P. Sempronius Sophus (268 B.C.), but afterwards took an important part in the Social War, and defied for a time the Roman consul Pompeius Strabo. It fell 89 B.C.; Judacilius, its gallant defender, put an end to his life; its magistrates were executed, and its inhabitants banished. At a later period it received a Roman colony, and recovered its prosperity. In 545 A.D. it was besieged by Totila. It was under the control of its bishops from the 3d to the 13th century; afterwards passed under the power of the Malatesti of Rimini; and in 1426 was annexed to the Papal States by Pope Martin V.

ASCONIUS PEDIANUS, Quintus, author of some commentaries on Cicero, was born probably a year or two before the Christian era, and died about 83 A.D. He is supposed to have been a native of Padua. Some minor works ascribed to him have been lost; all that are now extant consist of commentaries on some of Cicero's orations. These notes, written in very pure Latin, relate chiefly to matters of law, history, or antiquities, and are very valuable for the light they cast on some obscure parts of Cicero. As the commentaries on the Verrine orations deal more with questions of grammar, and do not show such purity of diction as the others, it has been conjectured that they are not the work of Asconius. The manuscript of the commentaries was discovered in 1416 by Poggio Bracciolini in the cellars of the convent of St-Gall. He took a copy of it, from which, as the original has been lost, all subsequent reprints have been taken. The best recent edition is by Orelli and Baiter, forming part of their large edition of Cicero's works. See also Madvig, *De Asconii Pediani Commentariis Disputatio*, Copenhagen, 1828.

ASELLI, Asellius, or Asellio, Gasparo (born 1581), a physician of Cremona, afterwards professor of anatomy at Pavia. He is best known by his important discovery of the *Lacteal Vessels*. His treatise (*De lactibus*, Milan, 4to) on this subject was posthumous, being published in 1627, a year after his death.

ASGARD (from *As*, god, and *gard*, home or hall), the home of the Æsir, *q.v.*, the Olympus of northern mythology. The city of Asgard is fabled to have been built on the highest part and in the middle of Ida's plain, which is the very centre of the universe. Here the Æsir erected a court for themselves with seats for twelve, and one high seat for Odin, the All-father, also a lofty abode for the goddesses, called Vingolf. They worked diligently, played at games, were rich in gold and all precious things, and happy, till three maidens from Jotunheim, the giants' world, crossed Ida's plain, and entered Asaheim, when corruption spread amongst its inmates. Asgard had many mansions, the largest and noblest of which was Gladsheim; whilst another, not so spacious, but the fairest of all, and brighter than the sun, was called Gimli. This will stand when both heaven and earth have passed away, and will be the habitation of all good and upright men through eternity. When the Æsir created men, and placed them in Midgard, they connected the latter with Asgard by a bridge, Bifrosh, known to mortals as the rainbow, which also leads to the sacred fountain of Urd, by the ash Yggdrasil, where the gods of Asgard take council together. For the other parts of Asgard, which are closely interwoven with the history of the creation of the world and of mankind, as taught in the Odinic faith, the reader is referred to MYTHOLOGY, in which the subject is treated more at length. The historical explanation of Asgard, as given by the early northern authorities, is that, in the country called Asaheim to the east of Tanagvise (the Tanais or Don) in Asia, there was a city, Asgard, in which ruled a great chief, known as Odin or Woden, who presided over the religious sacrifices which were held there. At that time the Roman generals were marching over the world, and reducing nations to subjection, and Odin, foreknowing that he and his posterity would occupy the northern lands, and unwilling to encounter the Romans, left Asaheim with a vast multitude of followers, and wandered first westward to Garderike (Russia), and afterwards to Saxland (North and East Germany). After some time he proceeded northward, till at length he came to the Malar Lake in Sweden, where he settled at a place known as Sigtuna, the present Upsala. His twelve diar, or chief priests, in the course of time founded states for themselves, and everywhere set up the laws and usages which they had followed in Asaheim. Here we have an historical link with the mythic story of Odin's halls in Asgard, and his twelve attendant Æsir; but we have no means of fixing the date of the events referred to. It has been conjectured that Odin may have lived at the time when Mithridates Eupator was defying the armies of Rome, 120-80 B.C.; and that, to avoid subjection to either power, he and other Sarmatian or Caucasian chiefs left their settlements on the Black Sea, and wandered forth in search of new and independent homes, to the north and west of the primary Asiatic seat of their tribes. It is not improbable that traditionary records of such earlier migrations had lingered among the people dwelling on the shores of the Euxine, for it is certain that, whatever may be the age of Odin's appearance in Scandinavia, previous waves of population had passed from the Black Sea to the Baltic, and cleared the way for the reception of that highest phase of Aryan civilisation brought to Northern Europe by Odin and his followers.

ASGILL, JOHN, an eccentric writer who flourished during part of the 17th and 18th centuries. The exact date of his birth is uncertain. He was bred to the law, and gained considerable reputation, not only by his skill in his profession, but from his first published writings. These consisted of two pamphlets—the first advocating the establishment of some currency other than the usual gold and silver, the second on the registry for titles of lands. His affairs, however, became embarrassed, and in 1699, when a commission was appointed to settle disputed claims in Ireland, he set out for that country, attracted by the hopes of practice. Before leaving London he put in the hands of the printer a tract, entitled *An Argument proving that, according to the Covenant of Eternal Life revealed in the Scripture, Man may be translated from hence into that Eternal Life without passing through Death.* The fame of this extraordinary pamphlet, in which Asgill spoke of dying as an unnecessary and foolish custom, preceded the author, and was of material service in securing his professional success. He amassed money, and purchased an estate, which unfortunately involved him in a lengthy litigation. In 1703 he took his seat in the Irish Parliament, but was dismissed after four days on account of his so-called blasphemous pamphlet. In 1705 he sat in the English Parliament for Bramber, but in 1707 he was expelled, nominally on account of his unlucky pamphlet, but really, perhaps, because of his debts. The remainder of his life he spent in the Fleet and King's Bench prisons, in one of which he died in 1738. He wrote a number of pamphlets on the Pretender and on the Hanoverian succession. Several of his tracts were collected, and published in London, 1715.

ASH (French, *Frêne*, German, *Esche*) is the name given to several kinds of trees. The taller or common ash (*Fraxinus excelsior*) belongs to the Natural Order *Oleaceæ*, the olive family. It is distinguished by its fruit, which is dry and winged. Normally the fruit should be two-celled and two-seeded; but generally, by abortion, there is only one cavity and one seed. The Hebrew word *Oren*, translated ash in Isaiah xliv. 14, cannot refer to an ash tree, as that is not a native of Palestine, but probably to the Syrian pine (*Pinus halepensis*). The ash is indigenous in Europe, and also extends to Asia. The tree is distinguished for its height and contour, as well as for its graceful foliage. It is one of the most useful of British trees as regards both timber and rapidity of growth. The tree attains a height of from 50 to 80 feet, and flowers in March and April, before the leaves are developed. It thrives best in a dry loamy soil, and, as it exhausts the soil in which it grows, it injures plants growing near it. The flowers grow in clusters, but are not showy. The leaves are compound, and unequally pinnate. A variety of ash, called *Fraxinus heterophylla*, diverse-leaved, has simple leaves. Another variety of ash is met with in which the branches are pendulous and weeping. Sometimes this variety is grafted on the tall stem of the common ash, so as to produce a pleasing effect. It is said that the weeping variety was first observed at Gamlingay, in Cambridgeshire. A variety also occurs with curled leaves, and another with warty stems and branches, called *Fraxinus verrucosa*. In Europe there is also a small-leaved ash, called *Fraxinus parvifolia*. In America there are several additional species—such as *Fraxinus americana*, the white American ash; *F. pubescens*, the black ash; and *F. sambucifolia*, the winter ash. Another plant which bears the name of ash is *Fraxinus Ornus*, or, more properly, *Ornus europœa*, the flowering or manna ash. Another species is *Ornus rotundifolia*, the round-leaved manna ash. The manna ash is a small tree found in Italy, and extending to Switzerland, South Tyrol, Hungary, Greece, Turkey, and Asia Minor. It also grows in the islands of Sicily, Corsica, and Sardinia. It blossoms early in summer, producing numerous clusters of whitish flowers. The word manna was first applied to the food supplied miraculously to the Israelites in the desert, but what it was cannot be determined. The name is now given to various saccharine exudations. The manna of commerce is collected almost entirely in Sicily from the manna ash. In order to get it, transverse cuts are made deep into the bark, so as to allow the manna to exude. The best kind is called "flake" manna. It consists of manna sugar, or mannite. The mountain ash belongs to a totally different family from the common ash. It is called *Pyrus aucuparia*, and belongs to the Natural Order *Rosaceæ*, and the tribe *Pomeæ*, which includes also apples, pears, &c. Its common name in Scotland is the rowan-tree, and it is well known by its succulent scarlet fruit. Pear trees are sometimes grafted on the mountain ash. The name of poison ash is given to *Rhus venenata*, belonging to the *Anacardiaceæ* (Cashew family). The bitter ash of the West Indies is *Simaruba excelsa*, which belongs to the Natural Family *Simarubaceæ*. The Cape ash is *Ekebergia capensis*, belonging to the Natural Order *Meliaceæ*. The prickly ash, *Xanthoxylon fraxineum*, belongs to the Natural Order *Xanthoxylaceæ*.

ASH-WEDNESDAY, the first day of Lent, is supposed to have received this name from a custom in the church of sprinkling ashes on the heads of penitents then admitted to penance. The early church did not commence Lent until the following Sunday; the additional days were probably included by Gregory the Great.

ASHANTEE, or SIANTI, a country in Western Africa, in the interior of the Gold Coast, the extent and population of which can only be approximately given. Stretching from lat. 5° to 9° N., and from long. 0° to 4° W., it comprises about 70,000 English square miles, and its population has been variously stated at from 1,000,000 to 3,000,000.

Tradition represents the Ashantees as deriving their origin from bands of fugitives, who, two or three centuries ago, were driven before the Moslem tribes migrating southward from the countries on the Niger and Senegal. Having cleared for themselves a region of impenetrable forest, they defended themselves with a valour which, becoming part of their national character, raised them to the rank of a powerful and conquering nation. They are supposed to be originally of the same race as the Fantees, nearer the coast, and speak the same language. The separation of Fantees and Ashantees is ascribed to a famine which drove the former south, and led them to live on *fan*, or herbs, while the latter subsisted on *san*, or Indian corn, &c. (whence the names Fantees and Santees).

Ashantee proper is covered with almost impenetrable forest, the routes through which consist merely of narrow winding tracts, where, though it is possible for a man to ride, or a palanquin to be carried, no waggon of any description could pass. Many of the trees attain splendid proportions, but the monotony is oppressive, and is hardly ever relieved by the sight of either bird or beast. The country round the towns in the interior, however, is cultivated with care, the fields being kept clean, and yielding in abundance grain, yams, vegetables, and fruits. The territory yields also a considerable quantity of gold. The Ashantees are skilful in several species of manufacture, particularly in weaving the great African fabric of cotton. Their pottery and works in gold also show skill, though surpassed by those produced in the more southern countries. A large quantity of silver-plate and goldsmith's work of great value and considerable artistic elaboration was found in 1874 in the king's palace of Coomassie, not the least remarkable objects being masks of beaten gold. The influence of Moorish art is perceptible in everything.

The government of Ashantee is a mixture of monarchy and military aristocracy; the lower orders being held in complete thraldom, and liable to be put to death or sold into slavery at the will of the chiefs. The king carries on all the ordinary administration of the state; but in questions relating to peace or war he is bound to consult the council of the caboceers or captains. Each of these caboceers keeps a little court, where he makes a profuse display of barbaric pomp. Polygamy is indulged in to an enormous extent, the king has a regular allowance of 3333 wives, but many of these are employed as guards or in menial services. The crown descends to the king's brother, or his sister's son, not to his own offspring.

The dreadful system of human sacrifice, practised among the Ashantees, is founded on a wild idea of piety towards parents and other connections—the chiefs fancying that the rank of their dead relatives in the future world will be measured by the number of attendants sent after them. There are two periods, called the great Adai and little Adai, succeeding each other at intervals of eighteen and twenty-four days, at which human victims, chiefly prisoners of war or condemned criminals, are often immolated to a monstrous extent. On the great Adai, which always falls on a Sunday, the king visits the burial-grounds of the princes and the royal mausoleum at Bantama, where the skeletons of his predecessors—their bones held together by links of gold—sit in grim mockery of state. Still more dreadful is the "custom" celebrated after the death of the king, or any member of the royal house.

Early in the 18th century the Ashantees first came under the notice of Europeans, through their successful wars with the kingdoms bordering on the maritime territory. Osai Tutu may be considered as the real founder of the Ashantee power. He either built or greatly extended Coomassie, the capital; he subdued the neighbouring state of Denkera (1719) and the Mahometan countries of Gaman and Banna, and extended the empire by conquests both on the east and west. At last he was defeated and slain (1731); but his successor, Osai Apoko, made further acquisitions towards the coast.

In 1800, Osai Tutu Quamina, an enterprising and ambitious man, who appears early to have formed the desire of opening a communication with white nations, became king. About 1807 two chiefs of the Assins, whom he had defeated in battle, sought refuge among the Fantees, the ruling people on the coast. On the refusal of the Fantees to deliver up the fugitives, he invaded their country, defeated them, and drove them towards the sea. At length they reached the town of Annamaboe, where there was then a British fort. The governor exhorted the citizens to come to terms, and offered to mediate; but they resolved to abide the contest. The result was the destruction of the town, with great slaughter of the inhabitants. The Ashantees failed, however, to storm the English fort, though the garrison was reduced from 24 to 8 men. A truce was agreed to, and the king refusing to treat except with the chief governor of Cape Coast, Colonel Torranne repaired to Annamaboe, where he was received with great pomp. A treaty was concluded by which the whole territory of Fantee, including Cape Coast Castle, was ceded by right of conquest to the Ashantee empire.

In 1817 the British Government sent Messrs James, Bowdich, and Hutchison on a mission to Coomassie. They were received with dignified politeness. After one or two harmonious interviews, the king advanced a claim for certain sums which the British were bound to pay to the native Governments, and which the Fantees had been accustomed to receive, for permission to hold fortified factories. Mr James proposed to refer this claim to the Government at Cape Coast Castle; whereupon the king broke out into uncontrollable rage, calling the deputies cheats and liars. Messrs Bowdich and Hutchison, thinking that the English interests and the safety of the mission were endangered, took the negotiation into their own hands. A treaty was concluded, by which all the king's demands were satisfied; and, after a residence of several months, they returned to Cape Coast.

The Government at home, though they demurred somewhat to the course that had been pursued, saw the wisdom of cultivating intercourse with this powerful African king. They sent out, therefore, to his court, as a fixed resident, M. Dupuis, who arrived at Cape Coast in January 1819. By that time the British local Government had been gained over to the interest of the Fantees. An insurrection had arisen in the interior of the Ashantee territory, respecting which exaggerated rumours had been listened to with blind credulity. Insulting messages were sent to the king, who was also informed that the inhabitants of Cape Coast were setting his authority at defiance, and were forming a wall to defend the town. The governor, on various pretences, detained M. Dupuis for some time; but at length, on the arrival of more than one ambassador from the king, allowed him to proceed. M. Dupuis set out on the 9th February 1820, and on the 28th arrived at Coomassie. After several confidential meetings with the king, a treaty was drawn up, which adjusted all the differences between the two parties. The king dismissed M. Dupuis with many marks of esteem and kindness, sending along with him two natives of distinction, to proceed as ambassadors to England. On his return to Cape Coast he found that the governor disowned the treaty, as betraying British interests and transferring to Ashantee the sovereignty of the Gold Coast. At the same time the Fantee party persuaded Sir George Collier to refuse to transport the Ashantee ambassadors to Britain.

M. Dupuis returned to England to represent the particulars to the Government, but an entire change meantime took place in the administration of British affairs in Africa. The African Company was abolished by Act of Parliament in 1821, and the forts and possessions transferred to the Crown. Sir Charles M'Carthy was invested with the government of all this range of coast. On his arrival in 1822 he adopted the Fantee policy, placed the town in a posture of defence, and formed alliances with the neighbouring tribes. It was hoped that the hostile attitude of the English would overawe the king, but he speedily declared open war.

After one or two unimportant successes, the British force was completely routed in Essamaco, near the boundary stream of the Prah, by a native army of about 10,000 men. Sir Charles M'Carthy was slain, and only 50 men, including two officers, returned to the castle. On the very day of this defeat Osai Tutu Quamina died, and was succeeded by Osai Okoto. The Ashantee army now marched upon Cape Coast, laying waste the country with fire and sword. At that place, however, detachments of reserve had united with the wrecks of the main corps, and vigorously prepared for defence. The king made repeated and desperate assaults, but at last sustained a signal defeat at Dudowah, on the 7th August 1826. In 1828 all public establishments were withdrawn by the British Government, and the chief power was transferred to a company of African merchants. In 1831 the king was obliged to purchase peace at the price of 6000 ounces of gold, and to send his son as a hostage to Cape Coast Castle. Since this event the Ashantee power has become extinct on the coast. By the treaty concluded at the end of the war, the river Prah was fixed as the boundary of the Ashantee kingdom, and all the tribes to the south of it were placed under British protection.

In 1843 the Crown resumed the government of the Gold Coast. Towards the end of 1852 the Ashantee monarch seemed disposed to interfere with the states absolved from his jurisdiction. Two Assin chiefs, who had revolted from Ashantee and joined the Fantee alliance, were discovered to be intriguing with the king of Ashantee; and that monarch, under pretext of making "custom" for the late chief of Denkera, crossed the Prah with a force of about 7000 men. These warlike movements naturally excited much uneasiness at Cape Coast Castle, but the negotiations of the authorities were successful in averting the storm. From 1853 to 1863 there was peace between Ashantee and the Government of Cape Coast Castle; but in the latter year disagreements broke out on account of a refusal to deliver up certain Ashantee refugees. In 1867 it was agreed that all the Dutch forts to the east of the Sweet River should be handed over to Britain in exchange for all the British forts to the west of that river. Unexpected difficulties, however, arose, which led the Dutch Government to offer all their possessions in that district to Britain, on certain commercial privileges being guaranteed to them. Hereupon the king of Ashantee objected to the transfer of Fort Elmina; but the superiority he alleged was completely disproved, and the proposal took effect on April 6, 1872.

Meanwhile another matter of dispute arose between the king and the English. Messrs Kuhne, Ramsayer, and Palmer, and a Frenchman named Bonnat, having been inveigled into captivity by an Ashantee chief, the British Government demanded their surrender, but this, on various pretexts, was obstinately refused by the king. War had for some time been imminent, and at length, on January 22, 1873, an Ashantee force crossed the Prah, and invaded the British protectorate. The importance of the invasion was soon recognised, not only by the local authorities, but by the Government at home; and measures were taken for the defence of the territory and the punishment of the assailants, which ultimately culminated in the despatch of Sir Garnet Wolseley as her Majesty's administrator, £800,000 being voted in parliament for the expenses of the expedition. On landing (October 2) at Cape Coast, he found that the Ashantee nation was in arms to the number of 40,000; the Fantee tribes were fragmentary and languid; and the country was extremely unhealthy for European troops. He determined, however, to march to Coomassie, and dictate terms to the king from his own capital. On January 20, 1874, the river Prah was crossed; on the 24th the Adansi hills were reached; on the 31st there was severe fighting at Amoaful; on the 1st of February Becquah was captured; and on the 4th the victorious army was in Coomassie. The town was full of Ashantee soldiers, but no attempt was made to turn the fortune of the war. As the rainy season was setting in, all possible haste was requisite; in two days, therefore, the homeward march was commenced, the city being left behind in flames. By the time that Fommanah was reached (February 13), the king sent his envoys to conclude a treaty, whereby he agreed, among other conditions, to pay 50,000 ounces of gold, to renounce all claim to homage from certain neighbouring kings, and all pretensions of supremacy over any part of the former Dutch protectorate, to promote freedom of trade, to keep open a road from Coomassie to the Prah, and to do his best to check the practice of human sacrifice. Besides coloured troops, there were employed in this campaign about 2400 Europeans, who suffered severely from fever and otherwise, though the mortality on the whole was slight. The success of the expedition was greatly facilitated by the exertions of Captains Glover, Butler, and Dalrymple, who effected important diversions with very inadequate resources.

See the works of Bowdich (1819), Dupuis (1824), Ricketts (1831), Beecham (1841), Stanley, Winwood Reade, Boyle, Brackenbury (1874).

ASHBURTON, a borough and market-town of England, in the county of Devon, 192 miles W.S.W. of London, and 18 from Exeter. It stands in a valley surrounded on every side by hills, at a short distance from the river Dart, and consists principally of one long street. The church of St Andrew is a handsome Gothic structure, built in the form of a cross, with a tower 90 feet high. Ashburton was the seat of one of the stannary courts. Before the Reform Act of 1832 it returned two members to parliament; from that time it returned one till 1868, when it was disfranchised. Population in 1871, 2335, principally employed in the manufacture of serge, or in the tin and copper mines and slate quarries in the vicinity.

ASHBY-DE-LA-ZOUCH, a market-town of England, county of Leicester, 17 miles north-west of Leicester, on the railway from that city to Burton. The town, which derives the adjunct to its name from the Norman family of La Zouch, consists principally of one long street. It contains six churches and chapels, and has a grammar school and several charity schools. The church of St Helen is a fine old building, containing the tombs of the Huntingdon family, and a "finger pillory." The Ivanhoe baths, erected in 1826, are much frequented for their saline waters, which, as containing bromine, are found useful in scrofulous and rheumatic complaints. To the south of the town are the extensive remains of Ashby Castle, built in 1480 by Sir William Hastings, ancestor of the earls of Huntingdon, who was created baron of Ashby-de-la-Zouch in 1461. It was one of the castles in which Mary Queen of Scots was confined. Population (1871), 7302, principally engaged in the manufacture of stockings, leather, malt, and firebricks, or in the coal and iron mines of the vicinity.

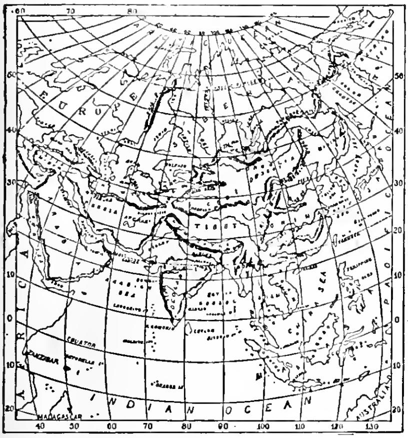
ASHDOD. See AZOTUS.

ASHFORD, a market-town of England, county of Kent, 12 miles south-west of Canterbury, and 53 from London. It is pleasantly situated on a gentle eminence near the junction of the upper branches of the river Stour, and is a chief station of the South-Eastern Railway. Many of its houses are well built and handsome; its principal street is nearly half a mile in length, and well paved and lighted. It has a fine old Gothic church, with a lofty, well-proportioned tower, and many handsome monuments. The free grammar school was founded by Sir Norman Knatchbull in the time of Charles I. Population of parish (1871), 8458.

ASHTON-UNDER-LYNE, or ASHTON, a parliamentary borough in the county of Lancaster, and hundred of Salford, on the northern bank of the river Tame, 6½ miles east of Manchester, and 197 from London. Like Manchester, it has had a rapid growth from an insignificant country town to a populous and thriving borough. Notwithstanding this it is well built, and contains many spacious streets and handsome public edifices. Among the latter are 4 large churches, 15 dissenting chapels, a spacious town-hall, and a very large and prosperous market-house. There are three banks, a savings-bank, a theatre, a mechanics' institute, and numerous week-day and Sunday schools. The corporation have built, at a cost of £16,000, a magnificent set of public baths. There are three newspapers published in the town. At a short distance to the north of the town are the infantry and cavalry barracks, erected in 1843 at a cost of £42,500, and the union workhouse, erected in 1851 at an expenditure of £12,000. A magnificent infirmary, built and endowed by public subscriptions, fronts the workhouse. A large public park is provided for the people midway between this and neighbouring borough of Stalybridge. A union hospital for infectious and other diseases has just been completed. The modern growth of Ashton dates from the introduction of the cotton trade in 1769. It enjoys many facilities for manufacturing industry, coal being very plentiful in the neighbourhood, four important railway lines passing through it, and canals connecting it with Manchester, Huddersfield, and Derbyshire. The town, though essentially modern, has an origin of great antiquity, and still exercises many of its ancient feudal customs and manorial privileges. It is divided into four wards, governed by a mayor, eight aldermen, and twenty-four councillors; and since the Reform Act of 1832 it has returned one member to the House of Commons. In 1821 it had a population of only 9222, which in 1851 had increased to 29,798, chiefly engaged in spinning cotton yarn and weaving ginghams and calicoes by machinery in the numerous large factories. Population of parliamentary borough in 1871, 37,389; of municipal borough, 31,984.

ASIA

Asia. 1. THIS division of the earth's surface embraces the north-eastern portion of the great mass of land which constitutes what is generally known as the Old World, of which Europe forms the north-western and Africa the south-western region.



Sketch Map of Asia.

Ancient geography. 2. Geography, in common with most of the other branches of human learning which have supplied the foundation of modern science, originated in Egypt and Greece, and its nomenclature naturally carries with it the stamp of the place where it had its birth. The earliest conceptions of geographical position were necessarily formed and expressed in relation to the region in which the ancient geographers lived and wrote; and the first steps in generalisation which recognised and distinguished the special characteristics of the countries and people grouped round the eastern end of the Mediterranean, and suggested the three great divisions of the Old World, attest the sagacity of the founders of geography, whose landmarks their successors still respect.

Origin of name. 3. Much doubt attaches to the origin of the words Europe, Africa, and Asia. Some of the earliest Greek geographers divided their known world into two portions only, Europe and Asia, in which last Libya (the Greek name for Africa) was included. Herodotus, who ranks Libya as one of the chief divisions of the world, separating it from Asia, repudiates as fables the ordinary explanations assigned to the names Europe and Asia, but confesses his inability to say whence they came. It would appear probable, however, that the former of these words was derived from an Assyrian or Hebrew root, which signifies the west or setting sun, and the latter from a corresponding root meaning the east or rising sun, and that they were used at one time to imply the west and the east. There is ground also for supposing that they may at first have been used with a specific or restricted local application, a more extended signification having eventually been given to them. After the word Asia had acquired its larger sense, it was still specially used by the Greeks to designate the country around Ephesus. The word Africa is the Latin substitute for the Greek Libya; its origin is obscure. It may have been a local name. It was long used with special reference to the country about Carthage, and this seems to have been the case even to the time of the Mahometan conquest. The idea of Asia as originally formed was necessarily indefinite, and long continued to be so; and the area to which the name was finally applied, as geographical knowledge increased, was to a great extent determined by arbitrary and not very precise conceptions, rather than on the basis of natural relations and differences subsisting between it and the surrounding regions.

Area. 4. The entire surface of the earth being about 196 millions of square miles in area (of which 51 millions are land, and 145 millions water), Asia contains about 17 millions of square miles, or say one-third of the whole of the dry land and one-twelfth part of the whole surface of the globe. Europe contains about $3\frac{1}{2}$ millions of square miles, or close upon one-fifth of the area of Asia; Africa, $11\frac{1}{2}$ millions; and the two Americas together, rather more than 15 millions. The remainder of the land belongs to Australia, the islands of the Eastern Archipelago and the Pacific, and the Antarctic regions.

Boundaries. 5. The northern boundary of Asia is formed by the Arctic Ocean; the coast-line falls between the 70th and the 75th parallels of N. lat., and so lies within the Arctic circle, having its extreme northern point in Cape Sievero-Vostochny (*i.e., north-east*), in lat. 78° N. On the south the coast-line is far more irregular, the Arabian Sea, the Bay of Bengal, and the China Sea, reaching about to the northern tropic at the mouths of the Indus, of the Ganges, and of the Canton river; while the great peninsulas of Arabia, of Hindostan, and Cambodia, descend to about the 10th degree of N. lat., and the Malay peninsula extends within a degree and a half of the equator. On the west the extreme point of Asia is found on the shore of the Mediterranean, at Cape Baba, in long. 26° E. from Greenwich, not far from the Dardanelles. Thence the boundary passes in the one direction through the Mediterranean, and down the Red Sea to the southern point of Arabia, at the Straits of Báb-el-mándeb, in long. 45° E.; and in the other through the Black Sea, and along the range of Caucasus, following approximately the 40th degree of N. lat. to the Caspian, whence it turns to the north on a line not far from the 60th meridian, along the Ural Mountains, and meets the Arctic Ocean nearly opposite the island of Nova-Zembla. The most easterly point of Asia is Cape Vostochnyii (*i.e., east*), in long. 190° E., at the entrance of Behring's Straits. The boundary between this point and the extremity of the Malay peninsula follows the coast of the Northern Pacific and the China Sea, on a line deeply broken by the projection of the peninsulas of Kamchatka and Corea, and the recession of the Gulfs of Okotsk, the Yellow Sea, Tonquin, and Siam.

Islands. 6. On the east and south-east of Asia are several important groups of islands, the more southern of which link this continent to Australia, and to the islands of the Pacific. The Kurile Islands, the Japanese group, Loo-choo, Formosa, and the Philippines, may be regarded as unquestionable outliers of Asia. Between the islands of the Malay Archipelago from Sumatra to New Guinea, and the neighbouring Asiatic continent, no definite relations appear ever to have existed, and no distinctly-marked boundary for Asia has been established by the old geographers in this quarter. Modern science, however, has indicated a line of physical separation along the channel between Borneo and the Celebes, called the Straits of Macassar, which follows acproximately the 120th meridian of E. long., to the west of which the flora and fauna are essentially Asiatic in their type, while to the south and east the Australian element begins to be distinctly marked, soon to become predominant. To this boundary has been given the name of Wallace's line, after the eminent naturalist who first indicated its existence.

Form of continent.

7. Owing to the great extent of Asia, it is not easy to obtain a correct conception of the actual form of its outline from ordinary maps, the distortions which accompany projections of large spherical areas on a flat surface being necessarily great and misleading. Turning, therefore, to a globe, Asia, viewed as a whole, will be seen to have the form of a great isosceles spherical triangle, having its north-eastern apex at Cape Vostochnyii, in Behring's Straits; its two equal sides, in length about a quadrant of the sphere, or 6500 miles, extending on the west to the southern point of Arabia, and on the east to the extremity of the Malay peninsula; and the base between these points, occupying about 60° of a great circle, or 4500 miles, and being deeply indented by the Arabian Sea and the Bay of Bengal on either side of the Indian peninsula. A great circle, drawn through Cape Vostochnyii and the southern point of Arabia, passes nearly along the coast line of the Arctic Ocean, over the Ural Mountains, through the western part of the Caspian, and nearly along the boundary between Persia and Asiatic Turkey. Asia Minor and the north-western half of Arabia lie outside of such a great circle, which otherwise indicates, with fair accuracy, the north-western boundary of Asia. In like manner a great circle drawn through Cape Vostochnyii and the extremity of the Malay peninsula, passes nearly over the coasts of Manchuria, China, and Cochin-China, and departs comparatively little from the eastern boundary.

Relative importance of geographical features.

8. Although for the purposes of geographical nomenclature, boundaries formed by a coast line—that is, by depressions of the earth's solid crust *below* the ocean level—are most easily recognised, and are of special convenience; and although such boundaries, from following lines on which the continuity of the land is interrupted, often necessarily indicate important differences in the conditions of adjoining countries, and of their political and physical relations, yet variations of the elevation of the surface *above* the sea level frequently produce effects not less marked. The changes of temperature and climate caused by difference of elevation are quite comparable in their magnitude and effect on all organised creatures with those due to differences of latitude; and the relative position of the high and low lands on the earth's surface, by modifying the direction of the winds, the fall of rain, and other atmospheric phenomena, produces effects in no sense less important than those due to the relative distribution of the land and sea. Hence the study of the mountain ranges of a continent is, for a proper apprehension of its physical conditions and characteristics, as essential as the examination of its extent and position in relation to the equator and poles, and the configuration of its coasts.

Tibeto-Himalayan mountains.

9. From such causes the physical conditions of a large part of Asia, and the history of its populations, have been very greatly influenced by the occurrence of the mass of mountain, which includes the Himalaya and the whole elevated area having true physical connection with that range, and occupies an area about 2000 miles in length and varying from 100 to 500 miles in width, between the 65th and 100th meridians east from Greenwich, and between the 28th and 35th degrees of N. lat. These mountains, which are the highest in the world, rise, along their entire length, far above the line of perpetual snow, and few of the passes across the main ridges are at a less altitude than 15,000 or 16,000 feet above the sea. Peaks of 20,000 feet abound along the whole chain, and the points that exceed that elevation are numerous, the highest hitherto measured being more than 29,000 feet above the sea. A mountain range such as this, attaining altitudes at which vegetable life ceases, and the support of animal life is extremely difficult, constitutes an almost impassible barrier against the spread of all forms of living creatures. The mountain mass, moreover, is not less important in causing a complete separation between the atmospheric conditions on its opposite flanks, by reason of the extent to which it penetrates that stratum of the atmosphere which is in contact with the earth's surface and is effective in determining climate. The highest summits create serious obstructions to the movements of nearly three-fourths of the mass of the air resting on this part of the earth, and of nearly the whole of the moisture it contains; the average height of the entire chain is such as to make it an almost absolute barrier to one-half of the air and three-fourths of the moisture; while the lower ranges also produce important atmospheric effects, one-fourth of the air and one-half of the watery vapour it carries with it lying below 9000 feet.

Their physical importance.

GEOGRAPHY.

10. This great mass of mountain, constituting as it does a complete natural line of division across a large part of the continent, will form a convenient basis from which to work, in proceeding, as will now be done, to give a general view of the principal countries contained in Asia.

Tibet.

11. The summit of the great mountain mass is occupied by *Tibet*, a country known by its inhabitants under the name of *Bod*, or *Bodyul*. *Tibet* is a rugged table-land, narrow as compared to its length, broken up by a succession of mountain ranges, which follow as a rule the direction of the length of the table-land, and commonly rise into the regions of perpetual snow; between the flanks of these lie valleys, closely hemmed in, usually narrow, having a very moderate inclination, but at intervals opening out into wide plains, and occupied either by rivers, or frequently by lakes from which there is no outflow and the waters of which are salt. The eastern termination of Tibet is in the line of snowy mountains which flanks China on the west, between the 27th and 35th parallels of latitude, and about on the 103d meridian east. On the west the table-land is prolonged beyond the political limits of Tibet, though with much the same physical features, to about the 70th meridian, beyond which it terminates; and the ranges which are covered with perpetual snow as far west as Samárkhand thence rapidly diminish in height, and terminate in low hills north of Bukhára.

Its extent.

Its mountains.

12. The mean elevation of Tibet may be taken as 15,000 feet above the sea. The broad mountainous slope by which it is connected with the lower levels of Hindostan contains the ranges known as the Himalaya; the names of Kouenlun, or Karakorum, have been given by some geographers to the northern slope that descends to the central plains of the Gobi, though these mountains are not locally known under those names, Kouenlun being apparently a Chinese corruption of some Turkish or Tibetan word, and Karakorum only one of the many passes that lead from Western Tibet to the northward.

Its climate and people.

13. The extreme rigour of the climate of Tibet, which combines great cold with great drought, makes the country essentially very poor, and the chief portion of it little better than desert. The vegetation is everywhere most scanty, and anything deserving the name of a tree is hardly to be found unless in the more sheltered spots, and then artificially planted. The population in the lower and warmer valleys live in houses, and follow agriculture; in the higher regions they are nomadic shepherds, thinly scattered over a large area.

China.

14. *China* lies between the eastern flank of the Tibetan

plateau and the North Pacific, having its northern and southern limits about on the 40th and the 20th parallels of N. lat. respectively. The country though generally broken up with mountains of moderate elevation, possesses none of very great importance apart from those of its western border. It is well watered, populous, and, as a rule, highly cultivated, fertile, and well wooded; the climate is analogous to that of southern Europe, with hot summers, and winters everywhere cold and in the north decidedly severe.

Indo-Chinese region.

15. From the eastern extremity of the Tibetan mountains, between the 95th and 100th meridians, high ranges extend from about lat. 35° N., in a southerly direction, which, spreading outwards as they go south, reach the sea at various points in Cochin-China, the Malayan peninsula, and the east flank of Bengal. Between these ranges, which are probably permanently snowy to about the 27th degree of N. lat., flow the great rivers of the Indo-Chinese peninsula, the Mekong, the Menám, the Sálwen, and the Irawády, the valleys of which form the main portions of the states of Cochin-China (including Tonquin and Camboja), of Siam (including Laos), and of Burmah. The people of Cochin-China are called *Anam*; it is probably from a corruption of their name for the capital of Tonquin, *Kechao*, that the Portuguese *Cochin* has been derived. All these countries are well watered, populous, and fertile, with a climate very similar to that of eastern Bengal. The geography of the region in which the mountains of Cochin-China and Siam join Tibet is still very imperfectly known, but there is no ground left for doubting that the great river of eastern Tibet, the Tachok-tsangpo, supplies the main stream of the Brahmaputra. The two great rivers of China, the Hoang-ho and the Yang-tse-kyang, take their rise from the eastern face of Tibet, the former from the north-east angle, the latter from the south-east. The main stream of this last is called Bri-chu in Tibet, and its chief feeder is the Ya-lung-kyang, which rises not far from the Hoang-ho, and is considered the territorial boundary between China and Tibet.

British India.

16. *British India* comprises approximately the area between the 95th and 70th meridians, and between the Tibetan table-land and the Indian Ocean. The Indian peninsula from the 25th degree of latitude southwards is a table-land, having its greatest elevation on the west, where the highest points rise to over 8000 feet, though the ordinary altitude of the higher hills hardly exceeds 4000 feet; the general level of the table-land lies between 3000 feet as a maximum and 1000 feet.

Great northern plain.

17. From the delta of the Ganges and Brahmaputra on the east to that of the Indus on the west, and intervening between the table-land of the peninsula and the foot of the Himalayan slope of the Tibetan plateau, lies the great plain of northern India, which rises at its highest point to about 1000 feet, and includes altogether, with its prolongation up the valley of Assam, an area of about 500,000 square miles, comprising the richest, the most populous, and most civilised districts of India. This great plain extends, with an almost unbroken surface, from the most western to the most eastern extremity of British India, and is composed of deposits so finely comminuted, that it is no exaggeration to say that it is possible to go from the Bay of Bengal up the Ganges, through the Punjab, and down the Indus again to the sea, over a distance of 2000 miles and more, without finding a pebble, however small.

Rivers.

18. The great rivers of Northern India—the Ganges, the Brahmaputra, and the Indus—all derive their waters from the Tibetan mountain mass; and it is a remarkable circumstance, that the waters of almost the whole of the summit of the plateau are carried off into British India between the 95th and 75th meridians, and that the only part of the drainage thrown off to the north, is that of the northern mountain slope.

Population and climate.

19. The population of India is very large, some of its districts being probably among the most densely peopled in the world. The country is generally well cleared; and forests are, as a rule, found only along the flanks of the mountains, where the fall of rain is most abundant. The more open parts are highly cultivated, and large cities abound. The climate is generally such as to secure the population the necessaries of life without severe labour; the extremes of heat and drought are such as to render the land unsuitable for pasture, and the people everywhere subsist by cultivation of the soil or commerce, and live in settled villages or towns.

Ceylon.

20. The island of *Ceylon* is distinguished from the neighbouring parts of British India by little more than its separate administration and the Buddhistic religion of its population. The highest point in Ceylon rises to about 9000 feet above the sea, and the mountain slopes are densely covered with forest. The lower levels are in climate and cultivation quite similar to the regions in the same latitude on the Malay peninsula.

Nicobars and Andamans.

21. Of the islands in the Bay of Bengal, the *Nicobar* and *Andaman* groups are alone worth notice. They are placed on a line joining the north end of Sumatra and Cape Negrais, the south-western extremity of Burmah. They possibly owe their existence to the volcanic agencies which are known to extend from Sumatra across this part of the Indian Ocean.

Laccadives and Maldives.

22. The *Laccadives* and *Maldives* are groups of small coral islands, situated along the 73d meridian, at no great distance from the Indian peninsula, on which they have a very slight and ill-defined political dependency.

High lands of Persia.

23. The portion of Asia west of British India, excluding Arabia and Syria, forms another extensive plateau covering an area as large as that of Tibet, though at a much lower altitude. Its southern border runs along the Arabian Sea, the Persian Gulf, the Tigris, and thence westward to the north-east angle of the Levant; on the north the high land follows nearly the 36th degree of N. lat. to the southern shore of the Caspian, and thence to the Black Sea and Sea of Marmora. *Afghánistán*, *Balúchistán*, *Irán* or Persia, *Armenia*, and the provinces of *Asia Minor*, occupy this high region, with which they are nearly conterminous. The eastern flank of this table-land follows a line of hills drawn a short distance from the Indus, between the mouth of that river and the Himalaya, about on the 72d meridian; these hills do not generally exceed 4000 or 5000 feet in elevation, but a few of the summits reach 10,000 feet or more. The southern and south-western face follows the coast closely up the Persian Gulf from the mouth of the Indus, and is formed further west by the mountain scarp which, rising in many points to 10,000 feet, flanks the Tigris and the Mesopotamian plains, and extends along Kurdistan and Armenia nearly to the 40th meridian; beyond which it turns along the Taurus range, and the north-eastern angle of the Mediterranean. The north-eastern portion of the Afghan table-land abuts on the Himalaya and Tibet, with which it forms a continuous mass of mountain between the 71st and 72d meridians, and the 34th and 36th parallels of N. lat. From the point of intersection of the 71st meridian with the 36th parallel of latitude, which falls nearly on the pass called *Hindu-kosh* (a name which has been extended by geographers to the ridge on which it is placed), an unbroken range of mountain stretches on one side towards the north-east, up to the crest of the northern slope of the Tibetan plateau, and on the other nearly due west as far as the Caspian. The north-eastern portion of this range is of

Afghanistan.

great altitude, and separates the head waters of the Oxus, which run off to the Aral Sea, from those of the Indus and its Cabul tributary, which, uniting below Peshâwar, are thence discharged southward into the Arabian Sea. The western part of the range, which received the name of Paropamisan Mountains from the ancients, diminishes in height west of the 65th meridian, and constitutes the northern face of the Afghan and Persian plateau, rising abruptly from the plains of the Turkoman desert, which lies between the Oxus and the Caspian. These mountains at some points attain a height of 10,000 or 12,000 feet. Along the south coast of the Caspian this line of elevation is prolonged as the Elburz range (not to be confused with the Elburz of the Caucasus), and has its culminating point in Demavend, which rises to 18,500 feet above the sea; thence it extends to the north-west to Ararat, which rises to upwards of 17,000 feet, from the vicinity of which the Euphrates flows off to the south-west, across the high lands of Armenia. Below the north-east declivity of this range lies Georgia, on the other side of which province rises the Caucasus, the boundary of Asia and Europe between the Caspian and Black Seas, the highest points of which reach an elevation of nearly 19,000 feet. West of Ararat high hills extend along the Black Sea, between which and the Taurus range lies the plateau of Asia Minor, reaching to the Ægean Sea; the mountains along the Black Sea, on which are the Olympus and Ida of the ancients, rise to 6000 or 7000 feet; the Taurus is more lofty, reaching 8000 and 10,000 feet; both ranges decline in altitude as they approach the Mediterranean.

Asia Minor.

Extent, climate, population.

24. This great plateau, extending from the Mediterranean to the Indus, has a length of about 2500 miles from east to west, and a breadth of upwards of 600 miles on the west, and nowhere of less than 250 miles. It lies generally at altitudes between 2000 feet and 8000 feet above the sea level. Viewed as a whole, the eastern half of this region, comprising Persia, Afghanistan, and Baluchistan, is poor and unproductive. The climate is very severe in the winter, and extremely hot in summer. The rainfall is very scanty, and running waters are hardly known, excepting among the mountains which form the scarps of the elevated country. The population is sparse, frequently nomadic, and addicted to plunder; progress in the arts and habits of civilisation is small. The western part of the area falls within the Turkish empire. Its climate is less hot and arid, its natural productiveness much greater, and its population more settled and on the whole more advanced.

Arabia and Syria.

25. The peninsula of *Arabia*, with *Syria*, its continuation to the north-west, have some of the characteristics of the hottest and driest parts of Persia and Baluchistan. Excepting the northern part of this tract, which is conterminous with the plain of Mesopotamia (which at its highest point reaches an elevation of about 700 feet above the sea), the country is covered with low mountains, rising to 3000 or 4000 feet in altitude, having among them narrow valleys in which the vegetation is scanty, with exceptional regions of greater fertility in the neighbourhood of the coasts, where the rainfall is greatest. In Northern Syria the mountains of Lebanon rise to about 10,000 feet, and with a more copious water supply the country becomes more productive. The whole tract, excepting south-eastern Arabia, is nominally subject to Turkey or Egypt, but the people are to no small extent practically independent, living a nomadic, pastoral, and freebooting life under petty chiefs, in the more arid districts, but settled in towns in the more fertile tracts, where agriculture becomes more profitable, and external commerce is established.

Turkistan.

26. The area between the northern border of the Persian high lands and the Caspian and Aral Seas is a nearly desert low-lying plain, extending to the foot of the north-western extremity of the great Tibeto-Himalayan mountains, and prolonged eastward up the valleys of the Oxus and Jaxartes, and northwards across the country of the Kirghiz and Kassaks, to the south-western border of Siberia. It includes *Bukhara*, *Khiva*, and *Turkistan* proper, in which the Uzbeg Turks are dominant, and for the most part is inhabited by nomadic tribes, who are marauders, enjoying the reputation of being the worst among a race of professed robbers. The tribes to the north, subject to Russia, are naturally more peaceable, and have been brought into some degree of discipline. In this tract the rainfall is nowhere sufficient for the purposes of agriculture, which is only possible by help of irrigation; and the fixed population (which contains a non-Turkish element) is comparatively small, and restricted to the towns and the districts near the rivers.

Pámir.

27. The most northern extremity of the elevated Tibeto-Himalayan mountain plateau is situated about on the 73d meridian east, and 39° N. lat. This region is known as *Pámir;* it has all the characteristics of the highest regions of Tibet, and so far fitly receives the Russian designation of steppe; but it seems to have no special peculiarities, and the reason of its having been so long regarded as a geographical enigma is not obvious. From it the Oxus, or Amu, flows off to the west, and the Jaxartes, or Sir, to the north, through the Turki state of Kokand, while to the east the waters run down past Kashgar to the central desert of the Gobi, uniting with the streams from the northern slope of the Tibetan plateau that traverse the principalities of *Yárkend* and *Khoten*, which are also Turki. Here the Tibetan mountains unite with the line of elevation which stretches across the continent from the Pacific, and which separates Siberia from the region commonly spoken of under the name of Central Asia.

Manchuria.

28. A range of mountains, called Stanovoi, rising to heights of 4000 or 5000 feet, follows the southern coast of the eastern extremity of Asia from Kamchatka to the borders of Manchuria, as far as the 135th meridian, in lat. 55° N. Thence, under the name of Yablonoi, it divides the waters of the river Lena, which flows through Siberia into the Arctic Sea, from those of the river Amur, which falls into the North Pacific; the basin of this river, with its affluents, constitutes *Manchuria.* Approximately at right angles to the last named range, another, known as the Khingan, extends between the 120th and 115th meridians, from the 55th to the 42d parallel of N. lat., east of which the drainage falls into the Amur and the Yellow Sea, while to the west is an almost rainless region, the inclination of which is towards the central area of the continent, which is *Mongolia.*

Mongolia

29. From the western end of the Yablonoi range, on the 115th meridian, a mountainous belt extends along a somewhat irregular line to the extremity of Pamir, known under various names in its different parts, and broken up into several branches, enclosing among them many isolated drainage areas, from which there is no outflow, and within which numerous lakes are formed. The most important of these ranges is the Thian-shan, or Celestial mountains, which form the northern boundary of the Gobi desert; they lie along the 42d and 43d parallels of N. lat., between the 75th and 95th meridians, and some of the summits are said to exceed 20,000 feet in altitude; along the foot of this range lie the principal cultivated districts of Central Asia, and here too are situated the few towns which have sprung up in this barren and thinly-peopled region. Next may be named the Ala-tau, on the prolongation of the Thian-shan, flanking the Sir on the north, and rising to 14,000 or 15,000 feet. It forms the barrier between the Issik-kul and Balkash lakes, the elevation of which is about 5000 feet. Last is the Altai, near the 50th parallel, rising to 10,000 or 12,000 feet, which separates the waters of the great rivers of Western Siberia from those that col-

lect into the lakes of North-west Mongolia, Zungaria, and Kalka. A line of elevation is continued west of the Altai to the Ural Mountains, not rising to considerable altitudes; this divides the drainage of South-west Siberia from the great plains lying north-east of the Aral Sea.

Gobi. 30. The central area bounded on the north and north-west by the Yablonoi Mountains and their western extension in the Thian-shan, on the south by the northern face of the Tibetan plateau, and on the east by the Khingan range before alluded to, forms the great desert of Central Asia, known as the Gobi. Its eastern part is nearly conterminous with South Mongolia, its western forms East Turkistan. It appears likely that no part of this great central Asiatic desert is less than 2000 feet above the sea-level. The elevation of the plain about Kashgar and Yarkend is from 4000 to 6000 feet. The more northern parts of Mongolia are between 4000 and 6000 feet, and no portion of the route across the desert between the Chinese frontier and Kiákhta is below 3000 feet. The precise positions of the mountain-ridges that traverse this central area are not properly known; their elevation is everywhere considerable, and many points are known to exceed 10,000 or 12,000 feet.

Climate and people. 31. In Mongolia the population is essentially nomadic, their wealth consisting in herds of horned cattle, sheep, horses, and camels. The Turki tribes, occupying Western Mongolia, are among the least civilised of human beings, and it is chiefly to their extreme barbarity and cruelty that our ignorance of Central Asia is due. The climate is very severe, with great extremes of heat and cold. The drought is very great; rain falls rarely, and in small quantities. The surface is for the most part a hard stony desert, areas of blown sand occurring but exceptionally. There are few towns or settled villages, except along the slopes of the higher mountains, on which the rain falls more abundantly, or the melting snow supplies streams for irrigation. It is only in such situations that cultivated lands are found, and beyond them trees are hardly to be seen.

Siberia. 32. The portion of Asia which lies between the Arctic Ocean and the mountainous belt bounding Manchuria, Mongolia, and Turkistan on the north, is Siberia; it is almost equal in area to the whole of Europe. It is for the most part a low-lying diluvial plain, with a nearly level or slightly undulating surface, which extends eastwards from the Ural Mountains almost to Kamchatka. Beyond the 125th meridian the plain is more broken by hills. The extremes of heat and cold are very great. The rainfall, though not heavy, is sufficient to maintain such vegetation as is compatible with the conditions of temperature, and the surface is often swampy or peaty. The mountain sides are commonly clothed with pine forests, and the plains with grasses or shrubs. The population is very scanty; the cultivated tracts are comparatively small in extent, and restricted to the more settled districts The towns are entirely Russian. The indigenous races are nomadic Mongols, of a peaceful character, but in a very backward state of civilisation. The Ural Mountains do not exceed 2000 or 3000 feet in average altitude, the highest summits not exceeding 6000 feet, and one of the passes being as low as 1400 feet. In the southern half of the range are the chief mining districts of Russia. The Ob, Yenisei, and Lena, which traverse Siberia, are among the largest rivers in the world.

Malay islands. 33. The southern group of the Malayan Islands, from Sumatra to Java and Timor, extends in the arc of a circle, between the 95th and 127th meridians, and from the 5th degree of N. to the 10th degree of S. lat. The central part of the group is a volcanic region, many of the volcanoes being still active, the summits frequently rising to 10,000 feet or more.

34. *Sumatra*, the largest of the islands, is but thinly peopled; the greater part of the surface is covered with dense forest, the cultivated area being comparatively small, confined to the low lands, and chiefly in the volcanic region near the centre of the island. *Java* is the most thickly peopled, best cultivated, and most advanced island of the whole Eastern Archipelago. It has attained a high degree of wealth and prosperity under the Dutch Government. The people are peaceful and industrious, and chiefly occupied with agriculture. The highest of the volcanic peaks rises to 12,000 feet above the sea. The eastern islands of this group are less productive and less advanced. Sumatra. Java.

35. *Borneo*, the most western and the largest of the northern group of islands which extends between the meridians of 110° and 150° E., as far as New Guinea or Papua, is but little known. The population is small, rude, and uncivilised; and the surface is rough and mountainous, and generally covered with forest except near the coast, to the alluvial lands on which settlers have been attracted from various surrounding countries. The highest mountains are supposed to rise to about 10,000 feet, but the ordinary elevations seem not to exceed 4000 or 5000 feet. Borneo.

36. Of *Celebes* less is known than of Borneo, which it resembles in condition and natural characteristics. The highest known peaks rise to 8000 feet, some of them being volcanic. Celebes.

37. *Papua* is perhaps somewhat smaller than Borneo. It extends almost to the same meridian as the eastern coast of Australia, from the north point of which it is separated by Torres Straits. Very little is known even of its coasts. The mountains in the interior are said to rise to 20,000 feet, having the appearance of being permanently covered with snow; the surface seems generally to be clothed with thick wood. The inhabitants are of the Negrito type, with curly or crisp and bushy hair; those of the west coast have come more into communication with the traders of other islands, and are fairly civilised. Eastward, many of the tribes are barbarous savages, with whom it is almost impossible for foreigners to hold intercourse. Papua.

38. The *Philippine* islands lie between the 15th and 20th degrees of N. lat., between Borneo and southern China. The highest land does not rise to a greater height than 6000 feet; the climate is well suited for agriculture, and the islands generally are fertile and fairly cultivated, though not coming up to the standard of Java either in wealth or population. The Spanish Government is established over the greater part of the group, though a considerable numerical proportion of the people is in some districts beyond their active control. Philippines.

39 *Formosa*, which is situated under the northern tropic, near the coast of China, is traversed by a high range of mountains, reaching nearly 13,000 feet in elevation. On its western side, which is occupied by an immigrant Chinese population, are open and well-cultivated plains; on the east it is mountainous, and occupied by independent indigenous tribes in a less advanced state. Formosa

40. The islands of *Japan* lie between the 30th and 45th parallels. The whole group is traversed by a line of volcanic mountains, some of which are in activity, the highest point being about 13,000 feet above the sea. The country is well watered, fertile, and well cultivated. The people are industrious and intelligent, and show much capacity for mechanical and ornamental art. They have recently attracted special attention from the sudden efforts made by their Government to accept and introduce Western civilisation. Japan.

41. Materials are wanting for anything like a connected sketch of the geological structure of the continent of Asia, and little more can be done than to indicate a few GEOLOGY.

facts which tend to throw light on the probable epochs at which the land has assumed its present configuration.

Tertiary deposits.

42. There is evidence of the very recent formation, speaking geologically, of the great plains of Northern India, of Mesopotamia, and of portions of Central Asia and Siberia. The existence of deposits containing large mammalian remains of the older Pliocene or Miocene divisions of the Tertiary period, has been ascertained at many places on the low lands of British India, in Burmah on the east, along the foot of the Himalaya, and near the Gulf of Cutch on the west, which indicates that very great changes of level and of conditions of surface have taken place in those localities since the later Tertiary epoch. The far wider spread of the older tertiaries proves that far greater alterations have occurred since the Eocene period. Nummulitic limestones are found from Burmah to Eastern Bengal; they are continuous along the flank of the table-land of Baluchistan, through Sindh to the Himalaya; they are frequent throughout Persia, Asia Minor, Syria, Egypt, and along the Caspian; they are found at great elevations in the Himalaya—in one locality at more than 16,000 feet above the sea; all this indicates that over a vast region, which is now dry land, often rising to very great altitudes, there existed a sea area at a period which, geologically speaking, appertains to the more recent epochs of the earth's history. Hence the present configuration of the land must be due to movements of a subsequent date; and it is thus shown that the vast elevation of the great Tibetan table-land is due to changes which are among the latest to which the earth's surface has been subjected. No doubt the Caspian and Aral seas formed part of the ancient ocean which once occupied a great part of what is now Western Asia.

Recent elevation of mountains and plains.

Himalaya.

43. The occurrence of a regular succession of the older fossiliferous deposits, from Upper Silurian upwards to the Triassic and Jurassic, and even to the Cretaceous formations, along the line lying to the north of the highest Himalayan ranges, gives ground for the supposition that an ancient sea-coast may have existed along this line; and that from a still earlier period there was dry land to the south, where the Himalaya now stands. Thus these mountains may have continued, as a chain of some importance, to occupy their present position from a period anterior to the Silurian epoch, while their existing very great elevation is probably due to the disturbances which have taken place since the middle of the Tertiary period.

Indian peninsula.

44. There is no sufficient evidence of the former extent or distribution of the land south of the Himalaya. But from the absence of marine fossiliferous deposits of the older epochs, it has been inferred that the greater part, at least, of the peninsula of India may have been an area of dry land from a very remote time up to the middle of the Tertiary period, during which the great basaltic formations of Central India are supposed to have been thrown up; a partial submergence then seems to have occurred, followed by a re-elevation, which gave the continent its present form. The fossil remains that have been found indicate the presence, in the Triassic or Permian age, of a great continental area, extending from Europe, and forming a connection across the Indian Ocean between South Africa and the peninsula of India. Grounds also exist for supposing that the Indian peninsula was formerly united by dry land with Australia, and that, when these conditions prevailed, the peninsula was separated by sea from the rest of Asia. Other evidence of this is to be found in the distribution of the races of men, and of plants and animals.

Siberia.

45. The occurrence of a large area of Silurian and other Palæozoic rocks in Northern Siberia, extending to the Altai mountains, with an apparent absence of the Mesozoic, has been explained as probably due to the existence of a marine area during the Palæozoic epoch, at the close of which it was replaced by an area of land; this was again submerged in the latest Tertiary period, during which a great part of the country was covered with the diluvial deposits, in which are found the remains of large mammalia.

China. Central Asia.

46. The presence of coal in many parts of China and Mongolia is a further indication of great former changes of condition of the surface in that part of the continent.

Himalayan glaciers.

47. Evidence exists of a former far greater extension of glaciers on the Himalaya, possibly at the period during which the great glacial phenomena of Europe occurred; but too little is known to enable us to affirm that this indicates any general period of cold that affected the northern hemisphere as far south as the Himalaya, though the facts are sufficiently striking to suggest such a conclusion. Another explanation of the decrease of Himalayan glaciers is that it was a consequence of the diminution of the fall of snow, consequent on the gradual change of climate which must have followed a gradual transformation of an ocean area into one of dry land. This last-named circumstance would also account for the great changes in the quantity of rain-fall, and in the flow of the rivers, of which there are many indications in Western India, in Persia, and the regions east of the Caspian.

Volcanoes.

48. A remarkable feature of Asia is the line of volcanic activity which extends along its eastern coast through Kamchatka, the Kurile and Japanese islands, Formosa, and the Philippines, to the Malay archipelago. Thence the line is prolonged to the west, through Java and Sumatra to the Bay of Bengal, where it ends about in lat. 20° N. on the coast of Aracan. To the east and south there also seems to be a connection with the volcanic regions of New Zealand and the islands of the Pacific, and possibly with that of the antarctic land. There is no authentic evidence of active volcanoes in the interior of the continent.

Dependence of present organic forms on past conditions.

49. Although these facts give an extremely incomplete view of the geological structure of Asia, they will afford some slight idea of the great changes that have taken place throughout all parts of the continent, and serve to convey a warning of the necessity for taking such changes into account, when attempts are made to understand the manner in which animals and plants are distributed on the earth's surface, and how their development may have taken place. The phenomena of living creatures as now observed are the results of various causes which have been in operation through a long period of time. Those causes which still continue to be in action may, in some respects, call for special attention, as determining the precise conditions under which organisations now have to exist, and as being those which now tend to destroy what has been, and to substitute something different in its place. But what remains necessarily depends on what preceded it, and the knowledge of the conditions and forms of life in the past is an essential element of the proper understanding of life as it now is.

CLIMATE

50. *Climate* is among the most important of the conditions affecting all forms of life. Under this general term is designated the complicated series of phenomena which arise in the air surrounding any locality, and in the watery vapour diffused through that air. These phenomena, which include the variations of temperature and of moisture, the winds, the rain, and the electrical condition of the air, depend essentially on the action of solar heat on the atmosphere and the materials of the terrestrial globe. The main conditions which determine the climate of any place, are position on the earth in respect to latitude, elevation above the sea level, and character of the surface in relation to its power of absorbing or radiating heat. Owing to the extreme mobility of the air, its temperature and the quantity of moisture it contains are further influenced in a very

important degree by the proximity of large areas of land and water and mountain ranges, and by the position of such areas or ranges in relation to the direction of the earth's motion on its axis. On no portion of the globe are the diversities of climate due to these causes more remarkable, or brought into more striking contrast, than in Asia.

51. Among the places on the globe where the temperature falls lowest are some in Northern Asia, and among those where it rises highest are some in Southern Asia. The mean temperature of the north coast of Eastern Siberia is but a few degrees above the zero of Fahrenheit; the lowest mean temperature anywhere observed is about 4° Fahr., at Melville Island, north of the American continent. The isothermals of mean annual temperature lie over Northern Asia on curves tolerably regular in their outline, having their western branches in a somewhat higher latitude than their eastern; a reduction of 1° of latitude corresponds approximately—and irrespective of modifications due to elevation—to a rise of ½° Fahr., as far say as lat. 30° N., where the mean temperature is about 75° Fahr. Further south the increase is slower, and the highest mean temperature anywhere attained in Southern Asia is not much above 82° Fahr.

Monthly variations

52. The variations of temperature are very great in Siberia, amounting near the coast to more than 100° Fahr., between the mean of the hottest and coldest months, and to still more between the extreme temperatures of those months. In Southern Asia, and particularly near the sea, the variation between the hottest and coldest monthly means is very much less, and under the equator it is reduced to about 5° In Siberia the difference between the means of the hottest and coldest months is hardly anywhere less than 60° Fahr. On the Sea of Aral it is 80° Fahr.; and at Astrakhan, on the Caspian, more than 50°. At Tiflis it is 45° In Northern China, at Peking, it is 55°, reduced to 30° at Canton, and to 20° at Manilla. In Northern India the greatest difference does not exceed 40°; and it falls off to about 15° at Calcutta, and to about 10° or 12° at Bombay and Madras. The temperatures at the head of the Persian Gulf approximate to those of Northern India, and those of Aden to Madras. At Singapore the range is less than 5°; and at Batavia in Java, and Galle in Ceylon, it is about the same. The extreme temperatures in Siberia may be considered to lie between 80° and 90° Fahr. for maxima, and between −40° and −70° Fahr. for minima. The extreme of heat near the Caspian and Aral seas rises to nearly 100° Fahr., while that of cold falls to −20° Fahr., or lower. Compared with these figures, we find in Southern Asia 110° or 112° Fahr. as a maximum hardly ever exceeded. The absolute minimum in Northern India, in lat. 30°, hardly goes below 32°; at Calcutta it is about 40°, though the thermometer seldom falls to 50° At Madras it rarely falls as low as 65°, or at Bombay below 60° At Singapore and Batavia the thermometer very rarely falls below 70°, or rises above 90°. At Aden the minimum is a few degrees below 70°, the maximum not much exceeding 90°.

Extreme temperatures

General characteristics.

53. These figures sufficiently indicate the main characteristics of the air temperatures of Asia. Throughout its northern portion the winter is long and of extreme severity; and even down to the circle of 35° N. lat., the minimum temperature is almost as low as zero of Fahrenheit. The summers are hot, though short in the northern latitudes, the maximum of summer heat being comparatively little less than that observed in the tropical countries further south. The moderating effect of the proximity of the ocean is felt in an important degree along the southern and eastern parts of Asia, where the land is broken up into islands or peninsulas. The great elevation above the sea level of the central part of Asia, and of the table-lands of Afghanistan and Persia, tends to exaggerate the winter cold; while the sterility of the surface, due to the small rain-fall over the same region, operates powerfully in the opposite direction in increasing the summer heat. In the summer a great accumulation of solar heat takes place on the dry surface soil, from which it cannot be released upwards by evaporation, as might be the case were the soil moist or covered with vegetation, nor can it be readily conveyed away downwards as happens on the ocean. In the winter similar consequences ensue, in a negative direction, from the prolonged loss of heat by radiation in the long and clear nights—an effect which is intensified wherever the surface is covered with snow, or the air little charged with vapour In illustration of the very slow diffusion of heat in the solid crust of the earth, and as affording a further indication of the climate of Northern Asia, reference may here be made to the frozen soil of Siberia, in the vicinity of Yakutsk. In this region the earth is frozen permanently to a depth of more than 380 feet, at which the temperature is still 5° or 6° Fahr. below the freezing point of water, the summer heat merely thawing the surface to a depth of about 3 feet. At a depth of 50 feet the temperature is about 15° Fahr. below the freezing point. Under such conditions of the soil, the land, nevertheless, produces crops of wheat and other grain from fifteen to forty fold.

High summer temperatures.

54. The very high summer temperatures of the area north of the tropic of Cancer are sufficiently accounted for, when compared to those observed south of the tropic, by the increased length of the day in the higher latitude, which more than compensates for the loss of heat due to the smaller midday altitude of the sun. The difference between the heating power of the sun's rays at noon on the 21st June, in latitude 20° and in latitude 45°, is only about 2 per cent; while the accumulated heat received during the day, which is lengthened to 15½ hours in the higher latitude, is greater by about 11 per cent. than in the lower latitude, where the day consists only of 13¼ hours.

Modifying causes.

55. Although the foregoing account of the temperatures of Asia supplies the main outline of the observed phenomena, a very important modifying cause, of which more will be said hereafter, comes into operation over the whole of the tropical region, namely, the periodical summer rains. These tend very greatly to arrest the increase of the summer heat over the area where they prevail, and otherwise give it altogether peculiar characteristics.

Periodical variation of air pressure.

56. The great summer heat, by expanding the air upwards, disturbs the level of the planes of equal pressure, and causes an outflow of the upper strata from the heated area. The winter cold produces an effect of just an opposite nature, and causes an accumulation of air over the cold area. The diminution of barometric pressure which takes place all over Asia during the summer months, and the increase in the winter, are hence, no doubt, the results of the alternate heating and cooling of the air over the continent.

Periodical winds.

57 The necessary and immediate results of such periodical changes of pressure are winds, which, speaking generally, blow from the area of greatest to that of least pressure,—subject, however, to certain modifications of direction, arising from the absolute motion of the whole body of the air due to the revolution of the earth on its axis from west to east. At the equator, where the velocity of revolution is about 1037 miles per hour, what is called calm air is in absolute motion from west to east with that velocity. If such air were impelled by any disturbance of pressure, from the equator northward, it would advance gradually to places having a less and less velocity of rotation, so that at lat. 15° N. the earth would be only moving with a

Effect of earth's revolution.

velocity of about 1002 miles per hour, while the air arriving from the equator (supposing it not to have been affected by friction) would be moving from west to east 35 miles per hour faster than the surface, and would therefore be felt as a wind having that velocity from the *west*. In fact, however, the motion from the south would be combined with that from the west, and the air would blow as a south-west wind; while the friction against the earth's surface would gradually check the excess of velocity toward the east, and no such great westerly velocity as that named would be developed. In a corresponding manner, air impelled from places situated on a higher latitude towards those on a lower, will be felt as wind having an easterly component. The south-westerly winds, which prevail north of the equator during the hot half of the year, to which navigators have given the name of the S.W. monsoon (the latter word being a corruption of the Indian name for *season*), arise, in the manner just explained, from the great diminution of atmospheric pressure over Asia, which begins to be strongly marked with the great rise of temperature in April and May, and the simultaneous relative higher pressure over the equator and the regions south of it. This diminution of pressure, which continues as the heat increases till it reaches its maximum in July soon after the solstice, is followed by the corresponding development of the S.W. monsoon; and as the barometric pressure is gradually restored, and becomes equalised within the tropics soon after the equinox in October, with the general fall of temperature north of the equator, the south-west winds fall off, and are succeeded by a N.E. monsoon, which is developed during the winter months by the relative greater atmospheric pressure which then occurs over Asia, as compared to the equatorial region.

Monsoons.

Direction, how modified.

58. Although the succession of the periodical winds follows the progress of the seasons as just described, the changes in the wind's direction everywhere take place under the operation of special local influences which often disguise the more general law, and make it difficult to trace. Thus the S.W. monsoon begins in the Arabian Sea with west and north-westerly winds, which draw round as the year advances to south-west, and fall back again in the autumn by north-west to north. In the Bay of Bengal the strength of the S.W. monsoon is rather from the south and south-east, being succeeded by north-east winds after October, which give place to northerly and north-westerly winds as the year advances. Among the islands of the Malay Archipelago the force of the monsoons is much interrupted, and the position of this region on the equator otherwise modifies the directions of the prevailing winds. The southerly summer winds of the Asiatic seas between the equator and the tropic do not extend to the coasts of Java, and the south-easterly trade winds are there developed in the usual manner. The China Sea is fully exposed to both monsoons, the normal directions of which nearly coincide with the centre of the channel between the continent of Asia and the eastern islands.

Do not extend inland.

59. The south-west monsoon does not generally extend, in its character of a south-west wind, over the land. The current of air flowing in from over the sea is gradually diverted towards the area of least pressure, and at the same time is dissipated and loses much of its original force. The winds which pass northward over India blow as south-easterly and easterly winds over the north-eastern part of the Gangetic plain, and as south winds up the Indus. They seem almost entirely to have exhausted their northward velocity by the time they have reached the northern extremity of the great Indian plain; they are not felt on the table-lands of Afghanistan, and hardly penetrate into the ranges of the Himalaya, by which mountains, and those which branch off from them into the Malay peninsula, they are prevented from continuing their progress in the direction originally imparted to them.

Cyclones.

60. Among the more remarkable phenomena of the hotter seas of Asia must be noticed the revolving storms or cyclones, which are of frequent occurrence in the hot months in the Indian Ocean and China Sea, in which last they are known under the name of typhoon. The cyclones of the Bay of Bengal appear to originate over the Andaman and Nicobar islands, and are commonly propagated in a north-westward direction, striking the east coast of the Indian peninsula at various points, and then often advancing with an easterly tendency over the land, and passing with extreme violence across the delta of the Ganges. They occur in all the hot months, from June to October, and more rarely in November, and appear to be originated by adverse currents from the north meeting those of the S.W. monsoon. The cyclones of the China Sea also occur in the hot months of the year, but they advance from N.E. to S.W., though occasionally from E. to W.; they originate near the island of Formosa, and extend to about the 10th degree of N. lat. They are thus developed in nearly the same latitudes and in the same months as those of the Indian Sea, though their progress is in a different direction. In both cases, however, the storms appear to advance towards the area of greatest heat. In these storms the wind invariably circulates from N. by W. through S. to E.

Bay of Bengal.

China.

Southern Indian Ocean.

61. In the cyclones observed in the Southern Indian Ocean off the coast of Madagascar the wind circulates in the opposite direction. These storms advance from N.E. to S.W., with a tendency to turn off to the S.E. as they die out. They occur between the months of December and April, and between the 10th degree of S. lat. and the southern tropic.

Their causes.

62. In all these cases the cyclones occur during the hot months of the year, when strong winds are developed by the proximity of large heated areas of land and relatively cool areas of sea, and when the air, being highly charged with vapour, is liable to great disturbances of temperature on any considerable condensation being set up. Moreover, they most frequently happen at the times when the direction of the dominant winds is changing, and when important variations of atmospheric pressure are certainly taking place. Actual barometric observations have not yet been obtained in sufficient number or continuity to establish the precise conditions under which these storms arise, but there is no reason to doubt the correctness of the general views held regarding them, or that with the progress of knowledge much may be done to enable mariners to avoid their worst consequences.

Rains of S.W. monsoon.

63. The heated body of air carried from the Indian Ocean over Southern Asia by the S.W. monsoon comes up highly charged with watery vapour, and hence in a condition to release a large body of water as rain upon the land, whenever it is brought into circumstances which reduce its temperature in a notable degree. Such a reduction of temperature is brought about along the greater part of the coasts of India and of the Burmo-Siamese peninsula by the interruption of the progress of the wind current by continuous ranges of mountains, which force the mass of air to rise over them, whereby the air being rarefied, its specific capacity for heat is increased and its temperature falls, with a corresponding condensation of the vapour originally held in suspension.

Their causes.

General character.

64. This explanation of the principal efficient cause of the summer rains of South Asia is immediately based on an analysis of the complicated phenomena actually observed, and it serves to account for many apparent anomalies. The heaviest falls of rain occur along lines of mountain of some extent directly facing the vapour-bearing winds, as on the Western Ghats of India and the west coast of the

Malay peninsula. The same results are found along the mountains at a distance from the sea, the heaviest rainfall known to occur anywhere in the world (not less than 600 inches in the year) being recorded on the Khasiya range about 100 miles north-east of Calcutta, which presents an abrupt front to the progress of the moist winds flowing up from the Bay of Bengal. The cessation of the rains on the southern border of Baluchistan, west of Kurrachee, obviously arises from the projection of the south-east coast of Arabia, which limits the breadth of the S.W. monsoon air current and the length of the coast line directly exposed to it. The very small and irregular rainfall in Sindh and along the Indus is to be accounted for by the want of any obstacle in the path of the vapour-bearing winds, which, therefore, carry the uncondensed rain up to the Punjab, where it falls on the outer ranges of the western Himalaya and of Afghanistan.

Land and sea breezes. 65. Somewhat similar results, though on a smaller scale, attend the operation of the well-known land and sea breezes, which are universally prevalent in hot countries bordering on the sea. The relative greater heating of the land than of the sea during the day disturbs the planes of atmospheric equilibrium, and a dispersion of air in the higher regions from over the land leads to a diminution of pressure there and an increase over the sea. This causes the sea breeze, which is an inflow of moist air over the land from below; and where, as is frequently the case, this breeze is forced, as it advances, to rise considerably above the sea level, condensation takes place on the mountain slopes either in clouds or rain. The constant precipitation of rain on tropical coasts is mainly due to this action.

Diurnal mountain winds. 66. An analogous, though less well understood, system of alternating winds is almost invariably set up over mountains rising abruptly from plains, currents blowing from the higher ground to the lower during the night, and from the lower to the higher during the day. Such winds are often combined with the land and sea breezes, which they tend to exaggerate. The diurnal mountain winds are very strongly marked on the Himalaya, where they probably are the most active agents in determining the precipitation of rain along the chain—the monsoon currents, as was before stated, not penetrating among the mountains. The formation of dense banks of cloud in the afternoon, when the up wind is strongest, along the southern face of the snowy ranges of the Himalaya, is a regular daily phenomenon during the hotter months of the year, and heavy rain, accompanied by electrical discharges, is the frequent result of such condensation.

Rainfall. 67. Too little is known of the greater part of Asia to admit of any more being said with reference to this part of the subject, than to mention a few facts bearing on the rainfall. At Tiflis the yearly fall is 22 inches; on the Caspian about 7 or 8 inches; on the Sea of Aral 5 or 6 inches. In South-western Siberia it is 12 or 14 inches, diminishing as we proceed eastward to 6 or 7 inches at Barnaul, and to 5 or 6 inches at Urga in Northern Mongolia. At Nertschinsk in Eastern Siberia it is about 15 to 20 inches. In China we find about 23 inches to be the fall at Peking; while at Canton, which lies nearly on the northern tropic and the region of the S.W. monsoon is entered, the quantity is increased to 78 inches. At Batavia in Java the fall is about 78 inches; at Singapore it is nearly 100 inches. The quantity increases considerably on that part of the coast of the Malay peninsula which is not sheltered from the south-west by Sumatra. On the Tenasserim and Burmese coast falls of more than 200 inches are registered, and the quantity is here nowhere less than 75 or 80 inches, which is about the average of the eastern part of the delta of the Ganges, Calcutta standing at about 64 inches. On the hills that flank Bengal on the east the fall is very great. On the Khasiya hills, at an elevation of about 4500 feet, the average of 10 years is more than 550 inches. As much as 150 inches has been measured in one month, and 610 inches in one year. On the west coast of the Indian peninsula the fall at the sea level varies from about 75 to 100 inches, and at certain elevations on the mountains more than 250 inches is commonly registered, with intermediate quantities at intervening localities. On the east coast the fall is far less, nowhere rising to 50 inches, and towards the southern apex of the peninsula being reduced to 25 or 30 inches. Ceylon shows from 60 to 80 inches. As we recede from the coast the fall diminishes, till it is reduced to about 25 or 30 inches at the head of the Gangetic plain. The tract along the Indus to within 60 or 80 miles of the Himalaya is almost rainless, 6 or 8 inches being the fall in the southern portion of the Punjab. On the outer ranges of the Himalaya the yearly fall amounts to about 200 inches on the east in Sikim, and gradually diminishes on the west, where north of the Punjab it is about 70 or 80 inches. In the interior of the chain the rain is far less, and the quantity of precipitation is so small in Tibet that it can be hardly measured. It is to the greatly reduced fall of snow on the northern faces of the highest ranges of the Himalaya that is to be attributed the higher level of the snow-line, a phenomenon which was long a cause of discussion.

Seasons of rain. 68. In Afghanistan, Persia, Asia Minor, and Syria, winter and spring appear to be the chief seasons of condensation. In other parts of Asia the principal part of the rain falls between May and September, that is, in the hottest half of the year. In the islands under the equator the heaviest fall is between October and February.

BIOLOGY. 69. Such are the climatal conditions of the principal regions of Asia, under which the plants and animals that inhabit them are at present distributed. In attempting to appreciate and to explain the very complicated facts of distribution it is essential to bear in mind that what we find at the present time is, as was before observed, the result of causes that have been in operation from periods long antecedent to that in which the earth has taken its existing form, and acquired its existing conditions of temperature, climate, and arrangement of land and sea areas. Our knowledge of the manner in which the successive changes which have affected the earth's surface took place is, however, still so imperfect, that it is often not possible to state with certainty how the facts of distribution have occurred, and much is yet open to conjecture. But there is, notwithstanding, an overwhelming force of argument to establish the conclusion, that the diffusion of the forms of animal and vegetable life has gone on for a vast length of time by natural descent, and subject to the action of tendencies to variation; the general result being that the forms which first existed have been suppressed, and others introduced in their places. This modification of form in *time* is seen to have been commonly accompanied by a corresponding movement or diffusion in *place*, governed no doubt primarily by the variations of temperature and climate and conditions of surface which have accompanied the movements of the solid crust of the earth, or may have been due to cyclical change. The conformity of the facts of the geographical distribution of life with this conception is no longer seriously questioned. The mutual relations among the several branches of animal and vegetable life, and the marked effects produced on all organised creatures by conditions of climate, are apparent. The abundance of certain forms of animals and plants in certain areas, and their gradual diminution in number beyond such areas until they disappear altogether, is well known; as also the ordinary similarity of the general assemblages of living creatures in countries not far distant from one

Distribution of life. Causes of change.

another, and having similar conditions of climate. In proportion as the distance between two areas increases, and their mutual accessibility diminishes, and their conditions of climate differ, the likeness of the forms of life within them becomes less, until the connection may be reduced to what is due to common descent from extremely remote ancestors.

Forms of life in Asia. 70. Turning to the continent of Asia, such broadly characterised similarities and differences will be seen to be well marked. The general assemblage of animals and plants found over Northern Asia resembles greatly that found in the parts of Europe which are adjacent, and which have a similar climate. Siberia. Siberia, north of the 50th parallel, has a climate not much differing from the similarly situated portion of Europe, though the winters are more severe and the summers hotter. The rainfall, though moderate, is still sufficient to maintain the supply of water in the great rivers that traverse the country to the Arctic Sea, and to support an abundant vegetation. A similar affinity exists between the life of the southern parts of Europe and that in the zone of Asia extending from the Mediterranean across to the Himalaya and Northern China. Persian plateau. Himalaya. This belt, which embraces Asia Minor, Northern Persia, Afghanistan, and the southern slopes of the Himalaya, from its elevation has a temperate climate, and throughout it the rainfall is sufficient to maintain a vigorous vegetation, while the summers, though hot, and the winters, though severe, are not extreme. The plants and animals along it are found to have a marked similarity of character to those of South Europe, with which region the zone is virtually continuous

Arabia. Sindh. 71. The extremely dry and hot tracts which constitute an almost unbroken desert from Arabia, through South Persia and Baluchistan, to Sindh, are characterised by considerable uniformity in the types of life, which closely approach to those of the neighbouring hot and dry regions of Africa. India. The region of the heavy periodical summer rains and high temperature, which comprises India, the Indo-Chinese peninsula, and Southern China, as well as the western part of the Malay Archipelago, is also marked by much similarity in the plants and animals throughout its extent. Central Asia. The area between the southern border of Siberia and the margin of the temperate alpine zone of the Himalaya and North China, comprising what are commonly called Central Asia, Turkistan, Mongolia, and Western Manchuria, is an almost rainless region, having winters of extreme severity and summers of intense heat. Its animals and plants have a special character suited to the peculiar climatal conditions, more closely allied to those of the adjacent northern Siberian tract than of the other bordering regions. The south-eastern parts of the Malay islands have much in common with the Australian continent, Malay islands. to which they adjoin, though their affinities are chiefly Indian. North China and Japan also have many forms of life in common. Much still remains to be done in the exploration of China and Eastern Asia; but it is China. known that many of the special forms of this region extend to the Himalaya, while others clearly indicate a connection with North America.

72. The foregoing brief review of the principal territorial divisions according to which the forms of life are distributed in Asia, indicates how close is the dependence of this distribution on climatal conditions, and this will be made more apparent by a somewhat fuller account of the main features of the flora and fauna.

BOTANY. Flora of Siberia. 73. The flora of the whole of Northern Asia is in essentials the same as that of Northern Europe, the differences being due rather to variations of species than of genera. The absence of the oak and of all heaths east of the Ural may be noticed. Pines, larch, birch, are the principal trees on the mountains; willows, alders, and poplars on the lower ground. The northern limit of the pine in Siberia is about lat. 70°.

74. Along the warm temperate zone, from the Mediterranean to the Himalaya, extends a flora essentially European in character. Warm temperate zone. Many European *species* reach the central Himalaya, though few are known in its eastern parts. The *genera* common to the Himalaya and Europe are much more abundant, and extend throughout the chain, and to all elevations. There is also a corresponding diffusion of Japanese and Chinese forms along this zone, these being most numerous in the eastern Himalaya, and less frequent in the west.

75. The truly tropical flora of the hotter and wetter regions of Eastern India is continuous with that of the Malayan peninsula and islands, Eastern India and Malay islands. and extends along the lower ranges of the Himalaya, gradually becoming less marked, and rising to lower elevations as we go westward, where the rainfall diminishes and the winter cold increases.

76. The vegetation of the higher and therefore cooler Himalaya. and less rainy ranges of the Himalaya has greater uniformity of character along the whole chain, and a closer general approach to European forms is maintained; an increased number of species is actually identical, among these being found, at the greatest elevations, many alpine plants believed to be identical with species of the north Arctic regions. Tibet. On reaching the Tibetan plateau, with the increased dryness the flora assumes many features of the Siberian type. Many true Siberian species are found, and more Siberian genera. Some of the Siberian forms, thus brought into proximity with the Indian flora, extend to the rainy parts of the mountains, and even to the plains of upper India. Assemblages of marine plants form another remarkable feature of Tibet, these being frequently met with growing at elevations of 14,000 to 15,000 feet above the sea, more especially in the vicinity of the many salt lakes of those regions.

77. The vegetation of the hot and dry region of the Hot and desert region. south-west of the continent consists largely of plants which are diffused over Africa, Baluchistan, and Sindh; many of these extend into the hotter parts of India, and not a few common Egyptian plants are to be met with in the Indian peninsula.

78. The whole number of species of plants indigenous in Indian flora. the region of south-eastern Asia, which includes India and the Malayan peninsula and islands, from about the 65th to the 105th meridian, is estimated by Dr Hooker at from 12,000 to 15,000. The principal orders, arranged according to their numerical importance, are as follows:—*Leguminosæ, Rubiaceæ, Orchideæ, Compositæ, Gramineæ, Euphorbiaceæ, Acanthaceæ, Cyperaceæ*, and *Labiatæ*. But within this region there is a very great variation between the vegetation of the more humid and the more arid regions, while the characteristics of the flora on the higher mountain ranges differ wholly from those of the plains. In short, we have a somewhat heterogeneous assemblage of tropical, temperate, and alpine plants, as has been already briefly indicated, of which, however, the tropical are so far dominant as to give their character to the flora viewed as a whole. The Indian flora contains a more general and complete illustration of almost all the chief natural families of all parts of the world than any other country. *Compositæ* are comparatively rare; so also *Gramineæ* and *Cyperaceæ* are in some places deficient, and *Labiatæ, Leguminosæ*, and ferns in others. *Euphorbiaceæ*, and *Scrophulariaceæ*, and *Orchideæ* are universally present, the last in specially large proportions.

79. The perennially humid regions of the Malayan peninsula Malayan peninsula. and western portion of the archipelago are everywhere covered with dense forest, rendered difficult to traverse by the thorny cane, a palm of the genus Calamus, which has

its greatest development in this part of Asia. The chief trees belong to the orders of *Terebinthaceæ*, *Sapindaceæ*, *Meliaceæ*, *Clusiaceæ*, *Dipterocarpeæ*, *Ternstrœmiaceæ*, *Leguminosæ*, laurels, oaks, and figs, with *Dilleniaceæ*, *Sapotaceæ*, and nutmegs. Bamboos and palms, with *Pandanus* and *Dracæna*, are also abundant. A similar forest flora extends along the mountains of eastern India to the Himalaya, where it ascends to elevations varying from 6000 to 7000 feet on the east to 3000 or 4000 feet on the west.

Eastern India.

North India.

80. The arboreous forms which least require the humid and equable heat of the more truly tropical and equatorial climates, and are best able to resist the high temperatures and excessive drought of the northern Indian hot months from April to June, are certain *Leguminosæ*, *Bauhinia*, *Acacia*, *Butea*, and *Dalbergia*, *Bombax*, *Shorea*, *Nauclea*, *Lagerstrœmia*, and *Bignonia*, a few bamboos and palms, with others which extend far beyond the tropic, and give a tropical aspect to the forest to the extreme northern border of the Indian plain.

Herbaceous forms.

81. Of the herbaceous vegetation of the more rainy regions may be noted the *Orchideæ*, *Orontiaceæ*, *Scitamineæ*, with ferns and other Cryptogams, besides *Gramineæ* and *Cyperaceæ*. Among these some forms, as among the trees, extend much beyond the tropic and ascend into the temperate zones on the mountains, of which may be mentioned *Begonia*, *Osbeckia*, various *Cyrtandraceæ*, *Scitamineæ*, and a few epiphytical orchids.

Special features of flora.

82. Of the orders most largely developed in South India, and more sparingly elsewhere, may be named *Aurantiaceæ*, *Dipterocarpeæ*, *Balsamineæ*, *Ebenaceæ*, *Jasmineæ*, and *Cyrtandraceæ;* but of these few contain as many as 100 peculiar Indian species. *Nepenthes* may be mentioned as a genus specially developed in the Malayan area, and extending from New Caledonia to Madagascar; it is found as far north as the Khasiya hills, and in Ceylon, but does not appear on the Himalaya or in the peninsula of India. The *Balsamineæ* may be named as being rare in the eastern region and very abundant in the peninsula. A distinct connection between the flora of the peninsula and Ceylon, and that of eastern tropical Africa is observable not only in the great similarity of many of the more truly tropical forms, and the identity of families and genera found in both regions, but in a more remarkable manner in the likeness of the mountain flora of this part of Africa to that of the peninsula, in which several species occur believed to be identical with Abyssinian forms. This connection is further established by the absence from both areas of oaks, conifers, and cycads, which, as regards the two first families, is a remarkable feature of the flora of the peninsula and Ceylon, as the mountains rise to elevations in which both of them are abundant to the north and east. With these facts it has to be noticed that many of the principal forms of the eastern flora are absent or comparatively rare in the peninsula and Ceylon.

Physiognomy of flora—Eastern India.

83. The general physiognomy of the Indian flora is mainly determined by the conditions of humidity of climate. The impenetrable shady forests of the Malay peninsula and Eastern Bengal, of the west coast of the Indian peninsula, and of Ceylon, offer a strong contrast with the more loosely-timbered districts of the drier regions of Central India and the North-western Himalaya. There are no plains covered with forest as in tropical America, the low lands of India being either highly cultivated and adorned with planted wood, or, where cut off from rain, nearly complete desert.

Himalaya.

84. The higher mountains rise abruptly from the plains; on their slopes, clothed below almost exclusively with the more tropical forms, a vegetation of a warm temperate character, chiefly evergreen, soon begins to prevail, comprising *Magnoliaceæ*, *Ternstrœmiaceæ*, sub-tropical *Rosaceæ*, rhododendron, oak, *Ilex*, *Symplocos*, *Laurineæ*, *Pinus longifolia*, with mountain forms of truly tropical orders, palms, *Pandanus*, *Musa*, *Vitis*, *Vernonia*, and many others. On the east the vegetation of the Himalaya is most abundant and varied. The forest extends, with great luxuriance, to an elevation of 12,000 feet, above which the sub-alpine region may be said to begin, in which rhododendron scrub often covers the ground up to 13,000 or 14,000 feet. Only one pine is found below 8000 feet, above which several other *Coniferæ* occur. Plantains, tree-ferns, bamboos, several *Calami*, and other palms, and *Pandanus*, are abundant at the lower levels. Between 4000 and 8000 feet epiphytal orchids are very frequent, and reach even to 10,000 feet. Vegetation ascends on the drier and less snowy mountain slopes of Tibet to above 18,000 feet. On the west, with the drier climate, the forest is less luxuriant and dense, and the hill sides and the valleys better cultivated. The warm mountain slopes are covered with *Pinus longifolia*, or with oaks and rhododendron, and the forest is not commonly dense below 8000 feet, excepting in some of the more secluded valleys at a low elevation. From 8000 to 12,000 feet, a thick forest of deciduous trees is almost universal, above which a sub-alpine region is reached, and vegetation as on the east continues up to 18,000 feet or more. The more tropical forms of the east, such as the tree-ferns, do not reach west of Nepaul. The cedar or Deodar is hardly indigenous east of the sources of the Ganges, and at about the same point the forms of the west begin to be more abundant, increasing in number as we advance towards Afghanistan.

Eastern.

Western.

Cultivated plants.

85. The cultivated plants of the Indian region include wheat, barley, rice, and maize; various millets, *Sorghum*, *Penicillaria*, *Panicum*, and *Eleusine;* many pulses, peas, and beans; mustard and rape; ginger and turmeric; pepper and capsicum; several *Cucurbitaceæ;* tobacco, *Sesamum*, poppy, *Crotolaria*, and *Cannabis;* cotton, indigo, and sugar; coffee and tea; oranges, lemons of many sorts; pomegranate, mango, figs, peaches, vines, and plantains. The more common palms are *Cocos*, *Phœnix*, and *Borassus*, supplying cocoa-nut and toddy. Indian agriculture combines the harvests of the tropical and temperate zones. North of the tropic the winter cold is sufficient to admit of the cultivation of almost all the cereals and vegetables of Europe, wheat being sown in November and reaped early in April. In this same region the summer heat and rain provide a thoroughly tropical climate, in which rice and other tropical cereals are freely raised, being as a rule sown early in July, and reaped in September or October. In southern India, and the other parts of Asia and of the islands having a similar climate, the difference of the winter and summer half years is not sufficient to admit of the proper cultivation of wheat or barley. The other cereals may be seen occasionally, where artificial irrigation is practised, in all stages of progress at all seasons of the year, though the operations of agriculture are, as a general rule, limited to the rainy months, when alone is the requisite supply of water commonly forthcoming.

Timber trees.

86. The trees of India producing economically useful timber are comparatively few, owing to the want of durability of the wood, in the extremely hot and moist climate. The teak, *Tectona grandis*, supplies the finest timber. It is found in greatest perfection in the forests of the west coasts of Burmah and the Indian peninsula, where the rainfall is heaviest, growing to a height of 100 or 150 feet, mixed with other trees and bamboos. The sál, *Shorea robusta*, a very durable wood, is most abundant along the skirts of the Himalaya from Assam to the Punjab, and is found in Central India, to which the teak also extends. The sal grows to a large size, and is more gregarious than the teak. Of other useful woods found in the plains may

be named the babool, *Acacia;* toon, *Cedrela;* and sissoo, *Dalbergia*. The only timber in ordinary use obtained from the Himalaya proper is the Deodar, *Cedrus*, not distinct from the cedar of Lebanon. Besides these are the sandal-wood, *Santalum*, of Southern India, and many sorts of bamboo found in all parts of the country. The chinchona has recently been introduced with complete success; and the mahogany of America reaches a large size, and gives promise of being grown for use as timber.

Flora of desert region.

87. The flora of the rainless region of South-western Asia is continuous with the desert flora of Northern and Eastern Africa, and extends from the coast of Senegal to the meridian of 75° E., or from the great African desert to the border of the rainless tract along the Indus and the southern parts of the Punjab. It includes the peninsula of Arabia, the shores of the Persian Gulf, South Persia, and Afghanistan, and Baluchistan. On the west its limit is in the Cape de Verde Islands, and it is partially represented in Abyssinia.

Special features.

88. The more common plants in the most characteristic part of this region in Southern Arabia are *Capparideæ*, *Euphorbiaceæ*, and a few *Leguminosæ*, a *Reseda* and *Dipterygium;* palms, *Polygonaceæ*, ferns, and other cryptogams, are rare. The number of families relative to the area is very small, and the number of genera and species equally restricted, in very many cases a single species being the only representative of an order. The aspect of the vegetation is very peculiar, and is commonly determined by the predominance of some four or five species, the rest being either local or sparingly scattered over the area. The absence of the ordinary bright green colours of vegetation is another peculiarity of this flora, almost all the plants having glaucous or whitened stems. Foliage is reduced to a minimum, the moisture of the plant being stored up in massive or fleshy stems against the long-continued drought. Aridity has favoured the production of spines as a defence from external attack, sharp thorns are frequent, and asperities of various sorts predominate. Many species produce gums and resins, their stems being encrusted with the exudations, and pungency and aromatic odour is an almost universal quality of the plants of desert regions.

Hot region of Persian plateau.

89. The cultivated plants of Arabia are much the same as those of Northern India—wheat, barley, and the common *Sorghum*, with dates and lemons, cotton and indigo. To these must be added coffee, which is restricted to the slopes of the western hills. Among the more mountainous regions of the south-western part of Arabia, known as Arabia Felix, the summits of which rise to 6000 or 7000 feet, the rainfall is sufficient to develop a more luxuriant vegetation, and the valleys have a flora like that of similarly situated parts of southern Persia, and the less elevated parts of Afghanistan and Baluchistan, partaking of the characters of that of the hotter Mediterranean region. In these countries aromatic shrubs are abundant. Trees are rare, and almost restricted to *Pistacia*, *Celtis*, and *Dodonæa*, with poplars, and the date palm. Prickly forms of *Statice* and *Astragalus* cover the dry hills. In the spring there is an abundant herbaceous vegetation, including many bulbous plants, with genera, if not species, identical with those of the Syrian region, some of which extend to the Himalaya.

North Afghanistan

90. The flora of the northern part of Afghanistan approximates to that of the contiguous western Himalaya. *Quercus Ilex*, the evergreen oak of Southern Europe, is found in forests as far east as the Sutlej, accompanied with other European forms. In the higher parts of Afghanistan and Persia *Boragineæ* and thistles abound; gigantic *Umbelliferæ*, such as *Ferula*, *Galbanum*, *Dorema*, *Bubon*, *Peucedanum*, *Prangos*, and others, also characterise the same districts, and some of them extend into Tibet.

Persia and Asia Minor.

91. The flora of Asia Minor and Northern Persia differs but little from that of the southern parts of Europe. The mountains are clothed, where the fall of rain is abundant, with forests of *Quercus*, *Fagus*, *Ulmus*, *Acer*, *Carpinus*, and *Corylus*, and various *Coniferæ*. Of these the only genus that is not found on the Himalaya is *Fagus*. Fruit trees of the plum tribe abound. The cultivated plants are those of Southern Europe.

Malayan islands.

92. The vegetation of the Malayan Islands is for the most part that of the wetter and hotter region of India; but the greater uniformity of the temperature and humidity leads to the predominance of certain tropical forms not so conspicuous in India, while the proximity of the Australian continent has permitted the partial diffusion of Australian types which are not seen in India. The liquidambar and nutmeg may be noticed among the former; the first is one of the most conspicuous trees in Java, on the mountains of the eastern part of which the casuarina, one of the characteristic forms of Australia, is also abundant. Rhododendrons occur in Borneo and Sumatra, descending to the level of the sea. On the mountains of Java there appears to be no truly alpine flora; *Saxifraga* is not found. In Borneo some of the temperate forms of Australia appear on the higher mountains. On the other islands similar characteristics are to be observed, Australian genera extending to the Philippines, and even to Southern China.

China.

93. The analysis of the Hong Kong flora by Mr Bentham indicates that about three-fifths of the species are common to the Indian region, and nearly all the remainder are either Chinese or local forms. The number of specie common to Southern China, Japan, and Northern Asia is small. The cultivated plants of China are, with a few exceptions, the same as those of India. South China, therefore, seems, botanically, hardly distinct from the great Indian region, into which many Chinese forms penetrate, as before noticed. The flora of North China, which is akin to that of Japan, shows manifest relation to that of the neighbouring American continent, from which many temperate forms extend, reaching to the Himalaya, almost as far as Kashmir. Very little is known of the plants of the interior of Northern China, but it seems probable that a complete botanical connection is established between it and the temperate region of the Himalaya.

Central Asia.

94. The vegetation of the dry region of Central Asia is remarkable for the great relative number of *Chenopodiaceæ*, *Salicornia* and other salt plants being common; *Polygonaceæ* also are abundant; leafless forms being of frequent occurrence, which gives the vegetation a very remarkable aspect. Peculiar forms of *Leguminosæ* also prevail, and these, with many of the other plants of the southern and drier regions of Siberia, or of the colder regions of the desert tracts of Persia and Afghanistan, extend into Tibet, where the extreme drought and the hot (nearly vertical) sun combine to produce a summer climate not greatly differing from that of the plains of Central Asia.

ZOOLOGY.

95. The zoological provinces of Asia correspond very closely with the botanical. The northern portion of Asia, as far south as the Himalaya, is not zoologically distinct from Europe, and these two areas, with the strip of Africa north of the Atlas, constitute the Palæarctic region of Dr Sclater, whose zoological primary divisions of the earth have met with the general approval of naturalists. The south-eastern portion of Asia, with the adjacent islands of Sumatra, Java, Borneo, and the Philippines, form his Indian region. The extreme south-west part of the continent constitutes a separate zoological district, comprising Arabia, Palestine, and Southern Persia, and reaching, like the hot desert botanical tract, to Baluchistan and Sindh, it belongs to what Dr Sclater calls the Ethiopian region, which extends over Africa, south of the Atlas. The Celebes,

Papua, and the other islands east of Java beyond Wallace's line (see par. 6), fall within the Australian region.

A few words may be said about the characteristic animals of each of these divisions.

Palæarctic region. Mammals.

96. Nearly all the mammals of Europe also occur in Northern Asia, where, however, the Palæarctic fauna is enriched by numerous additional species. The characteristic groups belong mostly to forms which are restricted to cold and temperate regions. Consequently the Quadrumana or monkeys, are nearly unrepresented, a single species occurring in Japan, and one or two others in Northern China and Tibet. Insectivorous bats are numerous, but the frugivorous division of this order is only represented by a single species in Japan. Carnivora are also numerous, particularly the frequenters of cold climates, such as bears, weasels, wolves, and foxes. Of the Insectivora numerous forms of moles, shrews, and hedgehogs prevail. The Rodents are also well represented by various squirrels, mice, and hares. Characteristic forms of this order in Northern Asia are the marmots (*Arctomys*) and the pikas, or tailless hares (*Lagomys*). The great order of Ungulata is represented by various forms of sheep, as many as ten or twelve wild species of *Ovis* being met with in the mountain chains of Asia; and more sparingly by several peculiar forms of antelope, such as the saiga (*Saiga tartarica*), and the *Gazella gutturosa*, or yellow sheep. Coming to the deer, we also meet with characteristic forms in Northern Asia, especially those belonging to the typical genus *Cervus*. The musk deer (*Moschus*) is also quite restricted to Northern Asia, and is one of its most peculiar types.

Birds.

97. The ornithology of Northern Asia is even more closely allied to that of Europe than the mammal fauna. Nearly three-fourths of the well-known species of Europe extend throughout Siberia into the islands of the Japanese empire. Here again we have an absence of all tropical forms, and a great development of groups characteristic of cold and temperate regions. One of the most peculiar of these is the genus *Phasianus*, of which splendid birds all the species are restricted in their wild state to Northern Asia. The still more magnificently clad gold pheasants (*Thaumalea*), and the eared pheasants (*Crossoptilon*), are also confined to certain districts in the mountains of North-eastern Asia. Amongst the *Passeres*, such forms as the larks, stone chats, finches, linnets, and grosbeaks, are well developed, and exhibit many species.

Indian region. Mammals.

98. The mammal fauna of the Indian region of Asia is much more highly developed than that of the Palæarctic. The Quadrumana are represented by several peculiar genera, amongst which are *Semnopithecus*, *Hylobates*, and *Simia*. Two peculiar forms of the Lemurine group are also met with. Both the insectivorous and frugivorous divisions of the bats are well represented. Amongst the Insectivora very peculiar forms are found, such as *Gymnura* and *Tupaia*. The Carnivora are likewise numerous; and this region may be considered as the true home of the tiger, though this animal has wandered far north into the Palæarctic division of Asia. Other characteristic Carnivora are civets, various ichneumons, and the benturong (*Arctictis*). Two species of bears are likewise restricted to the Indian region. In the order of Rodents squirrels are very numerous, and porcupines of two genera are met with. The Indian region is the home of the Indian elephant—one of the two sole remaining representatives of the order Proboscidea. Of the Ungulates, four species of rhinoceros and one of tapir are met with, besides several peculiar forms of the swine family. The Bovidæ, or hollow-horned ruminants, are represented by several genera of antelopes, and by species of true *Bos*—such as *B. sondaicus*, *B. frontalis*, and *B. bubalus*. Deer are likewise numerous, and the peculiar group of Chevrotains (*Tragulus*) is characteristic of the Indian region. Finally, this region affords us representatives of the order Edentata, in the shape of several species of *Manis*, or scaly ant-eater.

Birds.

99. The assemblage of birds of the Indian region is one of the richest and most varied in the world, being surpassed only by that of tropical America. Nearly every order, except that of the Struthiones, or ostriches, is well represented, and there are many peculiar genera not found elsewhere, such as *Buceros*, *Harpactes*, *Lophophorus*, *Euplocamus*, *Pavo*, and *Ceriornis*. The Phasianidæ (exclusive of true *Phasianus*) are highly characteristic of this region, as are likewise certain genera of barbets (*Megalæma*), parrots (*Palæornis*), and crows (*Dendrocitta*, *Urocissa*, and *Cissa*). The family *Eurylæmidæ* is entirely confined to this part of Asia.

Ethiopian region. Mammals.

100. The Ethiopian fauna plays but a subordinate part in Asia, intruding only into the south-western corner, and occupying the desert districts of Arabia and Syria, although some of the characteristic species reach still further into Persia and Sindh, and even into Western India. The lion and the hunting-leopard, which may be considered as, in this epoch at least, Ethiopian types, extend thus far, besides various species of jerboa and other desert-loving forms.

Birds.

101. In the birds, the Ethiopian type is shown by the prevalence of larks and stone-chats, and by the complete absence of the many peculiar genera of the Indian region.

Australian region. Mammals.

102. The occurrence of mammals of the Marsupial order in the Molucca Islands and Celebes, while none have been found in the adjacent islands of Java and Borneo, lying on the west of Wallace's line, or in the Indian region, shows that the margin of the Australian region has here been reached. The same conclusion is indicated by the absence from the Moluccas and Celebes of various other Mammals, Quadrumana, Carnivora, Insectivora, and Ruminants, which abound in the western part of the Archipelago. Deer do not extend into New Guinea, in which island the genus *Sus* appears to have its eastern limit. A peculiar form of baboon, *Cynopithecus*, and the singular ruminant, *Anoa*, found in Celebes, seem to have no relation to Asiatic animals, and rather to be allied to those of Africa.

Birds.

103. The birds of these islands present similar peculiarities. Those of the Indian region abruptly disappear at, and many Australian forms reach but do not pass, the line above spoken of. Species of birds akin to those of Africa also occur in Celebes.

Marine mammals.

104. Of the marine orders of Sirenia and Cetacea the Dugong, *Halicore*, is exclusively found in the Indian Ocean; and a dolphin, *Platanista*, peculiar to the Ganges, ascends that river to a great distance from the sea.

Sea fish.

105. Of the sea fishes of Asia, among the Acanthopterygii, or spiny-rayed fishes, the *Percidæ*, or perches, are largely represented; the genus *Serranus*, which has only one species in Europe, is very numerous in Asia, and the forms are very large. Other allied genera are abundant, and extend from the Indian seas to Eastern Africa. The Squamipennes, or scaly-finned fishes, are principally found in the seas of Southern Asia, and especially near coral reefs. The *Mullidæ*, or red mullets, are largely represented by genera differing from those of Europe. The *Polynemi*, which range from the Atlantic through the Indian Ocean to the Pacific, supply animals from which isinglass is prepared; one of them, the mango-fish, esteemed a great delicacy, inhabits the seas from the Bay of Bengal to Siam. The *Sciænidæ* extend from the Bay of Bengal to China, but are not known to the westward. Horse mackerel are numerous. The *Stromateidæ*, or pomfrets, resemble the dory, a Mediterranean form, and extend to China and the Pacific. The sword fishes, *Xiphiidæ*—the lancet fishes, *Acanthuridæ*

—and the scabbard fishes, *Trichuridæ*, are distributed through the seas of South Asia. Mackerels of various genera abound, as well as gobies, blennies, and mullets.

106. Among the Anacanthini, the cod family so well known in Europe shows but one or two species in the seas of South Asia, though the soles and allied fishes are numerous along the coasts. Of the Physostomi, the siluroids are abundant in the estuaries and muddy waters; the habits of some of these fishes are remarkable, such as that of the males carrying the ova in their mouths till the young are hatched. The small family of *Scopelidæ* affords the gelatinous *Harpodon*, or bumalo. The gar-fish and flying-fishes are numerous, extending into the seas of Europe. The *Clupeidæ*, or herrings, are most abundant; and anchovies, or sardines, are found in shoals, but at irregular and uncertain intervals. The marine eels, *Murænidæ*, are more numerous towards the Malay Archipelago than in the Indian seas. Forms of sea-horses (*Hippocampus*), pipe-fishes (*Syngnathus*), fife-fishes (*Sclerodermus*), and sun-fish, globe-fish, and other allied forms of *Gymnodontes*, are not uncommon.

107. Of the cartilaginous fishes, Chondropterygii, the true sharks and hammer-headed sharks, are numerous. The dog-fish also is found, one species extending from the Indian seas to the Cape of Good Hope. The saw-fishes, *Pristidæ*, the electrical rays, *Torpedinæ*, and ordinary rays and skates, are also found in considerable numbers.

Freshwater fishes.

108. The fresh waters of Southern Asia are deficient in the typical forms of the Acanthopterygii, and are chiefly inhabited by carp, siluroids, simple or spined eels, and the walking and climbing fishes. The *Siluridæ* attain their chief development in tropical regions. Only one *Silurus* is found in Europe, and the same species extends to Southern Asia and Africa. The *Salmonidæ* are entirely absent from the waters of Southern Asia, though they exist in the rivers that flow into the Arctic Ocean and the neighbouring parts of the Northern Pacific, extending perhaps to Formosa; and trout, though unknown in Indian rivers, are found beyond the watershed of the Indus, in the streams flowing into the Caspian. The *Cyprinidæ*, or carp, are largely represented in Southern Asia, and there grow to a size unknown in Europe; a *Barbus* in the Tigris has been taken of the weight of 300 lb. The chief development of this family, both as to size and number of forms, is in the mountain regions with a temperate climate; the smaller species are found in the hotter regions and in the low-lying rivers. Of the *Clupeidæ*, or herrings, numerous forms occur in Asiatic waters, ascending the rivers many hundred miles; one of the best known of Indian fishes, the hilsa, is of this family. The sturgeons, which abound in the Black Sea and Caspian, and ascend the rivers that fall into them, are also found in Asiatic Russia, and an allied form extends to Southern China. The walking or climbing fishes, which are peculiar to South-eastern Asia and Africa, are organised so as to be able to breathe when out of the water, and they are thus fitted to exist under conditions which would be fatal to other fishes, being suited to live in the regions of periodical drought and rain in which they are found.

Insects.

109. The insects of all Southern Asia, including India south of the Himalaya, China, Siam, and the Malayan Islands, belong to one group; not only the genera, but even the species, are often the same on the opposite sides of the Bay of Bengal. The connection with Africa is marked by the occurrence of many genera common to Africa and India, and confined to those two regions, and similarities of form are not uncommon there in cases in which the genera are not peculiar. Of Coleopterous insects known to inhabit East Siberia, nearly one-third are found in Western Europe. The European forms seem to extend to about the 30th parallel of N. lat., south of which the Indo-Malayan types are met with, Japan being of the Europeo-Asiatic group. The northern forms extend generally along the south coast of the Mediterranean up to the border of the great desert, and from the Levant to the Caspian.

Domesticated animals.

110. Of the domesticated animals of Asia may first be mentioned the elephant. It does not breed in captivity, and is not found wild west of the Jumna river in Northern India. The horse is produced in the highest perfection in Arabia, and the hot and dry countries of Western Asia. Ponies are most esteemed from the wetter regions of the east, and the hilly tracts. Asses are abundant in most places, and two wild species occur. The horned cattle include the humped oxen and buffaloes of India, and the yak of Tibet. A hybrid between the yak and Indian cattle, called zo, is commonly reared in Tibet and the Himalaya. Sheep abound in the more temperate regions, and goats are universally met with; both of these animals are used as beasts of burden in the mountains of Tibet. The reindeer of Northern Siberia call also for special notice; they are used for the saddle as well as for draught.

Ethnology.

111. Among the later results of scientific research, the demonstration of man's existence on the earth at a period vastly anterior to any of which we have any knowledge through existing records, is one of the most important in giving a solid foundation to the study of ethnology. We have learned that man was the contemporary of many extinct animals, at a time when the main outlines of the land within the area of the present continent of Europe were wholly different from what they now are; and that human societies have been advancing towards their present condition during a series of ages for the extent of which our ordinary conceptions of time afford no adequate measure. Such facts have given an altogether different direction to the current of opinion as to the manner in which the great groups of mankind have become distributed over the areas where they are now found. So, too, the knowledge of the want of stability of forms of human speech has had an important bearing on these same subjects; for the evidence of the modifications which the chief spoken languages have undergone during the historic period shows that there is probably no country in which the tongue in use a thousand years ago would now be intelligible, and leads to the conclusion that even a radical diversity of language need not imply difference of race. In short, the science of ethnology being, like all others, built up on facts only to be obtained by actual observation, requires that these shall be interpreted by an intelligent and constantly repeated review of the whole series of available data as precise knowledge advances.

Mongolian group.

112. Asia, including its outlying islands, has become the dwelling-place of all the great families into which the races of men have been divided. By far the largest area is occupied by the *Mongolian* group. These have yellow-brown skins, black eyes and hair, flat noses, and oblique eyes. They are short in stature, with little hair on the body and face. In general terms they extend, with modifications of character probably due to admixture with other types and to varying conditions of life, over the whole of Northern Asia as far south as the plains bordering the Caspian Sea, including Tibet and China, and also over the Indo-Malayan peninsula and Archipelago, excepting Papua and some of the more eastern islands.

Melanochroic. Xanthochroic.

113. Next in numerical importance to the Mongolians are the races which have been called by Professor Huxley *Melanochroic* and *Xanthochroic*. The former includes the dark-haired people of Southern Europe, and extends over North Africa, Asia Minor, Syria to South-western Asia, and through Arabia and Persia to India. The latter race includes the fair-haired people of Northern Europe, and

extends over nearly the same area as the Melanochroi, with which race it is greatly intermixed. The Xanthochroi have fair skins, blue eyes, and light hair; the others have dark skins, eyes, and hair, and are of a slighter frame. Together they constitute what were once called the Caucasian races. The Melanochroi are not considered by Professor Huxley to be one of the primitive modifications of mankind, but rather to be the result of the admixture of the Xanthochroi with the Australioid type, next to be mentioned.

Australioid. 114. The third group is that of the *Australioid* type. Their hair is dark, generally soft, never woolly. The eyes and skin are dark, the beard often well developed, the nose broad and flat, the lips coarse, and jaws heavy. This race is believed to form the basis of the people of the Indian peninsula, and of some of the hill tribes of Central India, to whom the name Dravidian has been given, and by its admixture with the Melanochroic group to have given rise to the ordinary population of the Indian provinces. It is also probable that the Australioid family extends into South Arabia and Egypt.

Negroid. 115. The last group, the *Negroid*, is represented by the races to which has been given the name of *Negrito*, from the small size of some of them. They are closely akin to the negroes of South Africa, and possess the characteristic dark skins, woolly, but scanty beard and body hair, broad flat noses, and projecting lips of the African; and are diffused over the Andaman Islands, a part of the Malay peninsula, the Philippines, Papua, and some of the neighbouring islands. The Negritos appear to be derived from a mixture of the true Negro with the Australian type.

Distribution of Mongolians. 116. The distribution of the Mongolian group in Asia offers no particular difficulty. There is complete present, and probably previous long-existing, geographical continuity in the area over which they are found. There is also considerable similarity of climate and other conditions throughout the northern half of Asia which they occupy. The extension of modified forms of the Mongolian type over the whole American continent may be mentioned as a remarkable circumstance connected with this branch of the human race.

Tartars. 117. The Mongolians of the northern half of Asia are almost entirely nomadic, hunters and shepherds or herdsmen. The least advanced of these, but far the most peaceful, are those that occupy Siberia. Further south the best known tribes are the Mánchus, the Mongols proper, the Moguls, and the Turks, all known under the name of Tartars, and to the ancients as Scythians, occupying from east to west the zone of Asia comprised between the 40th and 50th circles of N. lat. The Turks are Mahometans; their tribes extend up the Oxus to the borders of Afghanistan and Persia, and to the Caspian, and under the name of Kirghis into Russia, and their language is spoken over a large part of Western Asia. Their letters are those of Persia. The Mánchus and Mongols are chiefly Buddhist, with letters derived from the ancient Syriac. The Mánchus are now said to be gradually falling under the influence of Chinese civilisation, and to be losing their old nomadic habits, and even their peculiar language. The predatory habits of the Turkish, Mongolian, and Mânchu population of Northern Asia, and their irruptions into other parts of the continent and into Europe, have produced very remarkable results in the history of the world, to which further reference will be made hereafter.

Chinese. 118. The Chinese branch of the Mongolian family are a thoroughly settled people of agriculturists and traders. They are partially Buddhist, and have a peculiar monosyllabic, uninflected language, with writing consisting of symbols, which represent words, not letters.

Indo-Chinese. 119. The countries lying between India and the Mongolian area are occupied by populations chiefly of the Mongolian and Chinese type, having languages fundamentally monosyllabic, but using letters derived from India, and adopting their religion, which is almost everywhere Buddhist, from the Indians. Of these may be named the Tibetans, the Burmese, and the Siamese. Cochin-China is more nearly Chinese in all respects.

Malays. 120. The Malays, who occupy the peninsula and most of the islands of the Archipelago called after them, are Mongols apparently modified by their very different climate, and by the maritime life forced upon them by the physical conditions of the region they inhabit. As they are now known to us, they have undergone a process of partial civilisation, first at the hands of the Brahminical Indians, from whom they borrowed a religion, and to some extent literature and an alphabet, and subsequently from intercourse with the Arabs, which has led to the adoption of Mahometanism by most of them.

Aryans & Semites. 121. The name of *Aryan* has been given to the races speaking languages derived from, or akin to, the ancient form of Sanskrit, who now occupy the temperate zone extending from the Mediterranean, across the highlands of Asia Minor, Persia, and Afghanistan, to India. The races speaking the languages akin to the ancient Assyrian, which are now only represented by Arabic, have been called *Semitic*, and occupy the countries south-west of Persia, including Syria and Arabia, besides extending into North Africa. Though the languages of these races are very different they cannot be regarded as physically distinct, and they are both without doubt branches of the Melanochroi, modified by admixture with the neighbouring races, the Mongols, the Australioids, and the Xanthochroi.

Language and religion. 122. The Aryans of India are probably the most settled and civilised of all Asiatic races. This type is found in its purest form in the north and north-west, while the mixed races and the population referred to the Australioid type predominate in the peninsula and Southern India. Among the hill tribes of Central India are some which appear to have a Mongolian origin, and to have come in from the north-east, such as the Koles and Bhils. The spoken languages of Northern India are very various, differing one from another in the sort of degree that English differs from German, though all are thoroughly Sanskritic in their vocables, but with an absence of Sanskrit grammar that has given rise to considerable discussion. The languages of the south are Dravidian, not Sanskritic. The letters of both classes of languages, which also vary considerably, are all modifications of the ancient Páli, and probably derived from the Dravidians, not from the Aryans. They are written from left to right, exception being made of Urdu or Hindustaní, the mixed language of the Mahometan conquerors of Northern India, the character used for writing which is the Persian. From the River Sutlej and the borders of the Sindhian desert, as far as Burmah and to Ceylon, the religion of the great bulk of the people of India is Hindu or Brahminical, though the Mahometans are often numerous, and in some places even in a majority. West of the Sutlej the population of Asia may be said to be wholly Mahometan, with the exception of certain relatively small areas in Asia Minor and Syria, where Christians predominate. The language of the Punjab does not differ very materially from that of Upper India. West of the Indus the dialects approach more to Persian, which language meets Arabic and Turki west of the Tigris, and along the Turkoman desert and the Caspian. Through the whole of this tract the letters are used which are common to Persian, Arabic, and Turkish, written from right to left.

Distribution of Negroids. 123. The presence of the Negroid type in isolated Asiatic areas, so far removed from the existing Negro region, appears to require for its explanation the former extension of dry land from Africa across the area now occupied by the Indian Ocean, and the later disappearance of such land by changes of level of the earth's surface. If, again, the relation of the Dravidian (non-Aryan) population of Southern and Central India to that of Australia be real,—and the relationship seems to be sufficiently established,—the presence in India of this race seems also to require the former occurrence of great alterations in the distribution of sea and land across the equatorial region of the Indian Ocean, and probably an alternation or repetition of movements such as our better knowledge of other parts of the earth shows us to have been normal rather than abnormal. That changes on a very great scale have taken place in Southern Asia in the very latest geological periods is well established, and as was before observed (par. 44), these hypotheses are supported by direct geological evidence, and corroborated by the facts of botanical and zoological distribution.

HISTORY. 124. In looking back on the materials at our command for ascertaining how the existing condition of the earth and its inhabitants has been brought about, we are generally forced to the conclusion that they are but fragmentary and disappointing; this is more especially the case in dealing with our own race. Of historical records there are hardly any that extend to seven centuries before the Christian era, except those in the form of monuments and of fragmentary and obscure inscriptions. What is left of more remote antiquity is little more than the material wreck of human societies; the living forces that carried them forward have necessarily escaped us, except as matter of conjecture.

Prehistoric man. 125. Of prehistoric man little has yet been discovered in Asia; but a sufficient number of stone and bronze implements or weapons has been found in various parts of India to show that the first steps of the human race in civilisation are everywhere almost identical.

Aryans and Semites. 126. The feeble light thrown on the earliest history of the Aryan race exhibits it as a pastoral people occupying the valleys and mountains along the Oxus. In its proximity to the south were the Semitic races, distributed from Syria to the Euphrates and Persia, and perhaps further east. These two races are seen to have spread across Southern Europe, North Africa, and South-western Asia; the Aryans supplying their language to the greater part of Europe and of the temperate zone of Asia, from the Mediterranean to India; the Semites giving theirs to Arabia, Syria, and North Africa. It is supposed that the population of the

Their migrations. area referred to was thus distributed by reason of migrations caused by pressure from Mongolian tribes on the north, such as is known to have arisen since the historical period. Possibly the movements may have been due to changes in the climate, and the gradual diminution of the rain-fall (of which there is evidence), which might have rendered the area originally occupied by the Aryans unable to support them. But it may be regarded as certain that the Brahminical race, formerly dominant in Upper India, entered that country from the north-west as invaders. The ascertained connection of the languages of India and of the intermediate tract with the ancient Aryan or Vedic language, the fact that the founders of the Brahminical faith fixed themselves in or near the mountains of Northern India, the greater predominance of the Aryan type in this region, the separation of a privileged higher from a servile lower class or caste, and the general evidence of the diffusion of Indian civilisation from west to east, with many other circumstances, tend to corroborate such a view. An intrusion of Aryans into the countries originally occupied by the Semites seems also to have taken place in

Languages. Iran or Persia. As the Aryan language developed into the Sanskrit in India, so in Persia it gave birth to the Zendic or Pehlvi, the language of the sacred books of the Fire-worshippers; and as the Aryans seem to have borrowed the Dravidian letters in the former country, so they adopted those of the Semites, or ancient Assyrians, in the other. The European branch of the Aryans, the Hellenic races, likewise appear to have had no letters of their own, and to have borrowed a Semitic alphabet from the Phœnicians. The Bactrian Aryans used an archaic quasi-Phœnician alphabet in North India till 250 B.C., about which time the Pali letters, on which the Devanagari alphabet was based, are known to have been current.

127. The races that formerly occupied the plains of Mesopotamia and the neighbouring mountains—the Babylonians and Assyrians—are, next to the Egyptians, those whose monuments and inscriptions supply the earliest definite records of mankind, going back possibly nearly 4000 years from the present time. These, and the corresponding remains of the Egyptians, which are of even greater antiquity, taking us back perhaps 6000 years or more, indicate that powerful kings then ruled over these countries, with frequent changes in the boundaries of the separate states, under conditions not very greatly different from those that continued until the kingdoms disappeared before the progress of Roman or Mahometan power. How long these races may have taken to arrive at the state of civilisation in which they were as they first become known to us it is impossible to say; but there is nothing to suggest that their condition is to be accounted for otherwise than by prolonged gradual transformations, such as they and all other races are known to have undergone in the time subsequent to that from which our historical records commence. Earliest civilisation.

128. The task of tracing from these remote epochs to more recent times the mutual relations that have arisen between the people of the several parts of Asia and the surrounding countries, leads us to a review of the history of the continent, of which a very brief outline will be attempted. From this we shall see how the progressive races of Europe appear to have had their origin in Asia; how in Asia and Egypt were taken the first steps in human civilisation and learning; how in Asia arose all the forms of religion which have so greatly influenced the history of man,—the Vedantic, the Buddhist, the Hebrew, and, more especially, Christianity and Mahometanism; how the movements of the population of Central Asia have affected the surrounding regions; and lastly, how the condition of almost the whole continent has, from the earliest ages to the present day, been one to invite foreign conquest, and to lead to the supremacy of foreign races over all its parts. General view.

129. The earliest event in Hindu chronology which has any pretence to being called historical is the war of the Máhábhárat. The account of this is contained in a poem, written about 500 B.C., which is one of the Vedas. It seems to have been a contest between two branches of the house reigning in Northern India, and to have occurred about 1400 B.C. The accounts of antecedent periods are manifestly mythical, and merely indicate the probability of the gradual progress of the conquering Brahminical race from west to east. The Vedas are a collection of hymns and heroic poems, containing the religious doctrines of the Aryans at that remote period, and embodying the earliest system of philosophy which we possess. The inroad of Alexander the Great to the Sutlej (Hyphasis) in 350 B.C. affords a landmark in a very obscure past. The Greek colony left in Bactria survived nearly to the Christian era. In 550 B.C. was born, in Northern India, Sakya, the founder of Buddhism. This was a development of the Vedic theology; in the course of two or three centuries it became dominant in India, whence it was carried into Tibet and China, and at length became, and still remains, the religion of the greater part of Asia, though it eventually declined in India, and has now almost entirely disappeared from the Hindu chronology.

country of its origin. Asoka, one of the Hindu kings of whom memorials exist in inscriptions found in various parts of India, lived when Buddhism was triumphant, in 250 B.C. The subsequent annals consist of little more than lists of kings of various dynasties settled in various parts of the country, until we reach the period of the Mahometan conquests.

Western Asia.

130. Of the western parts of Asia it will suffice to say that about 600 B.C. the kingdoms known under the names of Babylonia, Assyria, Media, and Persia, began to coalesce, and were at length united under Cyrus, the Persian; the "Great King," whose territories are said to have extended from the Mediterranean to the Indus.

During this period the civilisation and learning of Egypt and Western Asia had penetrated into Greece, where was developed, from the branch of the Aryan race which occupied that country, the most extraordinarily intellectual community which has ever existed. The successful resistance of Greece to the advance of the Persians probably prevented the spread of the western-Asiatics over Europe, and left that continent open to the evolution of the far higher type of civilisation which is its characteristic. The destruction of the Persian monarchy by Alexander took place about 330 B.C. After the Indian expedition and death of the great Greek conqueror, his Asiatic kingdom fell to pieces, and numerous petty sovereignties were formed out of it. About fifty years before the Christian era, the Romans for the first time appeared on the arena of Asia, took possession of Syria, and soon after occupied a large part of Asia Minor, and at length established themselves on the Tigris. During this interval the more eastern part of the old Persian kingdom, called by the Romans Parthia, had again acquired an independent existence, and its monarch, once more assuming the title of the "Great King," fruitlessly attempted to drive the Romans out of Asia. In the year 274 A.D. later successes of the Romans in the East were celebrated by the famous triumph of the Emperor Aurelian, in which, it is said, ambassadors appeared from all parts of Asia, even from China. The conflicts between the Persians and Romans continued long after the division of the Roman empire, 395 A.D., without any material change of the boundaries of the contending parties. The Romans or Byzantines never advanced beyond Armenia or the Tigris; nor could the Persians permanently retain possessions to the west of those limits, though once (620) they had penetrated to the walls of Constantinople.

Greece and Persia.

Rome and Persia.

Origin of Christianity.

131. While these conflicts were in progress, events of an altogether different character had arisen, which have brought a small portion of Western Asia into prominent notice in the world's history. Christianity had its origin in Syria, among the Jews, a tribe of Semitic race, whose sacred writings and history are of extreme antiquity, and have been preserved and are well known by reason of the special interest created in them. The Christian faith spread rapidly over Asia Minor, and soon extended to all parts of the Roman empire, in which it was at length accepted as the state religion about 320 A.D.

Its influence.

132. Among the efficient agencies of Western progress no doubt can exist that Christianity was one of the most active. It necessarily happened that the religion which established itself on the ruins of the superstitions of the Old World should have an important influence on the new forms of society that arose; and as the Christian faith gradually became the dominant and at length the only religion of Europe, it shared greatly, both through its doctrines and its organisation, in bringing about the intellectual and social advance that has there taken place.

Origin of Mahometanism.

133. But Christianity, though it had its origin in Western Asia, has produced no such consequences there. The progress which it had made to the eastward during the first six centuries was very soon after cut short by the founding of a rival proselytising religion by Mahomet, 620 A.D., whose followers and successors effectually arrested the spread of the Christian faith in this direction.

Its spread.

134. The Arabs, under the influence of the fanatical preachings of their prophet, now burst forth upon the countries around them; in less than a century, 730 A.D., they had possessed themselves of Persia and Transoxiana, penetrated to the Indus, driven the Byzantine armies out of Asia Minor and Syria, overcome Egypt, advanced along Northern Africa to the Atlantic, had conquered Spain, and even entered France. Nor was this a mere temporary success. Though the Arabs were at once repelled from France, the Mahometans held their ground in Spain for more than seven centuries, and have not only been dominant to the present day in all other parts of their earliest conquests, but have since added largely to the area in which the religion of Mahomet has been adopted.

Its influence.

135. It was to the immediate successors of Mahomet that our race is indebted for the impulse given to science, which was so long wholly neglected or deliberately condemned by Christian authority in Europe. But although it is not possible to say that Mahometanism has been without beneficial tendencies or results, yet the general history of Mussalman races has been marked by horrible barbarities and utter disregard of human life. The annals of Asiatic kingdoms present us, for the most part, with a succession of unscrupulous tyrants, among whom have appeared, at most, two or three sovereigns under whom anything like real progress towards civilisation was possible. And, admitting that rulers of all races and religions have in turn exhibited qualities which can only be regarded with reprobation, and that it is not easy to discriminate between what is due to the influence of race and what to that of religion, it is certain that the Mahometan Mongols to whom Asia was for centuries a prey far outstripped, in the violation of the principles on which civilisation is based, all other communities in any part of Europe or Asia.

Successors of Mahomet.

136. The Arab empire, under the khalifs of Baghdad, culminated about 800 A.D., but hardly maintained its integrity fifty years more. On its disruption a Turki dynasty established itself in Ghazni, from which sprung Mahmúd, who first invaded India in 1001, and extended his rule to the Oxus and Persia. His successors (not descendants) established the Mahometan kingdom of Delhi in 1200, which gradually extended over all Northern India in the next two centuries. After Mahmúd's death another Turki house, that of the Seljuks, established itself in Persia, Asia Minor, and Syria, about 1050, extended its authority to Egypt 1170, and retained its vitality till 1300. The Crusades, between 1100 and 1300, set up a small Christian power in Syria, with which the Seljuk Turks were in a state of almost constant conflict, the famous Saladin (Sálah-u-din) having been one of their chiefs. In the wars between the followers of the crescent and the cross, it is hard to say which party inflicted the greatest atrocities on the unfortunate inhabitants of the country around the Holy Sepulchre.

Chenghiz Khán.

137. Two centuries before the Christian era the Mongolian races of Central Asia are known to have begun the series of predatory incursions on their neighbours, which so long made them the terror of all parts of the Old World less barbarous than their own. The most important of these irruptions took place about 1220. Chenghiz Khán, a Mongolian chief, having made himself master of Central Asia, established his capital at Kárakorum, the precise site of which is doubtful. In 1215 he took possession of Northern China, and then turned westward; he overran the whole of Turkistan, the countries along the Oxus, Afghanistan, and Persia, and

added them to his empire. After his death, in 1227, his successors, dividing his kingdom among them, continued their advance to the west. They swept away the remains of the Arab khalifs of Baghdad in 1258; and overthrew the Seljuks in Asia Minor in 1300; several of their expeditions for plunder reached India; and they spread themselves over South-eastern Europe, into Russia, Hungary, and Poland, and entered Siberia. During this interval, as they became settled, they abandoned the simple deistical faith of their fathers, and adopted the religion of the races they had conquered.

Timur. 138. In the year 1370 there rose, above the ordinary level of the successors of Chenghiz, another chief, who claimed descent from the great khan, but was more indebted for his position to his own force of character. From an obscure position in Samárkhand, Timúr, commonly spoken of as Tamerlane by European writers, had acquired in the course of twenty years the sovereignty of Afghanistan, Transoxiana, of Persia as far as the Euphrates, and of Eastern Turkistan to Káshgar. His armies reached to Siberia, and he carried his devastations into the heart of Russia, almost to the walls of Moscow. In the years 1398–99, excited by fanaticism and the love of rapine, he made his celebrated march into India, an account of which, with his other exploits, exists, written by himself. He plundered and burnt Delhi, which city was surrendered under a solemn promise of protection; he carried off innumerable captives, ravaged the neighbouring country, and massacred the Hindu inhabitants to wash out the stains of Mussulman blood spilt by his sword; and finally quitted India, leaving anarchy, famine, and pestilence behind him, having in four short months overwhelmed the provinces of Northern Hindustan by calamities which prostrated the kingdom of Delhi for nearly a century. From these ruins the ruthless barbarian turned to the extreme west of Asia, which he ravaged with greater ferocity, if possible, than India. After the overthrow of the Seljuk Turks in 1300, the descendants of Chenghiz ruled in Asia Minor for some years. Amid the disorders that accompanied the successions of this dynasty, there started up another adventurer, Osmán or Othman, who established himself in the north-western region of Asia Minor, overlooking the Euxine and Sea of Marmora. The descendants of Osman had already become important chiefs, in 1360, when they had driven the Byzantines out of Asia and, under Amurath, established themselves in Europe in the provinces adjoining Constantinople, and had also extended their sway eastward to the Euphrates. It was against Bajazet, the successor of Amurath, that Timur turned his arms (1400). Aleppo and Damascus were utterly destroyed by him. From Syria, passing the plains of Mesopotamia, where it is said he erected a pyramid of 90,000 heads on the ruins of Babylon, he pursued the Osmanlis into Anatolia; there Bajazet was defeated and made prisoner. Timúr having established his supremacy throughout Western Asia and made the Greek emperor his tributary, turned back to Samárkhand, and died in 1405, on his way to attack China. The successors of Bajazet soon recovered their hold on Asia Minor and Syria, and in 1453 took Constantinople, and put a final end to the Byzantine power, establishing in its place the Ottoman empire, extending over Greece, the Danubian provinces, and Asia Minor.

King's of Delhi. Babar. 139 Turning once more to India, we find the kings of Delhi still in a feeble condition in 1526, when Bábar, the sixth descendant of Timúr, and on his mother's side of the family of Chenghiz Khan, who had established himself at Cabul, marched upon Delhi, defeated the king at Paniput, and made himself master of Northern Hindustan. On this occasion cannon were first used in war in India. On his death, Cabul with the Punjab were separated from the kingdom of Delhi, and after some years of disorder in the succession, the Indian sovereignty came into the hands of his grandson Akbar, 1556, who has been justly spoken of as taking a place among that rarest order of princes whose reigns have been a blessing to mankind. He died in 1605, having re-established the Mogul kingdom of Delhi over all Northern India, from Candahar to Bengal, and as far south as the Deccan. He was remarkable alike for his learning, his tolerance, his justice, the excellence of his personal character, and his administrative capacity; and it may truly be said that the foundations of the present system of government in Northern India were laid by this great man, who for the first time really consolidated the kingdom, and established an organised administration. Akbar.

140. Akbar's successors, among whom may be named Shah Jehan as being but little less eminent than his grandfather, ruled in India till 1748, extending their power further south, over nearly the whole of the peninsula, but with various reverses and a gradual decay of strength. The Mogul dynasty dragged on a feeble existence, till it virtually fell before the Mahrattas; after this it maintained for a few years a sovereignty little more than nominal, and finally disappeared on the establishment of the British power in Northern India. Among the more notable incidents in this interval are the establishment of the Mahratta government in the Deccan under Sevaji in 1647, and that of the Sikhs at Lahore in 1708 (the founders of the religion having lived, Nanuk in 1419, and Gurú Govind in 1675), and the third sacking of Delhi by Nadir Shah, the king of Persia, in 1739. Later Indian history.

141. Nothing is more remarkable in the history of human societies than the manner in which the ancient civilisation of India has maintained itself through the centuries which have elapsed since the inroads from the West began, the records of which form so large a part of Indian history. Long before the time to which the annals of any part of Europe go back, India had made considerable material and intellectual progress, and the fundamental characteristics of the community at present are probably but little different from what they were 2000 or 3000 years ago. The natural wealth of the country, its open character, and the smaller energy and physical force of its inhabitants, have made it a continual prey to the more warlike nations without, and constant internal wars have completed its political disorganisation, so that the remains of any truly national governments have, with few fragmentary exceptions, long ceased to exist. But probably few countries that have been subjected to such vicissitudes have changed so little. The well-being of the indigenous population has been preserved in a remarkable degree by that inaptitude to change which appears to be inherent in their race, and which suggests the necessity of the efflux of a very long period of time for the growth of those customs, which have been so little modified since they became fixed in the form described in the ancient Sanskrit writings. Inaptitude of Indian races to change.

142. The early history of China offers little to call for remark in such a review as the present. The date of the writings of Confucius is fixed at 550 B.C. The great wall, constructed to oppose the inroads of Mongols from the north, was a work of the Hán dynasty about 200 B.C. About 585 A.D., the whole of China was united into one empire, having previously been governed by many petty chiefs. The first successful invasion of the Mongols under Chenghiz Khan took place in 1234 A.D., and he retained possession of the northern half of the empire, handing it to his son, Kublai-Khan, in 1260, who completed the conquest of the whole country in 1279, and founded the Mongolian dynasty. In his reign Marco Polo, the Venetian traveller, visited China.

China, having traversed the whole of Asia, and from him are derived our first authentic accounts of those countries. The Mongolian dynasty fell, from internal insurrection, in 1366 A.D., when a national government was again set up, once more to be overthrown by an invasion of the Mânchus from the north, about 1643, when commenced the Manchu dynasty, which has existed till the present time, and from the establishment of which the political importance of the Chinese empire began. The supremacy of the present dynasty of China over Central Asia, and the neighbouring states of Eastern Turkistan, dates apparently from about 1680; but it has recently been thrown off in the extreme west by the Turkish races, and is very doubtfully maintained in other distant provinces, and has further been seriously limited in late years by the advances of Russia.

Japan. Formosa.

143. The islands of Japan have maintained an independent position from remote antiquity. Formosa is half occupied by the Chinese, half in possession of indepeudent tribes. The whole island has quite recently, after a threatened conflict with Japan, been recognised as subject to China.

Indo-Chinese nations.

144. Of the earlier history of the Indo-Chinese nations little is known. The kingdoms are politically insignificant, and the physical peculiarities of the territories on which they are established make foreign invasion by land almost impossible, and internal communication and intercourse with the rest of the world, except by sea, difficult.

Malays.

Similar remarks apply to the Malay Archipelago.

Review of history of Asia.

145. The history of Asia thus far is the record of events brought about by the conflict of forces almost wholly developed within the continent itself. But external influences came into operation by which an altogether new set of conditions was created, leading to consequences among the most remarkable of any in the world's history. The germs of civilisation, which had their origin in Western Asia and Egypt, were thence carried by the Greeks into Europe. In Asia arose the first systems of religion and conceptions of philosophy, which have given scope and food to man's intellectual development; and in it were taken the first steps in the formation of the sciences of observation. But it is to Greeks, instructed in Asiatic learning, that the world is indebted for its further advances. And as Asia no more contributed to this movement which she had started, so she had but little share in its results, or in the benefits it conferred on mankind. Her history presents an unceasing repetition of barbaric invasions, instigated by the love of plunder, which swept, wave after wave, over the most fertile and populous provinces where civilisation and wealth had begun to appear, and left ruin and demoralisation in their departing track.

Backward civilisation.

It may well be doubted whether Asia, speaking generally, had made any permanent advance in the arts of civilisation since the disruption of the Roman empire, until those events occurred which have brought her under the immediate influence of the powers of the West, and which may prove to have given the whole continent a lasting impulse towards progress. These events are the establishment, little more than a century ago, of British supremacy in the south, and still later of that of Russia in the north.

Russian power in Asia.

146. The extension of Russian authority into Northern Asia began about the year 1700, and by the end of the century Russian settlements extended across Siberia to Kamchatka. The advance of this power on the west of Asia into the borders of Turkey, Persia, and Turkistan, and on the east into the outlying provinces of China, is of much later date, and must be regarded as a natural and necessary consequence of the position of a powerful and civilised state brought into contact with barbarous neighbours.

Maritime discoveries.

147. The first introduction and subsequent growth of European power and influence in Eastern and Southern Asia have been almost wholly the result of maritime discovery and enterprise. Under the stimulus of expected commercial gain, and guided by the intelligence of mariners who, like Columbus, were acquainted with the astronomical teachings of the Arabs, and who, in defiance of the Christian church, believed in the sphericity of the earth, the first of a great series of voyages of discovery was undertaken, which in 1492 gave to Europe its knowledge of America.

Their effect.

A few years later the discovery of the passage round the Cape of Good Hope by Vasco di Gama, in 1498, opened out Asia to the commercial enterprise of the maritime nations of Europe. The trade with the East, which had hitherto found a route overland along the Black Sea and Caspian, or up the Red Sea by Egypt, or by the Persian Gulf to Syria, and had been seriously affected by the irruptions of the Mongols, had been centred with the merchants of Genoa and Venice. The opening of the sea route destroyed the monopoly previously established by the Italians, and the Portuguese naturally were the first to benefit by their discovery. The other maritime nations soon followed in their track. A new impetus was thus given to intercourse with Asia, which in a short time altogether changed the current of events in that continent.

Progress of Portuguese.

148. The Portuguese landed on the Malabar coast of Hindostan in 1498, and speedily made themselves masters of the Indian Ocean, which they swept with their fleets from Arabia to China. They took Ormuz and Aden, became supreme on the Malabar and Coromandel coasts, in Ceylon and the Malayan islands, and established powerful settlements at the mouth of the Ganges. They first reached China in 1516, and were permitted to establish about twenty years later a factory at Macao, which they still maintain. From that time the intercourse between China and Europe by sea has been regularly and gradually extended. The power of the Portuguese in India, after lasting nearly a century, fell into insignificance, partly by the arms of the Mahometans, partly by the efforts of the Dutch and English—to which latter nation they ceded the island of Bombay in 1661, on the treaty of marriage of Charles the Second.

Other nations.

149. The Dutch, the Danes, the Spaniards, the French, and the British, all acquired in a similar manner, and (excepting the Danes) still retain settlements of various degrees of importance in India, the Malay peninsula and Archipelago, and China, of which those of the British in India, Ceylon, and China, of the Dutch in Java and the neighbouring islands, of the French in Camboja, and the Spaniards in the Philippine Islands, alone call for mention. The celebrated Jesuit missionaries, who were long the only authorities on China, first reached Canton in 1579, though Christian teachers had penetrated into the country several centuries before, even, it is said, as early as 635 A.D., and churches were built and converts made in 1274, as reported by Marco Polo. The Jesuits, from their superior knowledge, soon made themselves a powerful body in the state, and their influence was great till about 1700, after which, owing at first apparently to conflicts regarding the limits of the Pope's jurisdiction over Chinese, they lost favour, and eventually were subjected to positive persecution. They have never regained their former authority. The later intercourse of Europeans with China has introduced some of the forms of Western progress, and opened the empire to commerce.

East India Company

150. The history of the British settlements in India calls for more detailed notice. The English East India Company was founded in the reign of Queen Elizabeth, in 1599, with a purely commercial aim. For 150 years the Company confined itself to extending its trade, but the difficulties of protecting the operations of commerce in the midst of such anarchy as prevailed in the provinces in which their settlements were, at length forced them to arm

in defence of their factories. The example and rivalry of a powerful foe, the French East India Company, first led them to take an active part in the political intrigues of the numerous native chiefs, and from this, step by step, a simple body of traders has been transformed into a recognised branch of the British Government, exercising supreme authority over the whole of India from the Indus to the Malay peninsula.

French India Company.

151. The French Company, established in 1664, had existed side by side with that of the English in complete harmony for 70 or 80 years, though the two nations had been repeatedly at war in Europe. But in 1744 the war which then broke out was carried into India by the French, with consequences which the most far-seeing could not have predicted. The French governor of Pondicherry, Dupleix, a man of genius and ambition, formed the project of founding a French empire in the Deccan, a project which, under the efforts of a succession of able men, at one time seemed about to be realised. But after a struggle of fifteen years, during which both sides formed alliances among the more powerful native states, the English finally defeated the French in 1760, and destroyed their settlements. Two years later, on the restoration of peace, the French were permitted to re-occupy their former factories. But the opportunity of taking a place as the paramount political power in India was gone, nor were their later efforts, which were continued till 1802, more successful.

Ruin of French influence.

Growth of power of British.

152. On the other hand, the English Company, with the military aptitudes and experience developed among its servants in these contests, was brought more and more into contact with the many self-constituted chiefs who with more or less pretence of a nominal allegiance to the puppet emperor of Delhi, had carved out for themselves kingdoms from the ruins of the Mogul empire, and subjected all parts of India to rapine and violence. The results of the conflicts that ensued were to add fresh strength to the Company. The battle of Plassy, in 1757, gained by the British under the celebrated Clive over the viceroy of Moorshedabad, made them masters of Bengal and its dependencies. From that date the history of the Company is a record of the gradual subjugation of all their opponents. The Delhi sovereignty had already entirely fallen to pieces, and the British became by the force of events the paramount power in India, and on them have devolved all the duties and responsibilities of that position.

British become paramount.

Character of government.

153. From the commencement of the present century the main scope of the action of the East India Company was the introduction of order and good government into the countries that had fallen under its rule; and since the final destruction of the predatory armies of the Pindarees in 1817–18, India has enjoyed, with few and short exceptions, a condition of internal peace such as had never been approached in any part of its previous history. Under such circumstances the wealth of the country has enormously increased, and the progress of civilisation in all its branches has been great and continued; and it may be truly affirmed that nowhere has there been established by any race of foreigners a rule more beneficent and unselfish, or better designed to advance the best interests of the subject population, than that which has now existed under Great Britain for upwards of a century over a large part of Southern Asia.

(The numerals refer to the paragraphs.)

ASIA MINOR

See Plate II. vol. xv

ASIA MINOR is the name commonly given by geographers to the portion of Western Asia which projects from the main mass of the continent towards the west, between the Black Sea and the eastern basin of the Mediterranean, and which at its north-western extremity approaches so closely to Europe as to be separated from it only by the two narrow straits of the Bosphorus and the Dardanelles. It is situated between 36° and 42° of N. lat., and between 26° and 40° of E. long., and is about equal in superficial extent to France, while it is but little inferior to the peninsula of Spain and Portugal, with which it offers some striking analogies. But while its boundaries on three sides—the Black Sea on the N., the Ægean Sea or Archipelago on the W., and the Mediterranean on the S.—are clearly defined by nature, its eastern boundary is wholly arbitrary and uncertain. The ranges of mountains which extend from the Gulf of Scanderoon, at the north-eastern extremity of the Mediterranean, across to the Black Sea near Trebizond, are so far from forming a continuous range like the Pyrenees, that they are broken into a number of irregular groups and masses, some of which may be regarded as continuations of the Taurus on the south, while others are connected with the highlands and mountain ranges of Armenia on the north; and the great river Euphrates forces its way through the central mass of mountains, nearly at right angles to the general direction of the chain. Hence it is impossible to separate Asia Minor on this side from the adjoining regions of Armenia and Mesopotamia by any real or physical boundary, and for this very reason the political limits have in all ages been very vague and fluctuating. For the purpose of geographical description it may suffice to take a line roughly drawn along the mountain ranges from the Gulf of Scanderoon or Issus to the Euphrates, between Samosata and Malatiyeh, thence to follow the line of that river to the point near Erzinjan where it first turns to the south, and thence to draw an imaginary line to the Black Sea, a little to the eastward of Trebizond. The tract extending along the coast eastwards from the latter city to Batoum, though included within the limits of Turkey in Asia, belongs in a geographical sense to Armenia rather than to Asia Minor. But whatever line of demarcation be assumed, it must be carefully borne in mind that it does not correspond to any natural boundary.

The term Asia Minor, notwithstanding its ancient form, is of comparatively modern introduction, and was unknown to the principal Greek and Roman geographers. Orosius, who wrote early in the 5th century, was the first writer who employs the term in this sense, and he introduces it in a manner that shows it was not yet in general use. The name of Asia was, indeed, specially applied from a much earlier period by the Romans to the province which they constituted out of the Greek kingdom of Pergamus, and which was extended by subsequent additions till it comprised a large portion of the peninsula, but it was never at any time coextensive with the geographical region we are considering, nor do we find the distinctive epithet of Minor applied to it before the time of Orosius.

The name of Anatolia, which is not unfrequently used by modern geographers as synonymous with Asia Minor, is obviously a Greek term derived from ἀνατολή, the sunrise, and thus corresponding exactly to the modern term of "*the Levant*." It appears to have first come into use under the Byzantine empire, and is first found in the works of Constantine Porphyrogenitus in the 10th century. It has been retained in general usage by the Turks, but is employed very irregularly, being sometimes applied in an administrative sense only to the portion of the peninsula westward of the Halys, at other times extended even beyond the limits which we have assigned to Asia Minor. The use of the latter appellation is therefore decidedly preferable as a geographical term.

The territory comprised within the limits above proposed is about 650 English miles in length, from Malatiyeh on the Euphrates to the promontory opposite the Island of Scio; but if the line be drawn from Cape Sigeum, at the entrance of the Dardanelles, to the boundary beyond Trebizond, the distance amounts to more than 720 miles. Its greatest breadth from Cape Anamur (Anemurium) on the south coast, to Cape Kerembeh (Carambis) on the north, is just about 6° of latitude, or 420 English miles; but a line drawn from the head of the Gulf of Scanderoon to the nearest point of the Black Sea (at Ordu) does not exceed 300 miles. This may, therefore, be considered as the isthmus by which the peninsula of Asia Minor is joined to the main continent. But very erroneous notions prevailed in ancient times, and even down to a comparatively recent date, with regard to the width from sea to sea, so that the peninsular character of the region to the west of it was greatly exaggerated. Herodotus stated that it was only five days' journey for an active man from the east of Cilicia to Sinope on the Euxine; other authors extended this to seven days; and Pliny gives the distance from Amisus to the Gulf of Issus at only 200 Roman miles (about 185 English miles). Even in the last century the great geographer D'Anville diminished the width of the isthmus between the two seas by a whole degree, or about 70 English miles.

Asia Minor, therefore, can only be termed a peninsula in the same vague and general sense in which that expression is applied to the peninsula of Spain and Portugal. It has been already observed that there are several points of analogy between the two, not only from their forming respectively the westernmost portions of the two continents of Europe and Asia, and occupying much the same position in latitude, but still more in regard to their general conformation and structure. In both cases the interior of the country is occupied by a vast table-land, which forms, as it were, the nucleus of the whole, while ranges of mountains border this elevated tract on all sides, and these again are separated from the sea by valleys or plains at a low level, which are in many cases regions of surpassing fertility. The central plateau of Asia Minor is, however, more extensive than that of the Spanish peninsula, and occupies a much greater portion of the whole country. Beginning on the east with Cappadocia, the whole of which extensive province is more than 3000 feet above the sea, it is continued to the foot of Mount Taurus, by the high table-lands of Lycaonia and Isauria, the former of which is even superior in elevation to Cappadocia; while to the north of these two districts it comprises the whole of Galatia, and by far the greater part of Phrygia, together with portions of the adjoining provinces of Mysia and Bithynia. No part of this extensive region is situated less than 2000 feet above the sea, except where it is occasionally cut into by deep valleys on its northern or western borders.

A tract of such great extent naturally presents great diversity of surface, and is not only varied by extensive undulations, and occasionally by deep valleys, but is traversed in different directions by numerous ranges of mountains, some of them rising to a considerable altitude above the ordinary level of the surrounding plains. These ranges separate the different portions of the great central plateau from one another, and thus divide them into several basins, the waters of which have no direct communication with each other. One of the most remarkable features in the physical geography of the interior is the fact, that one of the basins thus parted off from the rest, extending nearly 250 miles in length and 150 in breadth, from the sources of the Sangarius and Halys on the north to the great chain of Mount Taurus, has no communication with the sea,—the streams by which it is watered having no outlet, and consequently forming a chain of lakes extending from near Synnada in Phrygia through the whole of Lycaonia, to beyond Tyana in Cappadocia. The most considerable of these lakes is that called, by Strabo, Tatta, and by the Turks, Tuzlah, or the Salt Pan,—an epithet well deserved from its extreme saltness, which exceeds even that of the Dead Sea. It is about 45 miles in length by 18 in breadth, but varies much with the season, being very shallow, so that a considerable portion of its surface is dry in summer and covered with incrustations of salt.

North of the region of these lakes lies a dry and naked tract, consisting principally of undulating downs, traversed by the branches and tributaries of the Sangarius and Halys, but otherwise scantily supplied with water, and almost wholly destitute of trees. A portion of this region was in ancient times specially designated as Axylus, or the woodless; but the same epithet might with almost equal propriety be applied to the whole tract extending from Dorylæum and Cotiæum, through the north of Phrygia and Galatia, to the confines of Pontus and Cappadocia, a distance of nearly 300 miles. These vast treeless downs afford pasturage at the present day, as they did in the time of Strabo, to numerous flocks of sheep, but they are for the most part uncultivated, and in many places utterly barren and desolate. The few towns that are found within their limits are, however, sometimes surrounded by luxuriant gardens and fruit-trees in great variety.

Mountains.—The orography of Asia Minor is extremely complicated, and is still but imperfectly known, though the researches of recent travellers, especially of Hamilton and Tchihatcheff, have of late years thrown much light on the subject. But very few of the highest ranges have as yet been accurately measured, and the barometrical determinations of the altitudes of numerous points in the interior, which have been made by Hamilton, Ainsworth, and Tchihatcheff, often differ so much from one another, as to render it doubtful how far we can place reliance upon them. At the same time, we are now able, in a general way, to describe and distinguish the more important mountain ranges of the peninsula—a task for which there existed no sufficient materials down to a late period.

By far the most important of these mountain ranges, and that which constitutes one of the leading geographical features of Asia Minor, is the great chain known to modern as well as ancient geographers by the appellation of Mount Taurus. Beginning at the south-western extremity of the peninsula, in the province of Lycia, it extends in a direction nearly parallel with the south coast as far as the south-eastern angle at the confines of Cilicia with Syria,—a distance, as measured on the map, of more than 7° of longitude, or above 400 English miles. Throughout this extent it forms a continuous range of very considerable elevation, constituting a complete natural barrier between the Mediterranean and the great upland plains of the interior; while in some parts, as in Lycia and the western portions of Cilicia, it sends down numerous arms and branches quite to the sea-shore: in others, on the contrary, leaving a broad strip of alluvial plain between the foot of the mountains and the sea. Its positive elevation is very imperfectly known, none of the summits of the great central range having as yet been measured with any degree of accuracy, and the numbers given in the best maps resting only on the more or less vague estimates of different travellers. It is probable, however, that throughout the greater part of its extent the summits of the main range attain to an elevation of from 7000 to 8000 feet, while many of the higher summits are estimated to exceed 10,000, and in some instances, at least, to approach to 11,000 feet.

The only portion of the Taurus which has yet been examined with much care is that contained within the ancient province of Lycia. Here, as is observed by Strabo, the whole country is occupied by the ramifications of the great chain, which descend in numerous arms and branches quite to the sea, leaving between them only narrow valleys and alluvial plains of very small extent at the mouths of the different rivers. In this instance, as in many similar cases, several of these offshoots and outliers of the main chain attain to a greater elevation than the summits of the central range itself. Thus it is stated, that while the peaks of the Lycian Taurus, which walls off the great mountain table-land of Asia Minor, do not much exceed 7000 feet, the mountain mass of Massicytus (Ak-dagh), which forms the eastern boundary of the Xanthus valley, attains to 10,000 feet; Soosoos-dagh, east of the preceding, rises to between 8000 and 9000 feet, and the highest point of Mount Solyma (Bai-dagh), which rises immediately to the west of the Gulf of Adalia, attains to 10,500 feet (Spratt and Forbes's *Lycia*). It is obviously impossible to fix precisely the natural termination of the Taurus in this part of Asia, these various ridges expanding from the central chain much in the form of a fan. The Gulf of Macri (the Glaucus Sinus of the ancients) is often taken as marking its limits to the west, but in reality, the ridges which descend from the central table-land to the sea opposite Rhodes, as well as to Cnidus and Halicarnassus, are all ramifications of the Taurus, and any one of these headlands might with equal propriety be chosen as the first commencement of the great mountain chain. The popular notion among the ancients, which regarded Cape Chelidonia (the south-eastern promontory of Lycia) as the termination of the Taurus, is deservedly censured by Strabo, who regards the chain as prolonged to the Peræa of the Rhodians.

One of the characteristic features of the Lycian Taurus, which is found also throughout the whole range, is that of the frequent occurrence of basin-shaped valleys, called by the inhabitants "yailahs," sometimes containing mountain plains of considerable extent, walled in on all sides by limestone mountains, and having no outlet for their waters, which in consequence pour themselves into the precipitous cliffs that surround them. These yailahs vary in elevation from 2000 to 6000 feet, and afford excellent pasturage, on which account they are the summer resorts of the wandering tribes of Turcomans and Yourouks. Almost the whole mass of the Taurus is composed of limestone, belonging to the same great formation which constitutes the greater part of the Apennines, as well as of the mountains of Greece, and is generally known to geologists by the name of scaglia, or Apennine limestone. The streams which descend from thence to the sea, and which in many cases have had subterranean courses of considerable extent, are so strongly charged with carbonate of lime that they form vast deposits of travertine; and the level plains intervening between the foot of the mountains and the sea, instead of being composed, like ordinary alluvial plains, of loose detritus and soil, consist of solid deposits of travertine rock of an extent unknown elsewhere. The whole plain of Pamphylia, at the foot of the mountains of Pisidia and Isauria, is thus constituted, and a considerable part of the plains of Cilicia is composed of similar materials.

The principal passes across the chain of the Taurus which are deserving of notice, are the following:—1. That which crosses the chain from the plain of Cibyra (a portion of the great upland tract of Phrygia, at an elevation of 3500 feet above the sea) into the valley of the Xanthus in Lycia, and descends to the city of the same name. 2. That which leads from Afiom Kara Hissar, in the centre of Phrygia, by Isbarta and the ruins of Sagalassus, to Adalia on the Mediterranean. This is one of the most important lines of route in Asia Minor, being the high road from Constantinople to the flourishing seaport of Adalia, at the present day one of the chief ports on the south coast of Asia Minor. 3. A route leading from Konieh (Iconium) by Karaman (Laranda) to Mout, in the valley of the Calycadnus, and thence to Kelenderi (Celenderis) on the coast of Cilicia. This was the route followed by Colonel Leake in 1800, and is the most direct line of communication with Cyprus. 4. The celebrated pass called the Cilician Gates (Pylæ Ciliciæ), which is not only the direct route from Konieh and Kaisariyeh on the north, to Tarsus and Adana on the south of the Taurus, but has been in all ages the great highway from Asia Minor into Syria and the valley of the Euphrates. It is a narrow gorge or defile between two lofty mountain masses, and derives great military importance from its being easily defensible, while it absolutely commands the entrance into Asia Minor on this side. Hence it is mentioned as a point of special interest during the march of the younger Cyrus towards the Euphrates, as well as in the advance of Alexander previous to the battle of Issus. In modern times it was strongly fortified by Ibrahim Pasha, during the short period for which the Egyptians held possession of Syria (1833–1840); but these fortifications have since been abandoned.

This celebrated pass, which crosses the central ridge at an elevation of only about 3300 feet, marks the line of separation between two of the loftiest masses of the mountain chain, the Bulghar-dagh on the west and the Ala-dagh on the east, both of which are estimated to attain to a height of from 10,000 to 11,000 feet. Thus far the mountain range of the Taurus may be considered as forming a continuous chain, the boundaries and direction of which may be readily described. But from this point its character is altogether changed, and it is very difficult to determine, among the numerous mountain masses which are found on the borders of Asia Minor and Syria, which is most properly entitled to be regarded as the main chain of the Taurus. Strabo, the only ancient writer who appears to have had any clear ideas on the subject, describes the Taurus as sending forth two distinct branches,—the one called Mount Amanus to the south, which bounds the Gulf of Issus, and forms the limit between Cilicia and Syria; the other, to which he gives the name of Anti-Taurus, striking off in a north-easterly direction through the eastern portion of Cappadocia, and gradually sinking into the plain. This last chain is clearly the one which forms the continuation of the Ala-dagh towards the north-east, between the valley of the Sarus and that of the Halys, and is continued, though at a lower elevation, till it joins the mountains that separate Pontus from Armenia. The name of Taurus is given by the Greek geographer to the mountain masses which extend more towards the east, between the districts of Melitene and Commagene, and are prolonged across the Euphrates into Armenia, where they are connected with the more lofty ranges and high tablelands of that country. All this mountain region is still very imperfectly known, and it will require much investigation before its orographical relations are fully understood; but it is clear that there is such a mountain mass as that supposed by Strabo, and which may be regarded as continuous, though cut through by deep and narrow gorges, through which the rivers Sarus and Pyramus force their way from the elevated valley of Cataonia to the low plains of Cilicia. Just in the same manner th Euphrates, further east, forces its way through the same mountain range by a channel so narrow and tortuous as to afford no means of communication, so that travellers proceeding south from Malatiyeh (Melitene) to Samosata on the Euphrates, have to cross a pass over the mountains known as the pass of Erkenek. The range here traversed, which is of very considerable elevation, appears to be continuous with that which forms the boundary of Commagene on the west, and is continued under the name of Mount Amanus to the Gulf of Issus. Strabo is also certainly correct in regarding it as connected with the mountains of Armenia, but these lie beyond the limits which we are at present considering.

At a short distance from the chain of the Taurus and Anti-Taurus to the west, but wholly unconnected with them geologically or in a true geographical sense, is a remarkable series of volcanic peaks or groups, extending in a direction from N E. to S.W., through an extent of more than 150 miles. The northernmost and most elevated of these was known to the ancients as Mount Argæus, and is still called by the Turks Erdjish-dagh. It is the highest mountain in Asia Minor, attaining to very nearly (if it does not exceed) 13,000 feet, and its base is upwards of 60 miles in circumference. About 60 miles S.W. of this rises the volcanic mass of Hassan-dagh, the highest peak of which attains an elevation of above 8000 feet, and which has covered the whole country to the north-east with a vast extent of volcanic deposits. Beyond this, towards the S.W., is situated the volcanic group of Karadja-dagh, of very inferior altitude, but interesting as exhibiting a well-marked series of volcanic cones, having in some instances very well preserved craters, extending through a range of above 35 miles, as far as the village of Kara Bounar. About 25 miles S.W. of this rises the insulated mass of Kara-dagh, of similar volcanic character, and estimated to attain to a height of about 8000 feet. All these volcanic mountains are composed principally of trachyte, and though separated by intervening spaces, either of level plain or gently undulating country, may be regarded as forming part of the same line of volcanic action, the axis of which has a direction nearly from N.E. to S.W. It is remarkable that this is almost precisely parallel with the line of the Anti-Taurus, as formed by the Ala-dagh and its continuation towards the north.

Nearly at right angles with the series just described is the range called the Sultan-dagh, which extends through a space of more than 120 miles from the neighbourhood of Afiom Kara Hissar to that of Konieh. It has a general direction from W.N.W. to E.S.E., and is separated from the neighbouring portions of the Taurus by a broad valley having an average elevation of over 3000 feet, as well as by the three upland lakes of Egerdir, Kereli, and Soghla Its central and highest portion rises to more than 6000 feet in height, and forms a continuous barrier between the valley above described and that known to the ancients as Phrygia Paroreios, through which lay the high road from the central plain of Phrygia to Iconium and the passes of the Taurus. Nearly parallel with the chain of the Sultan-dagh, and of about equal altitude, is that now known as the Emir-dagh, which forms the boundary of Phrygia Paroreios on the north, separating it from the great open plains of Galatia and Lycaonia, the latter of which extend without interruption to the great salt lake of Tatta.

We now come to consider the numerous mountain chains that branch off from the borders of the great central plateau to the west, and descend to the shores of the Ægean, leaving between them valleys of surpassing beauty and fertility, which were in ancient times thickly studded with towns and cities of Greek origin. As these valleys widen out in approaching the sea, the mountain chains that separate them become clearly marked, and can be readily distinguished; but as we attempt to trace them back towards the interior, it will be found that they often arise in the same knot or cluster of mountain masses, and are in fact only branches radiating from the same point. But as there is no great central chain from which they can be regarded as emanating, it is convenient to describe them separately,—the more so as, from the familiarity of the Greek writers with this portion of Asia Minor, almost every range has some distinctive appellation by which it is well known to scholars.

It has been already shown that there is no natural limit between the ranges that form the termination of the chain of Taurus on the west, and those that branch off to the Ægean through Caria. The lofty range of Baba-dagh (known to the ancients as Mount Cadmus) in the interior, on the confines of Phrygia and Caria, is certainly closely connected with the mountains that separate Lycia from the upland valley of the Cibyratis, as well as with the high range now called Boz-dagh (the ancient Salbacum), which descends in a S.W. direction, and forms the boundary between the Cibyratis and Caria. The lower ranges that spread out from thence through the province of Caria, known in ancient times by the appellations of Lida, Grium, and Latmus, may be regarded as only offshoots of this central mass. The ridge of Latmus is, however, in great measure detached, and may be considered as beginning on the south bank of the Mæander, and terminating towards the S.E. in the elevated plain or plâteau on which stand the ruins of Stratonicea.

The mountain ranges north of the Mæander are more clearly marked. That which Strabo describes under the name of Messogis arises on the borders of the great central table-land in the neighbourhood of the town of Buladun, and stretches from thence nearly due west for about 75 miles, till it approaches the neighbourhood of Ephesus, where it makes a sudden turn to the S.W., and ends in the bold mountain range and promontory of Mycale (now called Samsoun-dagh), just opposite to the island of Samos. It nowhere rises to any great elevation, but forms a continuous barrier (from 3000 to 4000 feet in height) on the N. side of the valley of the Mæander, which it separates from the parallel valley of the Cayster Beyond this latter again rises the chain of Mount Tmolus, now known as Boz-dagh, which branches off from Mount Messogis near the point of their common origin, and after sweeping round the sources of the Cayster, holds a course towards the west, till it sinks to the sea in the neighbourhood of Smyrna. Through the greater part of its range it forms the southern boundary of the valley of the Hermus, but near its western extremity there arises a subordinate range of inferior importance and elevation, which separates it from the course of that river. It is this inferior range, which is a mere offshoot of Mount Tmolus, of very little importance in a geographical point of view, that bore in ancient times the name of Sipylus, so celebrated from its connection with the fables of Tantalus and Niobe.

North of the valley of the Hermus arise a succession of ranges of no great elevation or importance, which separate it from the valley of the Caïcus, and that again from the Gulf of Adramyttium. All these masses, constituting a very broken and irregular country, may be regarded as connected in an orographical point of view with the interior range of the Demirdji-dagh, which extends through the whole of Mysia from near the Gulf of Adramyttium to the frontiers of Phrygia. It is apparently the Mount Temnus of Strabo, and is connected at its S.E. extremity with the more lofty groups called Ak-dagh and Murad-dagh, which rise out of the elevated plains of Phrygia to a height of about 8000 feet. The last of these mountains contains the sources of the Hermus, and the chain thus described forms the boundary separating that river, and the other streams which flow to the Ægean, from the Macestus and Rhyndacus, which flow northwards into the Sea of Marmora.

The north-western angle of Asia Minor, bounded by a line drawn from the Gulf of Adramyttium to the mouth of the Æsepus, so as nearly to coincide with the limits of the district known in ancient times as the Troad, is occupied almost entirely by the mountain system of which Mount Ida constitutes the centre. The highest summit—the ancient Gargarus, now known to the Turks as Kaz-dagh—rises to a height of 5750 feet, and sends out its arms and underfalls in all directions: the most lofty ridge being that which extends westward to Cape Lectum, while subordinate ranges fill up the space that spreads northwards to the Dardanelles and the Sea of Marmora.

Almost the whole of the northern provinces of Asia Minor, extending along the coast of the Black Sea—Bithynia, Paphlagonia, and Pontus—are extremely mountainous, and occupied through the greater part of their extent by successive ranges of mountains, filling up the space between the sea-coast and the borders of the great table-land of the interior. In a general view these may be characterised as forming a series of vast undulations, more or less parallel with the line of coast, which preserves a general direction from west to east. But when examined more in detail, they will be found to be complicated and broken in a manner that renders their description very difficult, while few of them have any historical importance or special geographical interest. It will suffice here to mention a few of the most important.

The most westerly of these ranges is that known as the Mysian Olympus, which rises on the borders of Mysia and Bithynia, immediately south of the city of Broussa, and extends in a direction from N.W. to S.E., between the valley of the Rhyndacus and the head-waters of the Gallus, one of the principal tributaries of the Sangarius. It attains a height of about 6400 feet, and is a conspicuous object in the view from Constantinople, as well as from the plains of the interior. After a range of about 60 miles it sinks to a comparatively low level, where it joins the table-land of Phrygia, but may be considered as continued by subordinate masses which connect it with the range of Demirdji-dagh on the one side, while other elevations branch off from it to the valley of the Sangarius, which separates it from the chain of Ala-dagh, sometimes known as the Galatian Olympus. This is a lofty range which extends pretty continuously from the valley of the Sangarius to that of the Halys, constituting during a considerable part of its course the frontier between Galatia and Paphlagonia. The highest and central portion of the chain rises to between 6000 and 7000 feet, and almost the whole province of Paphlagonia is filled up with the subordinate ranges and offshoots that may be considered as connected with it. From thence it is continued under the name of Kuseh-dagh, quite to the left bank of the Kizil Irmak or Halys. That river is indeed, in one part of its course, so closely hemmed in between two opposite ranges of mountains as to afford no passage for a road.

East of the Halys, again, the central and maritime portions of Pontus are traversed by a succession of mountain ranges, for the most part of no great elevation, but rising progressively as they approach to the great table-land of the interior. Throughout the whole line of coast, from near Samsoun (Amisus) to Trebizond, these mountains descend so close to the sea as to render the coast line extremely picturesque and varied. But the most important range appears to be that which extends from the neighbourhood of Trebizond, where it attains to an elevation of more than 8000 feet, in a direction towards W.S.W., so as to pass between the towns of Tokat and Sivas. It is here called Chamla Bel, and the passes by which it is crossed from one of these towns to the other attain to above 5000 feet. It is apparently this range to which Strabo gives the name of Paryadres, and which he describes as continuous with another mountain chain called Scydises, and connected also with the mountains of the Moschians, which occupied the sea-coast from Trebizond to the borders of Colchis. But though the great geographer was himself a native of Amasia, his ideas of the orography of his native country were apparently very vague, and he certainly has not supplied us with any definite ideas on the subject, while in modern times the region has still been very imperfectly explored. The whole tract on the borders of Pontus and Armenia is very rugged and mountainous, and is still, as in the days of Strabo, inhabited by wild and lawless tribes, which render it very difficult of access to strangers.

Rivers.—The rivers of Asia Minor are of very little importance in comparison with those of countries of similar extent in Europe. This is owing principally to the existence of the great table-land in the interior, the climate of which is remarkably dry, and a considerable part of which, as has already been pointed out, does not discharge its waters to the sea. The much steeper inclination of the river-beds, resulting from the high elevation of their sources, tends, moreover, to give them the character of mere torrents, rather than of placid and navigable streams, while at the same time none of them are fed, like the Rhine and the Rhone, by the unfailing supply of glaciers. The want of navigable rivers is, indeed, one of the great defects of the country, and one which, so far as the interior is concerned, must always remain a disadvantage not to be surmounted.

Much the largest river of the peninsula is the Halys, called by the Turks the Kizil Irmak, or "Red River," which derives additional interest from its having formed in early ages the boundary between the kingdoms of Lydia and Persia. It takes its rise in the mountains on the borders of Cappadocia and Pontus, in the district called by Strabo Camisene, about 70 miles above the modern town of Sivas, and flows in a direction nearly S.W. for above 200 miles, till it passes within 20 miles of the city of Kaisariyeh; soon after which it turns to the N.W., and then makes a vast bend round till it assumes a north-easterly direction, which it pursues as far as the town of Osmandjik. Here it makes a sharp and sudden turn, caused by its encountering the range of mountains which extends from Paphlagonia into Pontus, and which it traverses by a winding course through narrow gorges, between precipitous cliffs, until it emerges into the level country near the sea, which it enters about half way between Amisus (Samsoun) and Sinope. Its whole course (as measured on the map, without taking account of the minor windings) is not less than 560 miles, though, from its describing so great a curve, the direct distance from its sources to its mouth is only about 180 miles. In length of course, therefore, it is about equal to such rivers as the Elbe and the Loire, but it is far inferior to them in body of water, in which respect it scarcely equals the second class rivers of France. Even in the lower part of its course its breadth frequently does not exceed 100 yards.

The Halys has but few tributaries of importance. The most considerable are—the Delidji Tchai, which traverses the great upland plains of Galatia, and after flowing near the town of Yuzgat, joins the Kizil Irmak about 70 miles above Osmandjik; (2), the Gök Irmak ("Blue River"), which rises in the mountains of Paphlagonia, a short distance above the town of Kastamuni, and flows through a deep and narrow valley till it joins the Kizil Irmak in the midst of the narrow gorges above described.

At a short distance east of the mouth of the Halys is that of another of the most considerable streams that fall into the Black Sea—the Iris of ancient geographers, now known as the Yeschil Irmak, or "Green River." This has its source in the same range of mountains as the Halys, but flows from thence towards the N.W. It passes within a short distance of the town of Tokat, and under the walls of Amasia, the birth-place of Strabo, near which it bends abruptly to the N.E., as far as the site of the ancient Eupatoria, where it receives a tributary stream from the E., and thence pursues a course nearly due north for about 40 miles, till it enters the Black Sea about 15 miles east of Samsoun. It has a course altogether of about 200 miles. Its most important tributary is the one above noticed, the Lycus of Strabo, now called the Ghermeli Tchai, which is nearly equal to the main stream. It rises in the mountains on the borders of Armenia, nearly due S. of Trebizond, and flows under the walls of Niksar (the ancient Neo-Cæsarea). But great part of its course is still very imperfectly known.

The most important of the northern rivers of Asia Minor, after the Halys, is the Sangarius, which still retains its ancient name in the corrupted form of Sakaria. It falls into the Black Sea, W. of Heraclea, about 80 miles from the mouth of the Bosphorus. It has its sources in the uplands of Phrygia, not far to the N. of Afiom Kara Hissar, and flows by a very winding course through the great table-land of Galatia, as far as a place called Bei Bazar, about 50 miles W. of Angora, where it turns abruptly to the west, and traverses the mountainous regions of Phrygia and Bithynia, till, after approaching within a short distance of the Sea of Marmora, it again turns to the N.E., and pursues its course to the Black Sea. Its course has a length of more than 320 miles, while its sources, which are situated almost due south of its mouth, are distant from it only about 160 miles. Its two chief tributaries are the Enguri Su, or river of Angora, which flows past the city of that name, and the Pursak (the Thymbres of ancient writers), which passes near the towns of Kiutahia (Cotiæum) and Eski Shehr (Dorylæum), and falls into the Sakaria about 20 miles below the latter place.

The most considerable rivers which have their outlet to the Sea of Marmora are the Rhyndacus and Macestus, which unite their waters at a distance of about 15 miles from the sea. They both take their rise in the range of mountains known as the Demirdji-dagh, the Macestus having its source in a small lake called the Simau Göl, a few miles north of Simau (Synnaus), the Rhyndacus in the neighbourhood of Æzani, about 25 miles further east. They flow at first in widely divergent directions, but ultimately both turn towards the north; and the Rhyndacus (now called Adranas Tchai), which is the most considerable of the two, after forming the Lake of Apollonia (an extensive sheet of water), receives the waters of the Macestus a few miles lower down.

The streams which flow from the mountain mass of the Ida are of little importance in a geographical point of view, but two of them are of the highest interest from historical associations—the Granicus, so celebrated for Alexander's first victory over the Persians, and the still more famous Scamander, which flowed beneath the walls of Troy The first of these rivers rises in the northern slopes of Mount Ida, and flows northwards to the Sea of Marmora, after a course of little more than 40 miles. It is now called the Khodja Tchai, but it is a very inconsiderable stream. The Scamander has its sources in Kaz-dagh, the highest part of Ida (Mount Gargarus), and flows at first towards the west, but then turning northwards, pours its waters into the Dardanelles, near the point of Kum Kaleh, which marks the entrance into that remarkable strait.

The western portion of Asia Minor, between the Gulf of Adramyttium and the frontiers of Caria, is traversed by four considerable streams, which flow through parallel valleys from the uplands of the interior to the Ægean Sea. The most northern of these is the Caicus, now called the Bakyr Tchai, which rises in the chain of the Demirdji-dagh (Mount Temnus), and flows through the whole of Mysia, passing within about 5 miles of the city of Pergamus, and falling into the sea about 20 miles below that city, between the sites of Pitane and Elæa. Much more important, as well as more celebrated, is the Hermus, now known as the Ghediz Tchai, from the town of Ghediz, the ancient Cadi, in Phrygia, near its sources. These are derived from the two mountain masses called Ak-dagh and Morad-dagh, the latter being the more considerable stream. After their junction the river flows in a S.W. direction for about 30 miles, and then turns due west; it traverses the volcanic district of the Katakekaumene, and emerges below Adala into the broad and fertile valley, through which it continues to flow to the sea. It passes only about 5 miles to the north of the celebrated city of Sardis, and almost close to that of Magnesia. It appears to have in ancient times pursued its westerly course to the sea, which it entered near Phocæa; but at the present day it makes a turn abruptly to the S., and enters the Gulf of Smyrna about 10 miles from that city. Its only important tributary is the Hyllus, called also the Phrygius, which joins it at Magnesia from the N.E., having its sources above Thyatira. The Pactolus, so famous for its golden sands, which flows under the walls of Sardis, is a very trifling stream.

Next in order, proceeding south, comes the Cayster, a stream very inferior in magnitude to the Hermus and Mæander, which rises in the knot of mountains at the junction of Mount Messogis and Tmolus, and flows through a broad, fertile valley for above 70 miles, till it enters the sea just below Ephesus. It is now called the Kutschuk Mender or Little Mæander. The true Mæander (now called Bojûk Mender, or Great Mæander) is much the most considerable of the four rivers. It takes its rise at Apamea (previously called Celænæ) in Phrygia, above 175 miles in a direct line from its mouth, and is derived from abundant sources of water, so as to form a deep and clear stream almost immediately below its origin. Thence it flows for some distance to the N.W. as far as the site of Peltæ, where it receives a tributary called the Sandukli Tchai (the ancient Obrimas), sometimes erroneously regarded as the main stream, and there, turning to the S.W., pursues a course a little to the southward of west to the sea. It preserves this general direction with no great change, the numerous windings for which it was famous in antiquity being of no great magnitude or extent, but after passing through a series of mountain gorges between Peltæ and Tripolis, it emerges into a broad and rich alluvial valley, through which it holds its winding course to the sea. This valley is bounded immediately on the north by the lofty range of Mount Messogis, the streams descending from which have only a very short course, and the Mæander, in consequence, receives no affluents of any importance from this side. From the south, on the contrary, it receives several considerable tributaries, which have their sources in the mountains of Caria. The most important of these are the Tchoruk Su, which flows by Colossæ and Laodicea, the Arpas Su (the ancient Harpasa), and the Tchinar Tchai (the Marsyas of ancient writers), which rises in the mountain mass of Boz dagh, on the confines of Caria and Lycia, and flows by the site of Alabanda at Arab Hissar. The total course of the Mæander is estimated at about 240 miles.

All these rivers which we have just been considering are remarkable for the great amount of alluvial matter which they bring down, and the extensive deposits which they in consequence form where they enter the sea. Thus the Cayster, though the least considerable of the four, has not only filled up the port of Ephesus, but has pushed forward the shore for more than two miles beyond its site. The Mæander has blocked up the deep gulf formerly extending inwards from near Miletus to the foot of Mount Latmus, so as to convert the inner portion of the gulf into a lake, while it has entirely filled up the port of Miletus, united the island of Lade with the mainland, and formed a broad space of alluvial marshes extending thence to the foot of Mount Mycale. At the present day the alluvial deposits are advancing with such rapidity in the Gulf of Smyrna as to threaten Smyrna with the same fate as has befallen Miletus.

Of the rivers of Lycia the only one which deserves notice is the Xanthus, which rises in Mount Taurus, and falls into the sea about 12 miles below the city of the same name. But a much more considerable stream is that now known as the Gerenis Tchai, which rises on the northern side of Mount Taurus, at a short distance from the sources of the Xanthus, and flows in a northerly direction through the upland district of Cibyra, then turns suddenly round, and pursues a course about S.S.W., traversing the whole of the mountain region on the borders of Caria and Lycia, until it falls into the sea between Caunus in Caria and the Gulf of Macri. It was called Calbis in the lower part of its course, and Indus in the upper, but ancient geographers were apparently not aware that the two were in fact the same river.

The rivers which flow from the main chain of Taurus to the Mediterranean are very numerous, and many of them in winter bring down a large body of water. But they have necessarily but short courses, and few of them have much geographical importance. Of those which traverse the plain of Pamphylia it will be sufficient to mention the Cestrus and the Eurymedon, both of them considerable streams, pursuing parallel courses to the sea, which they enter within less than 20 miles of one another. The one flows beneath the ruins of Perge, the other by those of Selge and Aspendus. The rugged and mountainous country of Cilicia, which adjoins Pamphylia on the east, is furrowed by numerous streams flowing through deep and narrow valleys, the largest of which is the Calycadnus (now called the Gök Su, or "Blue River"), which has a direction nearly from W. to E., taking its rise in a lofty spur of Mount Taurus that advances close to the sea, so that its sources are not more than about 20 miles from the sea at Alaja, while it has a course of more than 100 miles (in a direct line) from thence to its mouth. It falls into the sea about 12 miles below Seleucia (still called Selevke), and is a deep and rapid stream of considerable magnitude.

The broad alluvial plain which forms the eastern portion of Cilicia is traversed by several rivers, two of which, the Sarus and Pyramus, now known as the Sihun and Jihun, are among the most important rivers of Asia Minor. Both of them alike take their rise far in the interior, in the high lands beyond the Taurus, and force their way across that great chain through deep and narrow gorges. The Sarus is indeed formed by the junction of two branches, both of which descend from the ranges of the Anti-Taurus through two parallel valleys, and after traversing for a long distance the mountain gorges, pour their united waters into the plain about 20 miles above the town of Adana. The Pyramus takes its rise in the upland district called Cataonia, near the modern town of Albistan, flows by Marasch, where it receives a considerable tributary from the east, bringing with it the waters of some small lakes on the reverse of the mountains of Commagene, and after passing near the ruins of Anazarbus, falls into the Gulf of Issus or

Scanderoon. Both these rivers have formed great alluvial deposits at their mouths, and it is probable that they have repeatedly altered their channels in flowing through the plain. Hence the accounts of them found in ancient authors are very contradictory. The Cydnus, which flowed by Tarsus, is a very inferior stream to those just described, though its name is perhaps better known than either of them. It rises in the mass of Mount Taurus called the Bulghar-dagh, and has a course of not more than 50 miles to the sea, but is a clear and rapid river.

Lakes.—The lakes of Asia Minor are numerous, but of no great importance. The most extensive is the great salt lake already noticed, on the borders of Lycaonia and Cappadocia, which is bounded on the east by a considerable range of mountains called Khodja-dagh, while on the west it is separated only by some low hills from the broad upland plains, or steppes, of Lycaonia. Beyond these to the west, but separated from them by the range of the Emir-dagh, is a string of three lakes of no great extent, having a general direction from N.W. to S.E., and following the line of the valley of Phrygia Paroreios. They bear the names of Eber Göl, Ak-Shehr Göl, and Ilgun Göl, and are all basins of fresh water passing into mere marshy pools during the dry season. Much more important than these are the two lakes now known as the Egerdir Göl and Kereli Göl (from towns of those names built upon their banks), which are situated between the range of the Sultan-dagh and the northern offshoots of the Taurus, and are both of them extensive mountain lakes of not less than 30 miles in length. The northernmost of the two (the Egerdir Göl, which is described as the most picturesque and beautiful of the lakes of Asia Minor) is situated at an elevation of about 2800 feet above the sea, while the level of the neighbouring Kereli Göl, which is separated from it by an intervening range of mountains, is at least 800 feet higher. Both are perfectly fresh, and their waters clear and deep, though the one has no outlet, and the other communicates only by a small rivulet with the much smaller lake called Soghla Göl, the waters of which occasionally disappear altogether. They are without doubt carried off by subterranean channels. About 30 miles S.W. of the Egerdir Göl is the Lake of Buldur, adjoining the town of that name, and at a short distance north of this lies the Tchoruk Su Gol, or Lake of Chardak, the waters of which are extremely salt, so that large quantities of salt are collected there, and sent from thence to Smyrna.

In the north western portion of Asia Minor, within the confines of Mysia and Bithynia, are situated three lakes of a wholly different character from the preceding, but havin much the same features in common. These are the Lake of Nicæa (still called Isnik Göl), the Lake of Apollonia (Aboulonia Gol), and the Lake of Miletopolis (Manyas Gol) All these are within a few miles of the Sea of Marmora, into which they discharge their waters. The Lake of Apollonia (which is rather the largest of the three) is formed principally by an expansion of the river Rhyndacus, which may be considered as flowing through it. The Lake of Nicæa, on the contrary (called also Lake Ascania), is a mere basin formed by the streams which descend from the surrounding mountains, and discharging its waters into the neighbouring Gulf of Moudania by a channel only about 10 miles long. The lake itself does not exceed 20 miles in length.

Climate and Natural Productions.—The climate of Asia Minor necessarily presents great differences. All travellers have remarked on the striking contrast as they passed from the warm and fertile regions of the west and south to the cold and bleak uplands of the interior. The great central plateau, which constitutes so large a part of the country, is not only much colder than regions in corresponding latitudes in Europe, but is characterised by a great dryness, in consequence of the moisture from the Mediterranean being in great part intercepted by the continuous mountain chain of the Taurus. The result of this, combined with its great elevation above the sea, is to render the summers excessively hot, and the winters extremely cold. In both these respects the climate of the central parts of Asia Minor presents a close analogy with that of Central Spain, as well as with the still more extreme case of the neighbouring Armenia. On the other hand, the plains and low valleys on the south coast, which are in a latitude corresponding to that of Sicily and the south of Spain, have a mean temperature considerably higher than those countries, and the summer heat at Tarsus is said greatly to exceed that of Cadiz or Gibraltar, and to be nearly equal to that of Cairo. Systematic observations for any length of time are, however, almost wholly wanting. The north coast, on the contrary, is subject to the depressing influence of the cold winds and fogs of the Euxine, which, as is well known, bring down the mean temperature of Constantinople (and still more its winter temperature) far below that of places in corresponding latitudes on the Mediterranean. This effect is, however, found to diminish as one proceeds eastward along the shores of the Euxine; and the climate of Trebizond, which is situated almost exactly in the same latitude with Constantinople, is much milder than that of the capital, or of the neighbouring city of Broussa,—a result, doubtless, produced by the sheltering action of the great range of the Caucasus, which prevents the cold winds from the steppes of Russia to the N. and N.E. from sweeping down on the eastern angle of the Black Sea. The western districts of Asia Minor are in all respects the most favoured, and the coasts of Ionia and Caria may be considered as enjoying one of the finest climates to be found in any part of the Mediterranean. The action of the cold north winds from Thrace and the Bosphorus is, however, still felt as far south as Smyrna, and the winters at that place are somewhat colder than those in corresponding latitudes in Spain and Sicily.

The vegetation of the different parts of the peninsula naturally varies with the climate and the soil. The southern coasts present most of the plants and shrubs characteristic of the southern portions of the Mediterranean, with the exception of the prickly pear and American aloe (both of them originally exotics imported into Europe), which form so important a feature in the landscape of Sicily and the south of Spain, as well as of Syria, but are very rare in Asia Minor, while the dwarf palm (*Chamærops humilis*) is wholly wanting. The date palm is occasionally found, but does not ripen its fruit even at Tarsus, where the summer temperature is almost tropical. The vegetation of Lycia, which occupies an intermediate position between the hot plains of Pamphylia and Cilicia and the comparatively temperate western provinces, is thus described by Forbes:—

"The wild olive covers the hills, wherever the pine (*Pinus maritima* and *halepensis*) and the arbutus leave room The valonea oaks (*Quercus Ballota, Ægilops*, and *infectoria*) afford ample shade. The mastic, the fig, and the mulberry are not unfrequent, both cultivated and wild. The Oriental planes afford abundant shade near every village; and the dark and towering cypress is planted by the place of burial, but grows wild in the ravines The pomegranate flourishes in great abundance, and its wild fruit supplies a grateful refreshment under the warm sun of autumn The almond and manna ash grow wild among the rocks, and the bay and Judas-tree in the ravines The orange and the lemon are cultivated. Melons, cucumbers, sesame, maize, cotton, capsicum, lentils, kidney-beans, and balmias (*Hibiscus esculentus*), are the common cultivated vegetables "—(Spratt and Forbes's *Lycia*, vol. ii. p. 152.)

Higher up on the mountain slopes and the uplands facing the sea is the chief realm of the oak and pine forests, with which a large part of the chain of Taurus is covered. The walnut is the most plentiful and conspicuous tree around the villages, while vineyards and tobacco fields yield rich produce. The high upland plains, on the contrary, are generally bare and treeless, but the villages are frequently surrounded with walnut trees, Lombardy poplars, apples, apricots, and willows. The vine is still grown in many spots in these elevated regions, though in others it will not thrive. Large tracts of the table-land of the interior, as has been already mentioned, are either quite barren and desolate, or open treeless downs, affording pasture only to sheep. But it is probable that they would be capable of producing abundant crops of corn (like the similar tracts of Central Spain) if properly cultivated, except in a few districts, such as the steppes of Lycaonia, where the soil is strongly impregnated with salt.

The northern coast districts present a wholly different climate, and from the influence of the Black Sea and the cold of Russia, have much more of the character of the temperate regions of Europe than of that of Rome or Naples which correspond to them in latitude. But the mountains are covered with extensive forests of oaks, chestnut, beech, box, and other trees, while the valleys produce fruit trees in extraordinary abundance and variety. This is the case especially in the province of Pontus, extending eastward from near Sinope to Trebizond, which is a country of singular beauty and great fertility, notwithstanding its mountainous character. This region is supposed to be the native land of many of our well-known fruits, especially cherries and apricots. The hills also are covered with medlars, apple, pear, and plum trees, all growing wild, but cultivated also with great success in the neighbourhood of the villages and towns. The olive also thrives in sheltered situations, though it is not found west of Sinope. At the same time, the luxuriant undergrowth of rhododendrons and azaleas, besides bay, myrtle, arbutus, and other flourishing shrubs, gives a special charm to the scenery of this beautiful region.

Among the vegetable productions that are of importance in a commercial point of view may be mentioned saffron, which is so largely cultivated at a town in Bithynia as to have given it the name of Safaranboli; opium, which has in like manner given name to Afiom Kara Hissar; madder, extensively grown at Ak Shehr; the orchis called salep; and cotton, of which considerable quantities are now produced in the warmer districts near the sea. Mulberries also are extensively cultivated, and large quantities of silk produced in the neighbourhood of Broussa, where there are now established large silk manufactories, as well as at Tokat, Amasia, and other places. The dried figs and raisins for which Smyrna is so celebrated are grown principally in the valley of the Mæander near Aidin.

The wild animals of Asia Minor are in general the same as are found in most parts of Europe, though a few mark its connection with the more eastern parts of Asia. Wolves, wild boars, bears, foxes, are abundant; but with them is associated the jackal, which is found in large troops in all parts of the country. The lion, which was certainly an inhabitant of Asia Minor in ancient times, is no longer found in any part of the peninsula, and though the tiger is said to exist in the Cilician Taurus, the fact does not rest on any good authority. But leopards still occur not unfrequently in the mountain country of the Taurus, and from thence range along the mountains to the west, so that they have been occasionally shot even in the neighbourhood of Smyrna. The high mountains are frequented by the ibex and chamois, while the true wild goat (*Capra Ægagrus*) is found on those of Cappadocia and Cilicia. The moufflon, also, is not uncommon in Cappadocia; but the wild ass, which existed there in the time of Strabo is no longer found within the limits of the peninsula The gazelle abounds in the plains of Cilicia, while both fallow and roe deer are found in the forests in large numbers. In regard to the domestic animals, the remark of Professor Forbes, that in Lycia the introduced camel and buffalo, both unknown to the country in ancient times, now play a more important part than the aboriginal quadrupeds, may be extended to the greater part of Asia Minor. Enormous numbers of sheep are, however, reared on the vast plains of the interior, as well as in the level parts of Cilicia, though they no longer retain the celebrity they enjoyed in antiquity for the fine quality of their wool. This, however, supplies the material for the celebrated Turkish carpets, the principal manufactory of which is at Ushak in Phrygia. Not less celebrated is the breed of goats peculiar to the neighbourhood of Angora, the hair of which is worked up into shawls but little inferior to those of Cashmere. No trace is found of the existence of any such peculiar race in ancient times, or even in the Middle Ages, and the period of its introduction is unknown. In comparison with the sheep and goats, cattle occupy but a subordinate position in Asia Minor; and though the plains of the interior, and still more those of Cilicia, were celebrated in ancient times for the number and beauty of the horses reared on them, nothing of the kind is now to be found, and the horses of Asia Minor are generally of an inferior description.

The geology of Asia Minor is still very imperfectly known, very few districts having been as yet examined in detail; but the researches of Hamilton, Ainsworth, and Tchihatcheff, and of Edward Forbes in Lycia, have thrown much light on the subject, and enabled us to form a general notion of the structure of the country. The great mass of the chain of Mount Taurus, and of the subsidiary ranges connected with it, consists, as has been already noticed, of the formation known as Apennine limestone, which is generally referred by geologists to the Cretaceous period. No sedimentary formations of older date are known to exist in the southern parts of the peninsula, but in the northern districts this is replaced by saccharine limestones and mica schists, with other metamorphic rocks, which are probably to be assigned to a much earlier period. The great table-land of the interior is composed for the most part of a vast lacustrine or fresh water formation belonging to the Tertiary period; and large portions of similar fresh water tertiaries, detached from the great central mass, are found scattered between its borders and the coasts, in some instances descending quite to the sea, as in the neighbourhood of Smyrna. But in the interior the lacustrine limestones and marls are frequently intermixed with extensive deposits of volcanic tuffs, the soft materials of which are rent by water-courses into deep and narrow glens, often studded with cones and pinnacles, presenting a great variety of picturesque and singular forms, and constituting one of the most peculiar features of the scenery of Asia Minor. Igneous rocks are found scattered through almost all parts of the peninsula, and the remarkable chain of volcanic mountains extending from Mount Argæus to the Kara-dagh near Karaman has been already noticed. All these mountains are of a trachytic character, and apparently belong to the Tertiary period; but there is a district on the borders of Phrygia and Lydia which presents volcanic phenomena of a much later date. It was known in ancient times as the Katakekaumene, or Burnt country, and its volcanic character was fully recognised by Strabo, though we may infer from his silence that there was no record of any eruption within the historical period. It has been fully described by Mr Hamilton, and presents three conical black hills of scoriæ and ashes, with well-defined craters, from which have flowed broad streams of rugged black vesicular lava, the surfaces of which are as barren and as little influenced by atmospheric action as the latest products of Vesuvius, so that if it were not for the negative evidence to the contrary, they might be well supposed to belong to a recent historical period. Igneous rocks of an older character are found in many parts of Asia Minor; those in Lycia are principally serpentine, while in the north-western districts various forms of trachyte prevail, and several of the minor ranges which rise out of the great central table-land are of granitic character.

Towards the sources of the River Halys is an extensive formation of saliferous red sandstones with gypsum, which would doubtless yield abundance of salt, were not that article more readily procured from the salt lakes already mentioned. Coal is found in the neighbourhood of Heraclea on the Black Sea, and was worked to some extent during the Crimean War. There is little doubt that Asia Minor is rich in minerals, but they are nowhere worked to much purpose. Iron ores of very good quality are still found in abundance in the country of the Chalybes, so celebrated among the Greeks for their skill as workers of iron, and they are still worked in a very primitive fashion by the inhabitants. The district of Cibyra, also, which was noted in the days of Strabo for its iron manufactories, still produces iron ores in plenty, of the same kind as those of Elba, but they are altogether neglected. The copper and silver mines of the north, though partially worked, are of very little importance. The same neglect has befallen the numerous quarries of marble, which attracted so much attention in the time of the Romans, and among which those of Proconnesus (the island of Marmora) and those near Synnada (Afiom Kara Hissar), producing the kind known as Phrygian marble, were the most celebrated.

Though Asia Minor had no active volcanoes it was subject in all ages to frequent and severe earthquakes. The most remarkable of these was one which occurred in 17 A.D., during the reign of Tiberius, and which almost entirely destroyed twelve considerable cities, including Magnesia and Sardis. Laodicea, also, was peculiarly subject to these visitations, which Strabo sagaciously connects with the evidences of recent volcanic action in the Katakekaumene. Thermal springs are found in many parts of the peninsula, but the most remarkable are those of Broussa, which from their proximity to Constantinople are still much frequented, and those at the ancient Hierapolis, the site of which is now utterly deserted.

Ancient Divisions and Ethnography.—The division of Asia Minor which is commonly adopted by geographers, and which is followed in the present article, is that given by Strabo, which coincides in the main with those of Ptolemy and Pliny. According to this the whole peninsula is considered as comprising—1. Pontus, on the Euxine, adjoining the frontiers of Armenia, and extending west as far as the Halys; 2. Paphlagonia, from the Halys to the Parthenius; 3. Bithynia, from the Parthenius to the Rhyndacus; 4. Mysia, which, with the subordinate districts of the Troad and Æolis, or the land occupied by the Æolian Greek colonists, comprised the north-western angle of the peninsula; 5. Lydia, of which Ionia in like manner formed the sea coast; 6. Caria, including the Dorian Greek colonies; 7. Lycia; 8. Pamphylia; 9. Cilicia—the last three provinces extending along the southern coast, from the Gulf of Macri to the frontiers of Syria; while in the interior were—10. Pisidia, comprising only the rugged mountain country above Pamphylia; 11. Phrygia, forming the western portion of the great table-land; 12. Galatia; 13. Cappadocia; 14. Lycaonia and Isauria, two barren and mountainous regions on the north side of Mount Taurus. (For farther particulars as to the extent and limits of these different regions the reader must be referred to the respective articles.)

The system thus adopted by Strabo, and which appears to have been already generally received in his time, was, properly speaking, merely a geographical one. It did not coincide with the political or administrative divisions of the country, either in his time or for at least three centuries earlier. Though some of the countries enumerated—as Bithynia and Cappadocia—had continued down to a late period to form independent sovereignties, the limits of which were well established, the greater part of the peninsula had undergone many fluctuations and changes, the different provinces passing at one time under the kings of Syria, at others under those of Pergamus, and being transferred by the Romans in an arbitrary manner from the rule of one potentate to another. And when the Romans had established their own dominion over the greater part of the peninsula, it was long before the division of it into provinces had assumed a definite and settled form. But the Roman province of Asia, as it existed from the days of Cicero to those of Strabo, may be regarded as comprising Mysia, Lydia, Caria, and Phrygia, but excluding Lycia, Pisidia, Galatia, and Bithynia, so that it contained much less than half of Asia Minor, with which it is sometimes erroneously supposed to have been identical.

The divisions of the country thus generally recognised were in fact (with one exception) ethnographical ones, or at least had been so originally. Herodotus, the earliest writer from whom we have any information on the subject, describes Asia within the Halys, as containing fifteen different races or nations, including the Greek settlers; and of these the Cilicians, Pamphylians, Lycians, Carians, Lydians, Mysians, Bithynians, Paphlagonians, and Phrygians undoubtedly then occupied the countries which long after retained their names. East of the Halys lay the Cappadocians, who in his time occupied the whole country from the frontiers of Cilicia to the Euxine. It was not till a later period that the northern portion of this extensive country came to be known and distinguished from the rest as Cappadocia on the Pontus, and eventually under the designation of Pontus alone. Galatia, on the other hand, derived its name from the Gauls, who established themselves in that country about two centuries B.C., and continued to retain their language and nationality down to a late period of the Roman empire. The Lycaonians, Isaurians, and Pisidians are not noticed by Herodotus; probably the names of these obscure mountain tribes had never yet reached the ears of the Greeks.

Our information concerning the origin and ethnographical relations of the nations that we thus find occupying the peninsula at the earliest period is very imperfect, and rests almost wholly on the vague statements of ancient authors, none of the nations in question, with the exception of the Lycians, having left any trace of their language. But according to the distinct and uniform assertion of ancient writers, the Bithynians were of Thracian origin, and identical with the people who were separated from them by the narrow strait of the Bosphorus—a statement in accordance with the natural probability of the case. The same probability may be alleged also in favour of the Thracian origin of the Mysians, which is asserted both by Herodotus and Strabo, though they would appear to have settled in the peninsula at a much earlier period than the Bithynians. Much less value can be attached to the traditions concerning the original connection between the Mysians, Lydians, Phrygians, and Carians, which would assign a common Thracian origin to all these nations. The Carians indeed were, according to the more prevalent opinion among the Greeks, later immigrants from Crete and the adjoining islands—a theory certainly not supported by internal probability. But there seem strong reasons for regarding the Carians, like their neighbours the Lycians, as a peculiar people, distinct from all who surrounded them. The Lycians, as already mentioned, are the only people of Asia Minor who have left us the means of judging of their ethnic affinities by the remains of their language. From these we learn that they were an Aryan race, apparently more nearly connected with the Persians than with the Greek or other Pelasgic races. But besides the Lycians, there existed within the province of Lycia a tribe called the Solymi, who were generally considered as of Syrian or Semitic origin. The fact does not appear in their case to rest upon any sufficient authority, but the connection of the Cilicians, who held so large a part of the south coast, with the Syrians and Phœnicians, may be considered as well established. All ancient writers, moreover, agree in describing the Cappadocians, who originally extended from Mount Taurus and the frontiers of Cilicia to the Euxine, as a Syrian race, so that they were at first called by the Greeks Leucosyri, or White Syrians, to distinguish them from their darker brethren farther south. Whether the mountain tribes of the Pisidians, Isaurians, and Lycaonians were connected with the Cappadocians or with the Phrygians, or to what other race they belonged, we have no information whatever.

The population of Asia Minor at the present day can hardly be said to retain any traces of the earlier nations that composed it, though, according to some writers, the Zeybeks,—a race presenting some marked peculiarities, who occupy the south-western corner of the peninsula—are the lineal representatives of the ancient Carians. They, however, speak only Turkish. The bulk of the population is composed of Turks, Greeks, and Armenians, among whom the Turks preponderate greatly in numbers, and (unlike what is the case in European Turkey) compose the mass of the agricultural and rural population, while the Greeks and Armenians are found principally in the towns, where almost all the trade is in their hands. But besides these elements, which constitute the fixed and permanent population of the peninsula, there is a considerable portion consisting of nomad and half nomad tribes, which are known under the names of Turcomans, Yourouks or Eurnques (the name is very variously written), and Kurds. The last of these are found principally in the eastern and south-eastern districts, the Turcomans in the north-eastern and central provinces, and the Yourouks in the west and south-west of the peninsula. They are all exclusively pastoral races, but the Turcomans have in general their villages in which they spend the winter months, wandering over the great plains of the interior with their flocks and herds during the summer months. The Yourouks, on the contrary, are a truly nomad race, dwelling all the year round in tents, and removing from place to place according to the season. Their tents are made of black goats' hair, and their principal covering is a heavy cloak of the same material. Besides large flocks of sheep and goats, they breed many camels, and one of their principal occupations is burning charcoal, in the course of which they do enormous injury to the forests. They are by no means limited to the wilder districts of the interior, but when the harvest is over descend into the rich plains and valleys near the coast, through which they wander almost without restraint, and their black tents are often to be seen within a few miles of Smyrna. Though distinguished at the present day by certain peculiarities from the Turcomans, the Yourouks are apparently of Turkish origin, and speak a Turkish dialect. The Kurds, on the contrary, who are merely a wandering offshoot of the race that occupies the great mountain tract called Kurdistan, extending from the borders of Cappadocia between Armenia and Mesopotamia into Persia, speak a wholly different language, and belong altogether to a different race. They are, however, confined to the border districts on the eastern frontier of Asia Minor, and to Cilicia, where the tribes that have their summer encampments in the neighbourhood of Cæsarea descend to pasture their flocks in the winter.

History.—It is remarkable that a country like Asia Minor, possessing such great natural advantages, and to a great extent so clearly limited by nature, can hardly be said to have any history of its own. It was never at any period united under one independent sovereign, but was always either divided among a number of minor potentates, or, as under the Roman, Byzantine, and Turkish rule, constituted merely a subordinate portion of a more extensive empire. Its western and northern shores were from a very early period occupied by Greek colonies, which gradually formed an almost unbroken chain of settlements along its coasts and islands from Rhodes to Trebizond. But these exercised comparatively little influence upon the nations of the interior; and the first historical event that can be considered as affecting the fortunes of the peninsula in general, was the rise of the Lydian monarchy, which attained to so great a predominance that for a short time Crœsus, the last monarch of the dynasty (560–546 B.C.), had subdued the whole of Asia Minor west of the Halys with the exception of Lycia. But having, unfortunately, engaged in war with Cyrus, king of Persia, he was entirely defeated, and his dominions conquered by the Persian monarch. From this time the whole of Asia Minor, from the frontiers of Syria to the Hellespont and the Bosphorus, continued for more than two centuries to form part of the Persian monarchy, until its overthrow by Alexander the Great, 333 B.C. It was during this period divided into satrapies, the boundaries of which were, however, very uncertain and fluctuating, like those of the Turkish governments in modern days. In the division of the Macedonian empire after the death of Alexander, Asia Minor became a chief object of contention among his generals, but was ultimately included in the dominions of Seleucus, and the greater part of the peninsula continued for a considerable period to be subject to the Seleucidan kings of Syria. A small independent monarchy had, however, been established at Pergamus, soon after 280 B.C., and when the Romans entered Asia, and defeated Antiochus III. at the battle of Magnesia (190 B.C.), they transferred a considerable part of his dominions to Eumenes, king of Pergamus, whose kingdom was thus extended to the Taurus. The monarchy of Pergamus thus constituted continued to subsist till after the death of Attalus III., when it was annexed to the Roman dominions under the name of the province of Asia (130 B.C.) Bithynia, however, still continued a separate kingdom, as did also Pontus, which for a short period rose under the great Mithridates to be a really formidable power. But after the defeat and death of Mithridates, in 63 B.C., the greater part of his kingdom, as well as that of Bithynia, was annexed to the Roman dominion; and though some petty dynasties were allowed to linger on till after the Roman empire, the whole of Asia Minor was virtually subject to Rome from the time of Augustus. There ensued a long period of tranquillity and prosperity under the Roman and Byzantine empires, during which it suffered less than almost any other part of the empire from the inroads and ravages of barbarians. Even after the rise of the Mahometan power, though Asia Minor was repeatedly traversed by the armies of the Arab conquerors, who twice laid siege to Constantinople, it was never permanently annexed to the dominion of the caliphs, like the adjoining provinces of Syria and Mesopotamia, and the whole country, as far as the passes of Mount Amanus, continued subject to the Byzantine empire, until it was overrun by the Seljukian Turks in 1074 A.D.

The conquest of Asia Minor by the Turks was not a mere passing inroad, but a permanent occupation of the country, in which they established themselves in such numbers that they have ever since formed the predominant element in the population, and have to a great extent supplanted or absorbed all the previously existing races. But the dynasty of the house of Seljuk, established by the first conqueror Soliman, who had fixed his capital at Nice, within 100 miles of Constantinople, did not long retain its undivided sovereignty, and its power was broken by the armies of the first Crusade (1097 A.D.), which took Nice, defeated the Turks in a great battle at Dorylæum, and then swept over the land almost without opposition, up to the very walls of Antioch. The Byzantine emperor recovered possession of the whole circuit of the coast, from Trebizond to the Syrian gates; and the Seljukian sultans of Roum, as they termed themselves, who had removed their capital to Iconium, in the heart of the interior, found themselves cut off from the sea on all sides. Their dominion was gradually broken up, and divided among a number of small independent chieftains, until the rise of the Ottoman dynasty at the commencement of the 14th century once more consolidated the power of the Turks in Asia. The history of Asia Minor from this period is inseparably connected with that of the Turkish empire, and will be given under the head of TURKEY. To the same article we must refer our readers for the modern division of the country and the present system of administration, as well as for such statistical information concerning its present state as it is possible to collect in the absence of all official or trustworthy authorities.

At the commencement of the present century our information concerning Asia Minor was extremely imperfect. The survey of the southern coast by Captain Beaufort (published in his *Karamania*, 4to, Lond. 1817), was the first contribution to a sound knowledge of any part of the country; and the work of Colonel Leake (*Journal of a Tour in Asia Minor*, 8vo, Lond. 1824), in which he embodied a careful review of all the information then existing, and applied it to the comparative geography of the peninsula, became the basis of all subsequent researches. Since then the labours of successive travellers have thrown a great deal of light upon the subject, and most parts of the peninsula have been visited and described, though the materials for a good map are still wanting, and there exists no satisfactory geographical or geological description of many parts of the country. For further information and details our readers may consult Arundel's *Visit to the Seven Churches*, 8vo, Lond. 1828, and his *Discoveries in Asia Minor*, 1834; Hamilton's *Researches in Asia Minor, Pontus, and Armenia*, 2 vols. 8vo, Lond. 1842; Fellows's *Excursion in Asia Minor*, Lond. 1839, and his *Discoveries in Lycia*, Lond. 1841; Ainsworth's *Travels in Asia Minor*, 2 vols., Lond. 1842; Spratt and Forbes's *Travels in Lycia*, 2 vols., Lond. 1847; Langlois's *Voyage dans la Cilicie*, 8vo, 1861; C. T. Newton, *Travels and Discoveries in the Levant*, 2 vols., Lond. 1867.

The work of M. Tchihatcheff (*Asie Mineure—Description Physique, Statistique, et Archéologique*, 3 vols., 8vo, Paris, 1853–60), the result of several years' explorations in different parts of the country, and the first attempt at a systematic description of Asia Minor, has unfortunately never been completed. The first volume (published in 1853) contains by far the best description that has yet appeared of the physical geography of the whole peninsula; the second and third are devoted to the meteorology, zoology, and botany; but those which should have contained the geology and the archæology have never been published. (E. H. B.)

Alphabetical Index.

ASKEW, or ASCUE, ANNE, one of the numerous sufferers for the cause of the Reformation in the reign of Henry VIII., was a lady of great worth and beauty, of a good family in Lincolnshire, and in correspondence with Queen Catherine Parr and the chief ladies of the court. At first a Roman Catholic, she had gradually become convinced of the falsity of transubstantiation; and her husband, irritated at her change of religious opinions, compelled her to leave his house. On coming to London to seek for a divorce she was arrested, and interrogated by Chancellor Wriothesley and Bishop Bonner, at the instigation of whom, under threats of torture, she signed a qualified recantation. She was imprisoned, and wrote to the king, says Hume, "that as to the Lord's Supper she believed as much as Christ himself had said of it, and as much of His divine doctrine as the Catholic church had required." But while she could not be brought to acknowledge the king's explications, this declaration availed her nothing, and was rather regarded as a fresh insult. She was cruelly racked in the presence, and it was said by the hand, of the chancellor himself, in order to extort confession of those ladies about court with whom she corresponded. Her fortitude and fidelity probably saved the lives of the queen and others. She disclosed nothing, although her limbs were so dislocated by the rack that, when condemned to be burnt alive she could not stand, and was carried in a chair to Smithfield, where on 16th July 1546, she and four others underwent this terrible mode of execution with undaunted courage.

ASMAI or ASMAYI (full name, ABU SAÏD ABD-EL-MELEK IBN KORAÏB EL-ASMAÏ), is one of the most important representatives of Arabic literature in the 8th century of the Christian era. He was born at Basra 740 or 741 A.D, and attained, by his extensive erudition, to the high rank of preceptor to Harun al-Rashid, whose court was in that generation the great focus of intellectual activity in the East. Asmai was, as has been happily remarked by Barbier de Meynard, the almost perfect type of those nomadic devotees of literature who, after they had grown pale on the benches of Basra or Kufa, went to complete their education in the desert, in possession of boundless stores of learning, and yet animated by an enthusiasm for further acquisition, which made them willing to travel across the sands for hundreds of leagues, if only they might preserve an ancient tradition or pick up the fragments of an ancient song. Of the results of his labours he was no niggard, and a long list might be drawn up of his various productions. It is sufficient, however, to mention his synchronous history of the kings of Persia and Arabia previous to Islam—a work which Sir Henry Rawlinson has described as "perhaps the most valuable and authentic historic volume in the whole range of Arabian literature"—and his wonderful romance of *Antar*, which might almost be called the *Iliad* of the desert. He attained a good old age, dying, as is generally supposed, about 830 A.D., and left behind him a number of pupils, such as Thâlab, Ibn-el-Anberi, and Sukkari, who proved themselves worthy of their master.

ASMODEUS or ASCHMEDAI, an evil demon who appears in later Jewish tradition, and concerning whom there has been much vague and fanciful speculation. The name, probably, means the destroying angel or the tempter, but the etymological grounds for neither of these are quite certain. He is sometimes called the prince of demons, and identified with Beelzebub, but there are many other fables regarding his origin. In the apocryphal book of *Tobit* occurs the well-known story of his love for Sara, the beautiful daughter of Raguel, whose seven husbands were slain in succession by him on their respective bridal nights. At last Tobias, by burning the heart and liver of a fish, drove off the demon, who fled to Egypt. From the part played by Asmodeus in this story, he has been often familiarly called the genius of matrimonial unhappiness or jealousy. Le Sage makes him the principal character in his novel *Le Diable Boiteux*.

ASMONEUS, or ASSAMONEUS, the first of the dynasty or family of the Asmoneans, who ruled over the Jews for about 130 years. His great-grandson was the celebrated Mattathias (died 167 B.C.), the first of the Maccabees; and the direct line of princes descended from him was closed in 37 B.C. by the execution of Antigonus. Agrippa Herodes I. and II. were connected with the Asmoneans through their ancestress, Mariamne, wife of Herod the Great.

ASOLO, the ancient *Acelum*, a fortified town of Northern Italy, in the province of Treviso, about 19 miles distant from the city of that name. It is built in a beautiful and healthy situation, and possesses a cathedral and the ruins of a Roman aqueduct. In the neighbourhood is the former palace of Catharine Cornaro, queen of Cyprus, now turned into a dairy. Not far off is the quarry of Rocca. Population, 5437.

ASP (*Vipera aspis*), a species of venomous snake, closely allied to the common adder of this country, which it represents throughout the southern parts of Europe, being specially abundant in the region of the Alps. The term "Asp" (ἀσπίς) seems to have been employed by Greek and Roman writers, and by writers generally down to comparatively recent times, to designate more than one species of serpent, thus the asp, by means of which Cleopatra is said to have ended her life, and so avoided the disgrace of entering Rome a captive, is now generally supposed to have been the cerastes, or horned viper (*Vipera Hasselquistii*), of Northern Africa, a snake about fifteen inches long, exceedingly venomous, and provided with curious horn-like protuberances over each eye, which give it a decidedly sinister appearance. The species, however, to which the word "asp" has been most commonly applied, is undoubtedly the haje (*Naja haje*) of Egypt, a poisonous snake, from three to four feet long, with the skin of its neck loose, so as to render it dilatable at the will of the animal, as in the cobra di capello of India, a species from which it differs only in the absence of the spectacle-like mark on the back of the neck. Like the cobra, also, the haje has its fangs extracted by the jugglers of the country, who afterwards train it to perform various tricks. The asp (*Pethen*, פֶּתֶן) is mentioned in various parts of the Old Testament. This name is twice translated "adder," but as nothing is told of it beyond its poisonous character and the intractability of its disposition, it is impossible accurately to determine the species which the sacred writers had in view.

ASPARAGUS. The young shoots of *Asparagus officinalis* (Nat. Ord. *Liliaceæ*) have from very remote times been in high repute as a culinary vegetable, owing to their delicate flavour and diuretic virtues. The plant grows wild on the south coast of England; and on the waste steppes of Russia it is so abundant that it is eaten by cattle like grass. In common with the marsh mallow and some other plants, it contains a chemical principle called asparagin, to which it owes its medicinal qualities. The roots of asparagus were formerly used as an aperient medicine, and the fruits were likewise employed as a diuretic. Under the name of Prussian asparagus, the spikes of an allied plant, *Ornithogalum pyrenaicum*, are used in some places.

ASPASIA, a beautiful *hetæra* of Athens, celebrated in history by her connection with Pericles, was a native of Miletus, and settled in Athens, following the example of her countrywoman, Thargelia, who had become very famous during the time of the Persian wars. Her beauty, but still more her remarkable accomplishments, gained for her an extraordinary reputation, which was increased after her association with Pericles, who, having divorced his wife, united himself to Aspasia as closely as was possible under Athenian law, according to which marriage with a barbarian was illegal and impossible. Much of the administration of Pericles has been ascribed to her eloquent instruction and political sagacity, and her enemies did not scruple to lay to her charge the Samian and Peloponnesian wars. Although this exaggerates her power, yet her talents must have been extraordinary, for she drew to her house the most noble and learned in Athens, who were willing to learn from her. Even Socrates was not exempt from her influence. The political supremacy of Pericles, which exposed him to many assaults, attracted enmity to Aspasia. She was accused of impiety and other base crimes, and would probably have been condemned, had not the judges been swayed by the tears and entreaties of Pericles himself. After the death of that statesman's two sons by his lawful wife, he procured the passing of a law, by which the children of irregular marriages might be rendered legitimate. His son by Aspasia was thus allowed to assume his father's name. After the death of Pericles, Aspasia is said to have formed a similar connection with one Lysicles, wealthy, but of ignoble birth, whom she raised by her instructions to a prominent place in the state. This episode is somewhat obscure, especially as Lysicles seems to have fallen in battle in 428, the year after the death of Pericles. Nothing further is known of the history of Aspasia.

ASPASIUS, a Peripatetic philosopher, and one of the most prolific commentators on Aristotle, flourished probably towards the close of the 1st century A.D., or perhaps during the reign of Antoninus Pius. His commentaries on the *Categories*, *De Interpretatione*, *De Sensu*, and other works of Aristotle, are frequently referred to by later writers, but have not come down to us. Certain commentaries on Plato, mentioned by Porphyry in his life of Plotinus, have also been lost. Commentaries on the 2d, 4th, 7th, and 8th books of the *Nicomachean Ethics*, which pass under his name, were printed along with those of Eustratius and others by Manutius at Venice in 1536. They were translated into Latin by Felicianus in 1541, and have been frequently republished. The authenticity of part, and even of the whole, of these ethical commentaries has been disputed, and recently some fragments of another commentary by Aspasius on the *Ethics* have been printed. See *Classic. Jour.*, vols. xxviii., xxix.

ASPASIUS, a celebrated rhetorician and sophist, was born at Ravenna, and flourished during the early part of the 3d century A.D. He was the son (or, according to Suidas, the scholar) of the rhetorician Demetrianus; and, after a careful training in all the branches of a rhetorician's art, began to teach at Rome. For many years he filled the chair of rhetoric which had been founded by Vespasian. He travelled extensively in the suite of the emperor, as whose secretary he acted for some time. His orations, which are praised for their style, have been lost.

ASPEN TREE, called also the trembling-leaved poplar (*Populus tremula*), is a native of Britain, and is found generally in moist places, sometimes at a considerable elevation, 1600 feet or more, in Scotland. It flowers in Britain in March and April. The name "trembling" is applied to it on account of the constant movement of the leaves even with a gentle breeze. This mobility depends on the leaves being suspended by leaf-stalks flattened laterally, and when subjected to a slight wind, by their friction on each other they give rise to a rustling sound. It is supposed that the mulberry trees (*Becaim*) mentioned in 1st Chronicles xiv. 14, 15, were really aspen trees. The wood of the tree is white, and is made use of by turners. In France sabots are made of it; and the charcoal made from the wood is used in the manufacture of gunpowder. The leaves are in some countries of Europe employed as food for cattle, sheep, and goats.

ASPENDUS (or, as the name appears on the more ancient coins, ESTFENDYS), a city of Pamphylia, in Asia Minor, situated on an isolated hill near the river Eurymedon (*Capri-su*) at the extremity of the plain of Perga. It was founded by a colony from Argos, five centuries before the Christian era, and attained to great prosperity, as is attested, not only by the statements of Greek and Roman writers, but also by the noble ruins that still occupy the site. Of these the most remarkable is the theatre, which is regarded as more perfect than any other in Asia Minor, requiring but little restoration to render it fit once more for its ancient use. In the first precinct there are twenty-one rows of seats, and in the second eighteen, nearly all of them entire. The date of the building is assigned by an inscription to the time of Antoninus and Lucius Verus. An aqueduct of magnificent proportions, built, like the theatre, of the silicious conglomerate of the neighbourhood, still stretches across the plain; and the ruins of an agora and other erections are found on the hill. That the city was rich in valuable statues is mentioned by Cicero, who rhetorically accuses Verus of having plundered it of them all. It only appears occasionally in ancient history, as when its inhabitants surprised and assassinated Thrasybulus, and again when they surrendered to Alexander; but the populousness of the place is proved by the fact that it was able to furnish 4000 hoplites.

ASPER, HANS, a Swiss painter, was born in 1499 at Zürich, where he died on the 21st March 1571. He wrought in a great variety of styles, but excelled chiefly in flower and fruit pieces, and in portrait painting. Many of his pictures have perished, but his style may be judged from the illustrations to Gessner's *Historia Animalium*, for which he is said to have furnished the designs, and from portraits of Zwingle and his daughter Regula Gwalter, which are preserved in the public library of Zürich. It has been usual to class Asper among the pupils and imitators of Holbein, but an inspection of his works is sufficient to show that this is a mistake. Though Asper was held in high reputation by his fellow-citizens, who elected him a member of the Great Council, and had a medal struck in his honour, he seems to have been frequently in embarrassed circumstances, and there is reason to believe that he died a pauper.

ASPHALT, or ASPHALTUM (ἄσφαλτος, Aristotle, *Bitumen*, Pliny), the German *Bergpech*, or mineral pitch, so called from the Lacus Asphaltites or Dead Sea, where it was found in ancient times, is a product of the decomposition of vegetable and animal substances. It is usually found of a black or brownish-black colour, externally not unlike coal, but it varies in consistency from a bright pitchy condition, with a sharp conchoidal fracture, to thick viscid masses of mineral tar. Asphalt melts at or a little below the boiling point of water, and it burns with a rather smoky flame. It is regarded as the ultimate result of a series of changes which take place, under certain conditions, in organised matter, producing—1st, naphtha; 2d, petroleum; 3d, mineral tar; and 4th, asphalt or hard bitumen. The whole of these substances merge into each other by insensible degrees, so that it is impossible to say at what point mineral tar ends and asphalt begins. Naphtha, which is the first of the series, is in some localities found flowing out of the earth as a clear, limpid, and colourless liquid. As such it is a mixture of hydrocarbons, some of which are very volatile and evaporate on exposure; it takes up oxygen from the air, becomes brown and thick, and in this condition it is called petroleum. A continuation of the same process of evaporation and oxidation gradually transforms the material into mineral tar, and still later into solid glassy asphalt. Asphalts are very variable in composition, and their proximate constituents have not been subjected to a thorough examination. Traces of naphtha or light oils are usually found in them, and they always contain a percentage of the heavier hydrocarbons not vaporisable below boiling point. Resins soluble in alcohol, and solids, some soluble in ether, and some resisting the solvent action of both ether and alcohol, are found in varying porportions. According to Dana "asphalt may consist of either—(1), unoxygenated, or (2), partly unoxygenated and partly oxygenated (the usual fact), or (3), solely of oxygenated hydrocarbons (very rarely, if ever, true in nature). The state of solidity is not proof that any part of the bitumen is oxygenated." Asphaltic deposits exist widely diffused throughout the world, more especially in tropical and sub-tropical regions. It is found in a state of great purity in the interstices of the older rocks, but its occurrence is not characteristic of any particular formation or period. The most remarkable deposit of asphalt exists in Trinidad, where it forms a lake 99 acres in extent, and of unknown depth, intersected with rivulets of water. At two or three places on the surface of the lake an emission of semi fluid tar may still be seen in progress, accompanied with an evolution of sulphuretted hydrogen. At these points the substance is still soft and viscid, but by exposure it gradually obtains the consistency of the rest of the mass. In addition to the lake deposit, asphalt occurs in the surrounding country—named La Brea, on account of this peculiarity—in detached patches, or in sheets of considerable size, at one point protruding into the sea, and pieces of asphalt are frequently cast up on the neighbouring shore. A considerable quantity of a fine asphalt is also derived from Cuba under the name "Chapapote," or Mexican asphalt; and from Caxatambo in Peru, a very pure variety of high lustre is exported. The asphalt of the Dead Sea is more a tradition than a reality, it being now found there in very small quantities; but the source of the supply of ancient Babylon, the fountains of Is, on a tributary of the Euphrates, still yields asphalt. It occurs in many localities throughout Europe, but not to any considerable extent. The following table gives the ultimate composition of specimens from several localities:—

	Carbon.	Hydrogen.	Oxygen.	Nitrogen	Ash.
Auvergne, France	77·64	7·86	8·35	1·02	5·13
Cuba	82·34	9·10	6·25	1·91	0·40
Caxatambo, Peru	88·66	9·69	1·65		

Of greater importance industrially than simple asphalt is asphalt stone,—a limestone impregnated with bituminous matter, which occurs in large quantities at several European localities. The most valuable deposits are in the Val de Travers, canton of Neufchatel; in the neighbourhood of Seyssel, department of Ain; at Bechelbronn in Alsace, Limmer near the city of Hanover, and Hölle in Ditmarschen; in Holstein, &c. These bituminous stones contain from 7 or 8 to about 20 per cent. of asphalt in their composition, that from Val de Travers being richest in bituminous matter and of most value in its industrial applications. The asphalt beds of the Val de Travers were first discovered and utilised by Eirinus, a Greek physician, in 1712, who recommended the material as being "peculiarly suitable for covering all kinds of constructions; to protect wood and stone work against decay, worms, and the ravages of time, rendering them almost indestructible even when exposed to wind, wet, and extreme variations of temperature." Eirinus was aware that asphaltic mortar had been used in the building of ancient Babylon, and he himself succeeded in using it with great effect for the lining of cisterns and walls as a cementing material, and for the flooring of warehouses, &c. After some time the material fell into disuse; the quarries of Val de Travers were even forgotten, and it was not till the year 1832 that the material was again prominently and successfully re-introduced, the credit on this occasion being due to the Count Sassenay. Under his direction asphaltic stone came to be extensively used in France for pavements and roadways, and for protecting floors and walls from the effects of damp. From France the application of the material for such purposes extended to other countries, and there is now a wide-spread demand for asphaltic pavements. Two principal methods are adopted in laying asphalt pavements,—1st, the mastic process; 2d, the hot compressed process. The mastic process is essentially as follows:—The bed of the road-way is prepared with a smooth level foundation of concrete, which must be thoroughly dry before the application of the asphalt. The mastic is prepared for application by heating the asphaltic stone and breaking it into small pieces, which are then melted up with a quantity of mineral tar, to which some sand is added. The molten mass is then poured over a section of the prepared concrete uniformly to the requisite depth; the surface is smoothed, and covered with a coating of fine sand which is stamped into the asphalt. The proportions of tar and sand used vary with the composition of the asphaltic stone employed and the position occupied by the pavement. The other mode of laying pavements, now extensively adopted, consists in spreading hot powdered asphaltic stone on the prepared surface, which is then heavily pressed till it forms a homogeneous elastic coating. Roadways so prepared are very durable, smooth, cleanly, and noiseless, but the material is not well adapted for other than level streets on account of the difficulty of foothold. Complaints are also made against such pavement, to the effect that accidents to horses from slipping and falling are much more frequent than is the case on ordinary stone pavement. An artificial asphalt is prepared by boiling up the pitch of gas-tar with chalk and sand, but such a substitute, though much cheaper, has not the durability of the natural compound. Gas-tar asphalt is also applied for other purposes in which the natural product is used. Asphalt was used by the ancient Egyptians in their process of embalming bodies. It is the principal ingredient in black Japan varnish. It is distilled in large quantities for the illuminating and lubricating oil which it yields, but the bituminous shales from which paraffin and paraffin oils are distilled must not be confounded with asphaltic deposits. It is also used for preparing roofing felts; paper water-proofed with asphalt has been used, and drain-pipes of compressed asphalted paper are manufactured.

ASPHYXIA (α priv., σφύξις, a pulse), a term in medicine which, though literally signifying loss of pulsation, is applied to describe the arrestment of the function of respiration from some hindrance to the entrance of air into the lungs. (See PHYSIOLOGY and MEDICAL JURISPRUDENCE.)

ASPINWALL, or COLON, a city and free port on the northern coast of Panama, one of the united states of Colombia. It is built on the well-wooded coral island of Manzanilla, in lat. 9° 22′ 53″ N., and long. 79° 52′ 58″ W., owes its origin to the Panama Railway Company, who founded it (1850) for the convenience of their traffic, and derives its more usual name from W. H. Aspinwall, one of their principal shareholders. In spite of the unhealthiness of its situation,—now, indeed, largely diminished,—and the dangerous winds from the north to which it is at some seasons exposed, it has quite superseded the neighbouring port of Chagres, and become the centre of a considerable local trade. The banana, especially, is cultivated in the neighbourhood and largely exported to New York. The population, composed mainly of Jamaica and Spanish negroes, was stated at 6500 in 1872. A telegraph line extends from Aspinwall to Kingston in Jamaica.

ASS, The DOMESTIC—*Asinus vulgaris*, Gray,—differs chiefly from the horse in its smaller size, in the presence of long hair, forming a tuft, only at the extremity of the tail; and in the absence of warts on its hind legs. Its fur, usually of a gray colour, is characteristically marked with a longitudinal dorsal streak of a darker hue, with a similar streak across the shoulders, but white and black varieties also occur. The ass has been from time immemorial under the dominion of man, and it is doubtful whether the original wild stock is anywhere to be found at the present day,—the specimens that have been described as wild being probably the descendants of individuals that have escaped from the domestic state. A wild variety of ass (*Asinus tæniopus*), found in Abyssinia, has the long acute ears and the bray peculiar to the domestic kinds. It is said also to have cross bands on its legs, a feature occasionally met with in our tame breeds; and this fact has led Darwin and others to conclude that, in the wild ass of Abyssinia the original of the domestic animal is to be found; the stripes which occasionally appear on the legs of the latter being regarded as instances of reversion to the ancestral type (*Proceedings of Zool. Society*, 1862). The marked aversion of the domestic ass to cross the smallest streamlet, an aversion which it shares with the camel, and the evident delight with which it rolls itself in the dust, seem to point to arid deserts as its original home. The ass has generally been the object of neglect and ill treatment; and attempts have seldom been made to improve the breed by selecting and matching the finer specimens. It has thus gradually sunk into the dull and obstinate creature which we are accustomed to see. Its reputation for stupidity is not, however, of recent origin. The ancient Egyptians hated it, and symbolised an ignorant person by the head and ears, and the Romans thought it a bad omen to meet an ass (Fosbrooke's *Antiquities*). In the Middle Ages the Germans of Westphalia made the ass the symbol of St Thomas, the unbelieving apostle; and the boy who was last to enter the school on St Thomas' day was called the "Ass Thomas" (Gubernatis's *Zoological Mythology*, vol. i. p. 362). That the ass possesses qualities, which, if developed by careful selection and humane treatment, would make it a worthy companion of the horse as the servant of man, is seen in the too rare instances in which it has received proper attention. In Southern Europe—especially in Spain, Italy, and Malta—the ass is carefully bred, and has thus been greatly improved. No less than £200, it is said, is sometimes paid in Spain for a stallion ass. In the state of Kentucky, where mules are in great request as beasts of burden, asses, imported from the south of Europe, are reared with scrupulous care, and with such success, that from an average height of fourteen hands the Kentuckians have raised these animals to fifteen and even sixteen hands. That the diminutive size of the ass in cold countries is due as much to neglect as to rigour of climate seems proved by the fact, that in the north of India, where it is used by the lowest castes, the ass does not attain a height greater than that of a Newfoundland dog. It is, however, among the south-western nations of Asia and in Egypt that the ass has received that attention usually bestowed in this country on the horse, and it is there that it is to be seen in greatest perfection. The Arabs and Persians know the pedigrees of their asses, and by careful selection and interbreeding they have formed and perpetuate many useful races. Thus in Syria, according to Darwin, there are four distinct breeds:—"a light and graceful animal with agreeable gait used by ladies, an Arab breed reserved exclusively for the saddle, a stouter animal used for ploughing and various purposes, and the large Damascus breed with peculiarly long body and ears."[1]

The ass, there is little doubt, was first domesticated in Asia,—probably prior to the domestication of the horse,—whence it passed at a comparatively late period into Europe, for in the time of Aristotle it was not found in Thrace. In England there is evidence of its presence so early as the time of the Saxon Ethelred, but it does not appear to have been common till after the time of Queen Elizabeth. The koulan, or wild ass (*Asinus Onager*, Gray), differs from the domestic species in its shorter and more rounded ears, and in the greater length and finer form of its limbs. Its fur shows the dark streak along the back, but the streak across the shoulders does not appear to be a constant character. It is chiefly to be met with in the plains of Mesopotamia, in Persia, in Cutch, on the shores of the Indus, and in the Panjab, congregating in herds under a leader, and migrating southwards on the approach of winter. The adults are exceedingly shy, so that it is difficult to get within rifle range of them. According to Layard, who had ample opportunity for observing them during his researches around Nineveh, "they equal the gazelle in fleetness, and to match them is a feat which only one or two of the most celebrated mares have been known to accomplish." In the same region, over 2000 years ago, Xenophon, during the famous expedition of Cyrus, observed herds of wild asses so "fleet that the horsemen could only take them by dividing themselves into relays, and succeeding one another in the chase." The young are sometimes caught during spring by the Arabs, who feed them with milk in their tents. They are hunted chiefly by the Arabs and Persians, by whom their flesh is esteemed a delicacy. Their food, according to Dr Shaw, consists mainly of saline or bitter and lactescent plants; they are also fond of salt or brackish water. The leather known as shagreen, from the Turkish term *sagri*, is made from the skin of the ass; the ingrained aspect which it bears is not, however, natural to it, but is produced by a chemical process described by Pallas. The milk of the ass, containing more sugar and less caseine than that of the cow, closely resembles woman's milk, and has long been valued as a nutritious diet where the digestive organs are weak.

ASSAM, a province of British India. Until the beginning of 1874 Assam formed the north-east division of the territories under the Lieutenant Governor of Bengal. In that year it was erected into a separate administration, presided over by a Chief Commissioner, who acts directly under the Governor-General of India in council. The district of Cachar was added to the old division of Assam, and now forms part of the Chief Commissioner's jurisdiction. It lies between 24° and 28° N. lat., and between 90° and 98° E. long., and consists of the upper valleys of the Brahmaputra for a length of about 500 miles from where that river enters the north-eastern frontier of British India. These valleys vary in breadth, but generally occupy a space of about 60 miles between the Himálayas on the north, and the watershed which separates the Brahmaputra from the river system of Cachar. Assam, therefore, is bounded on the N. by the sub-Himálayan ranges of the Bhutiá, Aká, Daphlá, and Miri tribes; on the E. by the unsurveyed forests and mountains which separate British India from northern Burmah; on the S. by the hills inhabited by the Nágás, Jaintiyas, and Khásiás, which separate Assam from Silhet; and on the W. by the Gáro hills and Kuch Behar. Assam may be considered, however, either as a natural province or as an artificial political division. In its former aspect, in which it will be dealt with in this article, it has an area of 48,473 square miles, with a population in 1872 of 2,412,480 souls. It is the outlying province of India to the north-east, so that while the pressure of population in several of the inner divisions of Bengal varies from 500 to 573 persons per square mile, in Assam it is barely 50. Even deducting 12,058 miles of hill country in Lakhimpur and Cachar districts, the pressure of population is only 66 persons per square mile in the more cultivated parts of Assam. Taken as a political division, it is locally administered by a Chief Commissioner, with his headquarters at Gauhátí. It is subdivided into the ten following districts, each under a deputy commissioner:—

Table showing the Area, Population, and Land Revenue of the Assam Province

Name of District.	Area in square miles.	Total population.	Pressure of population per square mile.	Hindus.	Muhammadans.	Christians.	Others.	Land Revenue.
1. Goálpárá	4,433	444,761[2]	100	311,419	89,916	141	6,238	£13,045 0 0
2. Kámrúp	3,631	561,681	155	515,024	45,823	204	630	83,200 0 0
3. Dorang or Darang	3,413	236,009	69	221,389	13,859	256	505	36,665 8 0
4. Naogáon	3,648	256,390	70	245,615	10,066	179	530	36,146 8 0
5. Sibságar	2,413	296,589	123	282,969	12,619	283	718	46,829 14 0
6. Lakhimpur	3,145	121,267	39	115,638	3,826	316	1,487	14,383 6 0
7. Cachar	1,285	205,027	160	128,219	74,361	409	2,038	15,334 12 0
8. Nágá Hills	4,900	68,918	14	Not classified	Not classified	Not classified	Not classified	47 6 0
9. Khasiá and Jayantiyá Hills	6,157	141,838	23	Do.	Do.	Do.	Do.	307 16 0
10. Gáro Hills	3,390	80,000	23	Do.	Do.	Do.	Do.	...
	36,415	2,412,480	66	1,820,273	250,470	1,788	12,146	£315,959 10 0

The area given in this table is exclusive of 8343 square miles of hill country in Lakhimpur, and 3715 square miles of the Cachar hills, but it includes the two districts of Goálpára and the Gáro hills, which, although for political convenience placed under the commissioner of the Kuch Behar division of Bengal, belong physically and linguistically to Assam.

History.—Assam was the province of Bengal which remained

[1] *Animals and Plants under Domestication*, vol. i. p. 62.

[2] This includes the population of Eastern Duárs, 37,047, not classified according to religion.

most stubbornly outside the limits of the Mughul empire and of the Muhammadan polity in India. Indeed, although frequently overrun by Musalmán armies, and its western districts annexed to the Muhammadan vice-royalty of Bengal, the province maintained an uncertain independence till its invasion by the Burmese towards the end of the last century, and its final cession to the British in 1826. A full account of its ancient kings will be found in Mr William Robinson's *Assam*, chap. iv. (Calcutta, 1841). It seems to have been originally included, along with the greater part of north-eastern Bengal, in the old Hindu territory of Kámrúp. Its early legends point to great religious revolutions between the rival rites of Krishna and Siva as a source of dynastic changes. Its roll of kings extends deep into pre-historic times, but the first Rájá capable of identification flourished about the year 76 A.D. Kámrúp, the Prágjotishpur of the ancient Hindus, was the capital of a legendary king Narak, whose son Bhagadatta distinguished himself in the great war of the Mahábhárata. On the rise of the Koch power, the kings of Kuch Behar wrested a portion of Assam from the kings of the Pál dynasty to whom it belonged. In the early part of the 13th century the Ahams or Ahoms, from northern Burmah and the Chinese frontiers, poured into the eastern districts of Assam, founded a kingdom, and held it firmly for several centuries. A tradition relates that this race of conquerors were originally let down from heaven by iron chains, and alighted in a place called Mungbingram, supposed to be in the Pátkai range, in 567 A.D. Their manners, customs, religion, and language were, and for a long time continued to be, different from those of the Hindus; but they found themselves compelled to respect the superior civilisation of this race, and slowly adopted its customs and language. The conversion of their king Chuchengpha to Hinduism took place about the year 1611 A.D. and the whole Ahams of Assam gradually followed his example. In mediæval history, the Assamese were known to the Musalmán population as a warlike, predatory race, who sailed down the Brahmaputra in fleets of innumerable canoes, plundered the rich districts of the delta, and retired in safety to their forests and swamps. As the Muhammadan power consolidated itself in Bengal, repeated expeditions were sent out against these river pirates of the north-east. The physical difficulties which an invading force had to contend with in Assam, however, prevented anything like a regular subjugation of the country; and after repeated efforts, the Musalmáns contented themselves with occupying the western districts at the mouth of the Assam valley. The following details will suffice for the history of a struggle in which no great political object was attained, and which left the Assamese still the same wild and piratical people as when their fleets of canoes first sallied forth against the Bengal delta. In 1638, during the reign of the Emperor Sháh Jahán, the Assamese descended the Brahmaputra, and pillaged the country round the city of Dacca; they were expelled by the governor of Bengal, who retaliated upon the plunderers by ravaging Assam. During the civil wars between the sons of Sháh Jahán, the king of Assam renewed his predatory incursions into Bengal; upon the termination of the contest, Aurangzeb determined to avenge these repeated insults, and despatched a considerable force for the regular invasion the Assamese territory. His general, Mír Jumlá, defeated the Rájá, who fled to the mountains, and most of the chiefs made their submission to the conqueror. But the rains set in with unusual violence, and Mír Jumlá's army was almost annihilated by famine and sickness. Thus terminated the last expedition against Assam by the Muhammadans, whose fortunes in this country were never prosperous. A writer of the Muhammadan faith says:—"Whenever an invading army has entered their territories, the Assamese have sheltered themselves in strong posts, and have distressed the enemy by stratagems, surprises, and alarms, and by cutting off their provisions. If these means failed, they have declined a battle in the field, but have carried the peasants into the mountains, burned the grain, and left the country desert. But when the rainy season has set in upon the advancing enemy, they have watched their opportunity to make excursions and vent their rage; the famished vaders have either become their prisoners or been put to death. In this manner powerful and numerous armies have been sunk in that whirlpool of destruction, and not a soul has escaped." The same writer states that the country was spacious, populous, and hard to be penetrated; that it abounded in dangers; that the paths and roads were beset with difficulties; and that the obstacles to conquest were more than could be expressed. The inhabitants, he says, were enterprising, well-armed, and always prepared for battle. Moreover, they had lofty forts, numerously garrisoned and plentifully provided with warlike stores; and the approach to them was opposed by thick and dangerous jungles, and broad and boisterous rivers. The difficulties in the way of successful invasion are of course not understated, as it was the object of the writer to exalt the prowess and perseverance of the faithful. He accounts for their temporary success by recording that "the Musalmán hordes experienced the comfort of fighting for their religion, and the blessings of it reverted to the sovereignty of his just and pious majesty." The short-lived triumph of the Musalmáns might, however, have warranted a less ambitious tone. About the middle of the 17th century the chief became a convert to Hinduism. By what mode the conversion was effected does not clearly appear, but whatever were the means employed, it seems that the decline of the country commenced about the same period. Internal dissensions, invasion, and disturbances of every kind convulsed the province, and neither prince nor people enjoyed security. Late in the 18th century some interference took place on the part of the British Government, then conducted by Lord Cornwallis; but the successor of that nobleman, Sir John Shore, adopting the non-intervention policy, withdrew the British force, and abandoned the country to its fate. Its condition encouraged the Burmese, an aggressive people, to depose the Rájá, and to make Assam a dependency of Ava. The extension of their encroachments on a portion of the territory of the East India Company compelled the British Government to take decisive steps for its own protection. Hence arose the series of hostilities with Ava known in Indian history as the first Burmese war, on the termination of which by treaty in February 1826, Assam remained a British possession. In 1832 that portion of the province denominated Upper Assam was formed into an independent native state, and conferred upon Purandar Sinh, the ex-Rájá of the country; but the administration of this chief proved unsatisfactory, and in 1838 his principality was reunited with the British dominions. After a period of successful administration and internal development, under the Lieutenant-Governor of Bengal, it was erected into a separate Chief-Commissionership in 1874.

Physical Aspects.—Assam is a fertile series of valleys, with the great channel of the Brahmaputra (literally, *the Son of Brahmá*) flowing down its middle, and an infinite number of tributaries and water-courses pouring into it from the mountains on either side. The Brahmaputra spreads out in a sheet of water several miles broad during the rainy season, and in its course through Assam forms a number of islands in its bed. Rising in the Thibetan plateau, far to the north of the Himálayas, and skirting round their eastern passes, not far from the Yang-tse-kiang and the great river of Cambodia, it enters Assam by a series of waterfalls and rapids, amid vast boulders and accumulations of rocks. The gorge, situated in Lakhimpur district, through which the southernmost branch of the Brahmaputra enters, has from time immemorial been held in reverence by the Hindus. It is called the Brahmakunda or Parasurámkunda; and although the journey to it is both difficult and dangerous, it is annually visited by thousands of devotees. After a rapid course westwards down the whole length of the Assam valley, the Brahmaputra turns sharply to the south, spreading itself over the alluvial districts of the Bengal delta, and, after several changes of name, ends its course of 1800 miles in the Bay of Bengal. Its first tributaries in Assam, after crossing the frontier, are the Kundil and the Digaru, flowing from the Mishmi hills on the north, and the Tengápáni and Nawá Dihing, which take their rise on the Singpho hills to the south-east. Shortly afterwards it receives the Dibang, flowing from the north-east; but its principal confluent is the Dihang, which, deriving its origin, under the name of the Sanpu, from a spot in the vicinity of the source of the Sátlej, flows in a direction precisely opposite to that river, and traversing the table-land of Thibet, at the back of the great Himálaya range, falls into the Brahmaputra in 27° 48′ N. lat., 95° 26′ E. long., after a course of nearly 1000 miles. Doubts were long entertained whether the Dihang could be justly regarded as the continuation of the Sanpu; these, however, have been gradually removed by the additional testimony of more recent notices; and as it is now ascertained that the last-named river does not flow into the Irawadi, it appears impossible to account for its course to the sea, except by presuming it to discharge its waters into the Brahmaputra through the channel of the Dihang. Below the confluence, the united stream flows in a south-westerly direction, forming the boundary between the districts of Lakhimpur and Darang, situated on its northern bank, and those of Sadiyá, Sibságar, and Naogáon on the south; and finally bisecting Kámrúp, it crosses over the frontier of the province, and passes into Bengal. In its course it receives on the left side the Burí Dihing, a river having its rise at the south-eastern angle of the province; and lower down, on the opposite side, it parts with a considerable offset termed the Burí Lohit, which, however, reunites with the Brahmaputra 60 miles below the point of divergence, bearing with it the additional waters of the Subansiri, flowing from Thibet. A second offset, under the name of the Kalang River, rejoins the parent stream a short distance above the town of Gauhati. The remaining rivers are too numerous to be particularised. Of these, not less than 61 are distinguished by well-known names, of which 34 flow from the northern, 24 from the southern mountains, and the remainder from sources beyond the confines of Assam. The streams of the south are not rapid, and have no considerable current until May or June. Among the islands formed by the intersection and confluence of the rivers is Májuli, or the Great Island, as it is called by way of pre-eminence. This island extends 55 miles in length by about 10 in breadth, and is formed by the Brahmaputra on the south-east, and the Burí Lohit river on the north-west. A Persian writer, Muhammad Kázim, in describing Assam at the close of the 17th century, makes some observations on its general appearance. He thus speaks of Májuli two centuries ago:—

"An island well inhabited, and in an excellent state of agriculture; it contains a spacious, clear, and pleasant country. The cultivated part is bounded by a thick forest, which harbours elephants, and these animals may be caught here, as well as in four or five other forests in Assam. If there be occasion for them, five or six hundred elephants may be procured in a year."

Describing the country south of the Brahmaputra, the same native author observes:—

"Across the river on the side of Garhgáon is a wide, agreeable, level country that delights the heart of the beholder. The whole face of it is marked with population and tillage; and it presents on every side charming prospects of ploughed fields, harvests, gardens, and groves. From the village of Sálagirá to the city of Garhgáon, a space of about 50 *kos* (100 miles) is filled with such an uninterrupted range of gardens, plentifully stocked with fruit trees, that it appears as one garden. Within them are the houses of peasants, and a beautiful assemblage of coloured and fragrant herbs, and of garden and wild flowers blowing together. As the country is overflowed in the rainy season, a high and broad causeway has been raised for the convenience of travellers from Sálagirá to Garhgáon, which is the only uncultivated ground that is to be seen. Each side of this road is planted with shady bamboos, the tops of which meet and are entwined. Among the fruits which this country produces are mangoes, plantains, jacks, oranges, citrons, limes, and punialeh, a species of amleh, which has such an excellent flavour that every person who tastes it prefers it to the plum. There are also cocoa-nut trees, pepper-vines, areca trees, and the sadij (an aromatic leaf), in great plenty. Sugar-cane excels in softness and sweetness, and is of three colours, black, red, and white; there is ginger free from fibres, and betel vines. The strength of vegetation and fertility of the soil is such that whatever seed is sown, or slips planted, they always thrive. The environs of Garhgáon furnish small apricots, yams, and pomegranates; but as these are wild, and not assisted by cultivation and engrafting, they are very indifferent. The principal crop of this country consists in rice and mash. Ades, a kind of pea, is very scarce, and wheat and barley are never sown."

And in respect to the other great division of the province he remarks:—

"The country which is on the northern side of the Brahmaputra is in the highest state of cultivation, and produces plenty of pepper and areca nuts. It even surpasses the southern portion in population and tillage; but as the latter contains a greater tract of wild forests and places difficult of access, the rulers of Assam have chosen to reside in it for the convenience of control, and have erected in it the capital of the kingdom. The breadth of the northern division from the bank of the river to the foot of the mountains, which is a cold climate and contains snow, is various, but is nowhere less than 30 miles, nor more than 90. The inhabitants of these mountains are strong, have a robust and respectable appearance, and are of a middling size. Their complexions, like those of the natives of all cold climates, are red and white; and they have also trees and fruits peculiar to frigid regions."

This description, written two centuries ago, would apply at the present day. In the upper part of the valley, towards the gorge where the Brahmaputra enters, the country is varied and picturesque, walled in on the north and east by the Himálayas, and thickly wooded from the base to the snow-line. On either bank of the Brahmaputra a long narrow strip of plain rises almost imperceptibly to the foot of the hills. Gigantic reeds and grasses occupy the low lands near the banks of the great river; expanses of fertile rice-land come next; a little higher up, dotted with villages encircled by groves of bamboos and fruit trees of great size and beauty, the dark forests succeed, covering the interior table-land and mountains. The country in the vicinity of the large rivers is flat, and impenetrable from dense tangled jungle, with the exception of some very low-lying tracts which are either permanent marshes or are covered with water during the rains. Jungle will not grow on these depressions, and they are covered either with water, reeds, high grasses, or rice cultivation. On or near such open spaces are collected all the villages. As the traveller proceeds farther down the valley, the country gradually opens out into wide plains. In the western district of Kámrúp the country forms one great expanse, with a few elevated tracts here and there, varying from 200 to 800 feet in height.

Varieties of Soils.—The soil is exceedingly rich and well adapted to all kinds of agricultural purposes, and for the most part is composed of a rich black loam reposing on a gray sandy clay, though occasionally it exhibits a light yellow clayey texture. The land may be divided into three great classes. The first division is composed of hills, the largest group within the valley being that of the Mikir Mountains, which stand out upon the plain. Another set of hills project into the valley at Gauháti. But these latter are rather prolongations of spurs from the Khásiá chain than isolated groups belonging to the plains. The other hills are all isolated, and of small extent. The second division of the lands is the well-raised part of the valley whose level lies above the ordinary inundations of the Brahmaputra. The channels of some of the hill streams, however, are of so little depth that the highest lands in their neighbourhood are liable to sudden floods. On the north bank of the great river, lands of this sort run down the whole length of the valley, except where they are interrupted by the beds of the hill streams. The breadth of these plains is in some places very trifling, whilst in others they comprise a tract of many miles, according to the number and the height of the rocks or hills that protect them from the aberrations of the river. The alluvial deposits of the Brahmaputra and of its tributary streams may be considered as the third general division of lands in Assam. These lands are very extensive, and present every degree of fertility and elevation, from the vast *chars* of pure sand, subject to annual inundations, to the firm islands, so raised by drift-sand and the accumulated remains of rank vegetable matter, as no longer to be liable to flood. The rapidity with which wastes composed entirely of sand newly washed forward by the current during floods become converted into rich pasture, is astonishing. As the freshets begin to lessen and retire into the deeper channels, the currents form natural embankments on their edges, preventing the return of a small portion of water which is thus left stagnant on the sands, and exposed to the action of the sun's rays. It slowly evaporates, leaving a thin crust of animal and vegetable matter. This is soon impregnated with the seeds of the *Saccharum spontaneum* and other grasses that have been partly brought by the winds and partly deposited by the water. Such places are frequented by numerous flocks of aquatic birds, which resort thither in search of fish and mollusca. As vegetation begins to appear, herds of wild elephants and buffaloes are attracted by the supply of food and the solitude of the newly-formed land, and in their turn contribute to manure the soil.

Geology.—Limestone, coal, and petroleum are found; with oil springs, mineral springs, and brine springs. The mountains on the opposite sides of the valley are characterised by distinct systems, those on the north being composed of primitive formations, while those on the south partake largely of sandstone, shell-limestone, and coal. Some valuable minerals are met with. Gold-dust is found in all the rivers flowing from the northern mountains, but it differs in purity and colour, and also in malleability. That which is obtained in the Dikrang is purer than that found in the Brahmaputra, though it is more abundant in the bed of the latter river. Gold-dust is found most plentifully near the foot of the northern hills; it is never sought for in the southern rivers. Beds of iron-ore exist in various places, and tracings of former workings on a large scale remain; but the native article, being undersold by iron imported from England, is now driven out of the market. Coal has also been discovered in beds of considerable magnitude, and from the circumstance of its existence at the two extremities of the province, there appear grounds for the inference that the coal formations of Assam are co-extensive with the whole length of the valley. The extreme difficulty, however, of moving about in those districts, the absence of roads, and the jungly and almost uninhabited state of the country, have tended to prevent the opening up of the mineral deposits of the province. More recently, the largely-extended cultivation of tea, and the consequently increased demand for means of transport and communication, have directed attention to the local supplies of fuel for the river steamers which now navigate the Brahmaputra. In 1864-65, Mr H. B. Medlicott, Deputy-Superintendent of the Geological Survey, visited this province, and reported most favourably of the value and extent of the coal. To the north of the Brahmaputra no coal worth working was found. To the south, in Upper Assam, the principal localities are in the neighbourhood of Jaipur, in the Debrogarh sub-division of the Lakhimpur district, and in the vicinity of Mákum. The chief sites are the Terap, where a minimum thickness of 5 feet of bright clean coal, nearly horizontal, was seen; the Námchik, a tributary of the Dihang, where, within 200 feet in length, three thick beds of good sound coal were seen, one 8 feet thick; and at Jaipur, where a seam of 17 feet thick occurs, of which 10 feet is good bright coal. Several other seams also exist which have never been touched. The inaccessible nature of the country, however, and the want of a trustworthy map, render it quite impracticable at present to obtain even an approximate idea of the extent of area over which these beds range, and of the amount of fuel available. It can, however, be safely asserted that this amount is very large and most valuable. Assays of the Assam coals showed a proportion of ash not exceeding from 2 to 5 per cent. The survey of the country is now being pushed forward. Neither copper nor silver are found in the province. Rock-salt is dug out of the earth, and brine springs are not uncommon, from which salt is made; but the manufacture is costly, and the salt is as expensive as that imported from Liverpool.

Vegetable Products: Tea.—The most important article of commerce produced in Assam is tea. The rice crop covers a very great proportion of the cultivated land, but it is used for local consumption. The tea plantations occupy only a very small area, but they are the one great source of wealth to the province, and the necessities of tea cultivation are the chief stimulants to the development of Assam. The plant was discovered in 1823 by Mr Robert Bruce, who had proceeded thither on a mercantile exploration. The country, however, then formed part of the Burmese dominions. But war with this monarchy shortly afterwards broke out, and a brother of the first discoverer, happening to be appointed to the command of a division of gun-boats employed in some part of the operations, followed up the pursuit of the subject, and obtained several hundred plants and a considerable quantity of seed. Some specimens were ultimately forwarded to the superintendent of the botanic garden at Calcutta. In 1832 Captain Jenkins was deputed by the Governor-General of India, Lord William Bentinck, to report upon the resources of the country, and the tea plant was brought to his especial notice by Mr Bruce; in 1834 a minute was recorded by the Governor-General on the subject, to which it is stated that his attention had been called to it in 1827 before his departure from England. In accordance with the views of that minute, a committee was appointed to prosecute inquiries, and to promote the cultivation of the plant. Communications were opened with China with a view to obtain fresh plants and seeds, and a deputation, composed of gentlemen versed in botanical studies, was despatched to Assam. Some seeds were obtained from China; but they proved to be of small importance, as it was clearly ascertained by the members of the Assam deputation that both the black and the green tea plants were indigenous here, and might be multiplied to any extent; another result of the Chinese mission, that of procuring persons skilled in the cultivation and manufacture of black tea, was of more material benefit. Subsequently, under Lord Auckland, a further supply of Chinese cultivators and manufacturers was obtained—men well acquainted with the processes necessary for the production of green tea, as the former set were with those requisite for black. In 1838 the first twelve chests of tea from Assam were received in England. They had been injured in some degree on the passage, but on samples being submitted to brokers, and others of long experience and tried judgment, the reports were highly favourable. It was never, however, the intention of Government to carry on the trade, but to resign it to private adventure as soon as the experimental course could be fairly completed. Mercantile associations for the culture and manufacture of tea in Assam began to be formed as early as 1839; and in 1849 the Government disposed of their establishment, and relinquished the manufacture to the ordinary operation of commercial enterprise. In 1851 the crop of the principal company was estimated to produce 280,000 lb. Since then the enterprise has rapidly developed. The returns for 1871 show 11,475,398 lb of tea manufactured in Assam, against 9,511,517 in 1870, showing an increase of 1,963,881 lb in one year. There were 416 gardens open, and the whole extent of land held under the different tenures for this purpose was 474,939 acres, of which 54,384 were reported to be under cultivation. The average monthly number of labourers employed on the tea gardens of Assam during 1871 was 54,326, of whom upwards of 38,000 were imported under the Labour Transport Acts, chiefly from the western districts of Lower Bengal. It is to be remembered that Assam now includes Cachar, and these statistics are for the whole province as constituted in 1874. Tea cultivation is steadily progressing in Assam, and has firmly established itself as a staple of Indian trade. Besides rice and tea, the other principal crops of Assam are pulses, Indian corn, oil seeds, sugar-cane, *pán*, hemp and jute, rhea grass, mulberry, potatoes, and other vegetables.

Animals.—The zoology of Assam presents some interesting features. Wild elephants abound and commit many depredations, entering villages in large herds, and consuming everything suitable to their tastes. Many are caught by means of female elephants previously tamed, and trained to decoy males into the snares prepared for subjecting them to captivity. A considerable number are tamed and exported from Assam every year, but the speculation appears to be rather precarious, as it is said about twice the number exported are annually lost in the course of training Many are killed every year in the forests for the sake of the ivory which they furnish; and the supply must be very great which can afford so many for export and destruction without any perceptible diminution of their number. The rhinoceros is found in the denser parts of the forests, and generally in swampy places. This animal is hunted and killed for its skin and its horn. The skin affords the material for the best shields. The horn is sacred in the eyes of the natives. Contrary to the usual belief it is stated that, if caught young, the rhinoceros is easily tamed, and becomes strongly attached to his keeper. Tigers abound, and though many are annually destroyed for the sake of the Government reward, their numbers seem scarcely, if at all, to diminish. Their destruction is sometimes effected by poisoned arrows discharged from an instrument resembling a cross-bow, in which the arrow is first, fixed, and a string connected with the trigger is then carried across the path in front of the arrow, and fastened to a peg. The animal thus struck is commonly found dead at the distance of a few yards from the engine prepared for his destruction. Leopards and bears are numerous; and the *Arctonix Collaris* of Cuvier, a small animal somewhat resembling a bear, but having the snout, eyes, and tail of a hog, is found. Among the most formidable animals known is the wild buffalo, which is of great size, strength, and fierceness. Many deaths are caused by this animal, and a reward is given for its destruction. The fox and the jackal exist, and the wild hog is very abundant. Goats, deer of various kinds, hares, and two or three species of antelope are found, as are monkeys in great variety. The porcupine, the squirrel, the civet cat, the ichneumon, and the otter are common. The birds are too various to admit of enumeration. Wild game is plentiful; pheasants, partridges, snipe, and waterfowl of many descriptions make the country a tempting field for the sportsman. Vultures and other birds of prey are met with. Crocodiles (commonly called alligators) swarm in all parts of the Brahmaputra, and are very destructive to the fish, of which hundreds of varieties are found, and which supply a valuable article of food. The most destructive of the *feræ naturæ*, as regards human life, are, however, the snakes. Of these, several poisonous species exist, including the cobra and karait (*Naga tripudians* and *Bungarus cæruleus*). The bite of a fairly-grown healthy serpent of either of these species is deadly; and it is ascertained that more deaths occur from snake-bite than from all the other wild beasts put together. Among the non-poisonous serpents, the python ranks first. This is an enormous boa-constrictor, of great length and weight, which drops upon his prey from the branch of a tree, or steals upon it in the thick grass. He kills his victim by rolling himself round the body till he breaks its ribs, or suffocates it by one irresistible convolution round its throat. He seldom or never attacks human beings unless in self-defence, and loss of life from this cause is scarcely ever reported. Full details as to the botany and zoology of Assam will be found in Mr William Robinson's account of the province (Calcutta, 1841).

The Inhabitants of the entire province number nearly two and a half millions, of whom more than one million and three-quarters are Hindus; 250,490 are Muhammadans, 1788 are Christians, and the remaining third of a million are hill tribes, professing aboriginal faiths. The native population is so exceedingly sparse that the demand for labour on the tea gardens has given rise to a system of importing coolies from western Bengal. A series of laws, regulate the terms of the contract between the planter and the imported labourer, prevent abuses in recruiting coolies among the ignorant peasantry of the west, and provide for their health and comfort during their transit to the distant districts of Assam. Under these Acts 4988 labourers were imported into the tea districts of Assam (including Cachar) in 1871, the total number of imported labourers employed on the tea plantations at the end of that year being 39,426. A large proportion of the native inhabitants derive their origin from tribes who came from the Himálayan ranges, from Burmah, or from the Chinese frontier. The most important of these are the Ahams or Ahoms, an offshoot of the Shan race of Northern Burmah. They were the last conquerors of Assam before the Burmese, and they long preserved their ancient traditions, habits, and institutions. Hinduism first made its encroachments among their kings and nobility. Several generations ago they gave up eating beef, and they are now completely Hinduised, except in a few remote recesses of Assam. Hinduism has also impressed its language upon the province, and the vernacular Assamese possesses a close affinity to Bengali, with the substitution of *s* for the Bengali *ch*, of a guttural *h* for the Bengali *h* or *sh*, and a few other dialectic changes. Indeed, so close was the resemblance that during the last thirty years Bengali was used as the court and official language of the province under our rule. But with the development of the country the Assamese tongue has asserted its claims to be treated as a distinct vernacular, and a late resolution of Government (1873) re-established it as the language of official life and public business.

The Assam peasant, living in a half-populated province, and surrounded by surplus land, is indolent, good-natured, and, on the whole, prosperous. He raises sufficient food for his wants with very little labour, and, with the exception of a few religious ceremonies, he has no demand made upon him for money, saving the light rental of his fields. Under the peaceful influences of British rule, he has completely lost his ancient warlike instincts, and forgotten his predatory habits. In complexion he is a shade or two fairer than the Bengali. His person is in general short and robust, but devoid of the grace and flexibility of the Hindu. A flat face, with high cheek-bones, presents a physiognomy resembling the Chinese, and suggests no idea of beauty. His hair is abundant, black, lank, and coarse, but the beard is scanty, and usually plucked out, which gives him an effeminate appearance. The women form a striking contrast to the men; there is more of feminine beauty in them than is commonly seen in the women of Bengal, with a form and feature somewhat approaching the European. In most parts of the country the women of rank go about in public, without that artificial modesty practised by native ladies in other parts of India. Although the ancient ruling classes originally came to the province across the Himáláyas or from Burmah, a stream of immigration also went on from Bengal, and the Nadiyáls or Doms, who originally emigrated from the Delta, are said to be the most numerous tribe in Assam. Their original employment was that of fishermen. Although a very low caste, and indeed one of the outcastes among the Hindus of Bengal, they observe in Assam various rules of purity in eating and drinking, with a greater strictness than even the Bráhmans. They have not, however, taken a Bráhman as their spiritual guide, but follow the instructions of the Kalitás, the ancient priests of the Ahams. The habits of life of the Assamese peasantry are pre-eminently domestic. Great respect is paid to old age; when parents are no longer capable of labour they are supported by their children, and scarcely any one is allowed to become a burden to the public. They have also in general a very tender regard for their offspring, and are generous and kind to their relations. They are hospitable to people of their own caste, but to no others. The use of opium is very general among the Assamese.

Hill Tribes.—The hill and frontier tribes of Assam are the Nágás, Singphos, Daphlás, Miris, Khámptis, Mataks, Abars, &c., nearly all of whom, excepting the Nágás, are found near the frontiers of Lakhimpur district. The principal of these, in point of numbers, are the Nágás, who inhabit the hills and forests along the eastern and south-eastern frontier of Assam. They generally live in small scattered communities of about twenty houses each, and are divided into numerous clans or *khels*, of which the six most important residing in British territory are the following, viz., the Námsangiás, Bardwáriás, Paindwáriás, Laptangs, Kaimais, and Topigamaiás. Exclusive of the Nágá Hills district of Assam, the population of which is returned at 68,918, the Nágás of Lakhimpur count 2865 houses, with an estimated population of 14,353 souls. They cultivate rice, cotton, yams, and Indian corn, and prepare salt from the brine springs in their hills. The different tribes of Nágás are independent of and unconnected with one another, and are often at war with each other. The Singphos are the most powerful tribe bordering on the Assam valley, and are scattered over the largest extent of country. Their territory is bordered on the north by the upper reaches of the Brahmaputra; on the south by the Pátkai range; on the west by an imaginary line drawn south from the town of Sadiyá to the Pátkai mountains; on the east by the Langtung mountains. They are a wild, daring tribe; and in the early days of English rule in Assam they gave a good deal of trouble by their frequent raids. They are now, however, looked upon as peaceful and friendly neighbours. They have settled down to agriculture, and now do for themselves what formerly they depended on their Assamese slaves to perform for them. They only cultivate sufficient food for a portion of the year, and during the remaining months they live upon wild yams and other jungle products. The Government has no very definite relations with them; but they are generally obedient, and in a loose way recognise British supremacy. The settlements of the Singphos in or near the frontier of Lakhimpur are estimated to number about 3435 souls. The other tribes are the Khámtis, Abars, Miris, Mishmis, and Daphlás.

Slavery, which existed in a mild form until our acquisition of Assam, has ceased under British rule.

ADMINISTRATION.—The administrative statistics of the province will be given separately for each of the ten districts mentioned in the foregoing table under their alphabetical headings. Here it will suffice to say, that Assam as a whole is under a Chief Commissioner who is directly responsible to the Governor-General in council. The Assam districts form what is called a non-regulation province—*i.e.*, one to which it has not been found expedient to extend our system of government in its strict legal entirety. Each district, instead of being under a judge and a magistrate-collector, with their separate sets of subordinates, is managed by a deputy-commissioner, in whom both the executive and judicial functions are combined. It is essentially an outlying province, yielding very little revenue to Government, and administered as cheaply as practicable. With the exception of Goálpárá, the land revenue of Assam is at present under a light temporary settlement, the permanent settlement not having yet been extended to it on account of its sparse population and backward state. The population is essentially agricultural, and no tendency appears on their part to gather into trading centres or to develop city life. Throughout the whole province there are only two towns with a population of upwards of 5000 souls, viz., Gauhátí, population 11,492; and Sibságar, 5278. The various Government rules for granting waste lands in fee-simple or on long leases at easy rates, have brought a considerable number of English capitalists and speculators into the province. It is on these grants that many of the tea-gardens have been formed. The development of European enterprise has created a sudden and an urgent demand for roads, which the Government has hitherto not found itself in a position to meet. For all the ordinary purposes of the province, and for its heavy and bulky staples, such as timber, rice, food grains, and oil seeds, the Brahmaputra and its tributaries afford ample means of transit. The great trunk road, which the Muhammadans drove through Assam with a view to controlling the turbulent population, has long ago fallen into decay, and at many places is only recognisable as a line of fragmentary embankments. Each district, however, is now developing a system of roads, or at any rate of country tracks, of its own; and Sir George Campbell, the present Lieutenant-Governor of Bengal (1874), initiated a liberal policy towards the Assam communications, with the view rather to the future of the province than to the amount of expenditure which its revenue at present warrants. Now that it is erected into a separate administration, a still more rapid progress may be looked for. With its vast forests, its inexhaustible rice-grounds, its coal, iron, and tea, and the cheap means of transit which its rivers afford, Assam, although at present one of the most backward among Indian provinces, has capabilities of development such as no other part of Bengal possesses. (W. W. H.)

ASSAROTTI, OTTAVIO GIOVANNI BATTISTA, the founder of schools for the education of deaf-mutes in Italy, was born at Genoa in 1753. He received an excellent education; and after qualifying himself for the church, he entered the society of the Pietists, "Scuole Pie," who devoted themselves to the training of the young. His superior learning rendered his services very valuable, and he was appointed to lecture on theology to the students of the order. In 1801 he heard of the Abbe Sicard's experiments in the training of deaf-mutes, and resolved to try something similar in Italy. He began with one pupil, and had by degrees collected a small number round him, when, in 1805, Napoleon, hearing of his endeavours, ordered a convent to be given him for a school-house, and funds for supporting twelve scholars to be taken from the convent revenues. This order was scarcely attended to till 1811, when it was renewed, and in the following year Assarotti, with a considerable number of pupils, took possession of the new school. Here he continued, with the exception of a short interval in 1814, till his death in 1829. A pension, which had been awarded him by the king of Sardinia, he bequeathed to his scholars. Nothing definite is known as to the method of instruction pursued by Assarotti; he seems, in fact, to have followed no fixed plan.

ASSASSINS, a secret military and religious sect formed in Persia and Syria during the 11th century A.D. To understand clearly its nature and tenets, it is necessary to refer to the doctrines of the Ismaelites, of whom it was a branch, and who were themselves an offshoot from the great body of the Shiites. The Shiites, one of the two sects into which the Mahometans had separated, held in opposition to the Sunnites, or orthodox, that the true and only legitimate successor of the Prophet was his son-in-law, Ali. They did not succeed in establishing by force the claims of this family; and, under the dynasties of the Ommiade and Abbaside caliphs, they were compelled to keep their opinions secret. The large body of Shiites was further divided into several distinct parties, differing principally with regard to the recognised line of succession from Ali; of these the most powerful was that of the Ismaelites, so called because they held that the Imamat descended in an unbroken line from Ali to Ismael, his seventh successor. The adherents of this sect were most widely spread in Persia, and naturally the special object of their opposition was the Abbaside caliphate of Baghdad, but no active steps were taken by them, until under one of the Persian magi, Abdallah-ibn-Maimun Kadah, they had been organised into a secret society, with definite political objects and peculiar religious or philosophical views. Abdallah, like many of his countrymen, was a free-thinker, and he succeeded in establishing among the Ismaelites a faith, or rather a philosophy, wholly opposed to the doctrines of Islam. The fundamental principles of his creed appear to have been—(1.) The rejection of all fixed rules either of religion or morality; all actions were therefore indifferent, only the internal disposition was of any value; (2.) The belief that the Imams of the line of Ismael were at present invisible, and that, consequently, it was the duty of true believers to yield implicit obedience to the vicegerents on earth of these secret rulers; (3.) The allegorical interpretation of the Koran, whereby any doctrine might be either defended or rejected. He also established a regular system of grades or a hierarchy of ranks among the members of the society; only a few members were fully initiated into the philosophy of indifference, the others were kept in a state of profound ignorance, for the rulers knew how necessary this was in order to secure their obedience.

The first open attempt to put their principles into practice was made by one Ahmed, surnamed Karmath, whence his followers were called Karmathites. After a sanguinary struggle with the caliphs, lasting during many years, this revolt was quelled. But about the same time an adherent of the sect, named Abdallah, a lineal descendant of Ismael, escaped from prison, into which he had been thrown, and, making his way to Egypt, succeeded in placing himself upon the throne of that country. Under the name of Obeid-Allah-Mahdi, he founded the dynasty of the Fatimites, who took their title from their ancestress, the daughter of Mahomet. Ismaelism thus secured a firm footing in the west, and its doctrines were propagated there with great success. At Cairo a grand lodge was formed in which their philosophical principles were perfected, and the process of initiation carried on in its several grades. While this lodge was at the height of its prosperity there arrived in Egypt a learned *dai* or missionary of the Eastern

Ismaelites, called Hassan Ben Sabbah. The father of this man, a native of Khorassan, and an adherent of the Shiites, had been frequently compelled to profess Sunnite orthodoxy, and from prudential motives had sent his son to study under an orthodox doctor at Nishapur. Here Hassan made the acquaintance of Nizam-el-Mulk, afterwards vizier of the Sultan Malik-Shah. During the reign of Alp-Arslan he remained in obscurity, and then appeared at the court of Malik-Shah, where he was at first kindly received by his old friend the vizier. Hassan, who was a man of great ability, tried to supplant him in the favour of the sultan, but was outwitted and compelled to take his departure from Persia. He went to Egypt, and, on account of his high reputation, was received with great honour by the lodge at Cairo. He soon stood so high in the Caliph Mostansar's favour as to excite against him the jealousy of the chief general, and a cause of open enmity soon arose. The caliph had nominated first one and then another of his sons as his successor, and in consequence a party division took place among the leading men. Hassan, who adopted the cause of Nezar, the eldest son, found his enemies too strong for him, and was forced to leave Egypt. After many adventures he reached Aleppo and Damascus, and after a sojourn there, settled near Kuhistan. He gradually spread his peculiar modification of Ismaelite doctrine, and having collected a considerable number of followers, formed them into a secret society. In 1090 he obtained, it is said by stratagem, the strong mountain fortress of Alamut in Persia, and removing there with his followers, settled as chief of the famous society afterwards called the Assassins.

The speculative principles of this body were identical with those of the Ismaelites, but their external policy was marked by one peculiar and distinctive feature—the employment of secret assassination against all enemies. This practice was introduced by Hassan, and formed the essential characteristic of the sect. In organisation they closely resembled the western lodge at Cairo. At the head was the supreme ruler, the *Sheikh-al-Jebal, i.e.*, Chief, or, as it is commonly translated, Old Man of the Mountains. Under him were three *Dai-al-Kirbal*, or, as they may be called, grand priors, who ruled the three provinces over which the sheikh's power extended. Next came the body of *Dais*, or priors, who were fully initiated into all the secret doctrines, and were the emissaries of the faith. Fourth were the *Refiks*, associates or fellows, who were in process of initiation, and who ultimately advanced to the dignity of *dais*. Fifth came the most distinctive class, the *Fedavies*, or *Fedais* (*i.e.*, the devoted ones), who were the guards or assassins proper. These were all young men, and from their ranks were selected the agents for any deed of blood. They were kept uninitiated, and the blindest obedience was exacted from and yielded by them. When the sheikh required the services of any of them, the selected *fedais* were intoxicated with the *hashish*, an opiate made from the juice of hemp leaves, and from which the name Assassin is derived. When in this state they were introduced into the splendid gardens of the sheikh, and surrounded with every sensual pleasure. Such a foretaste of Paradise, only to be granted by their supreme ruler, made them eager to obey his slightest command; their lives they counted as nothing, and would resign them at a word from him. Finally, the sixth and seventh orders were the *Lasiks*, or novices, and the common people. Hassan well knew the efficacy of established law and custom in securing the obedience of a mass of people; accordingly, upon all but the initiated, the observances of Islamism were rigidly enforced. As for the initiated, they knew the worthlessness of positive religion and morality; they believed in nothing, and scoffed at the practices of the faithful. The Assassins soon began to make their power felt. One of their first victims was Hassan's former friend, Nizam-el-Mulk, whose son also died under the dagger of a secret murderer. The death by poison of the Sultan Malik-Shah was likewise ascribed to this dreaded society, and contributed to increase their evil fame. Sultan Sanjar, his successor, made war upon them, but he was soon glad to come to terms with enemies whose operations were invisible, and against whom no precaution seemed available. After a long and prosperous rule Hassan died at an advanced age in 1124. He had previously slain both his sons, one on suspicion of having been concerned in the murder of a *dai* at Kuhistan, the other for drinking wine, and he was therefore compelled to name as his successor his chief *dai*, Kia-Busurg-Omid.

During the fourteen years' reign of this second leader, the Assassins were frequently unfortunate in the open field, and their castles were taken and plundered; but they acquired a stronghold in Syria, while their numerous murders made them an object of dread to the neighbouring princes, and spread abroad their evil renown. A long series of distinguished men perished under the daggers of the *fedais*; even the most sacred dignity was not spared. The Caliph Mostarschen-ali-Mansur was assassinated in his tent, and not long after, the Caliph Rashid suffered a similar fate. Busurg-Omid was succeeded by his son Mahomet I., who, during the long period of 25 years, ruthlessly carried out his predecessor's principles. In his time Massiat became the chief seat of the Syrian branch of the society. Mahomet's abilities were not great, and the affections of the people were drawn towards his son Hassan, a youth of great learning, skilled in all the wisdom of the initiated, and popularly believed to be the promised Imam become visible on earth. The old sheikh prevented any attempt at insurrection by slaying 250 of Hassan's adherents, and the son was glad to make submission. When, however, he attained the throne, he began to put his views into effect. On the 17th of the month Ramadan, he assembled the people and disclosed to them the secret doctrines of the initiated; he announced that the doctrines of Islam were now abolished, that the people might give themselves up to feasting and joy, for he was the promised Imam, the Caliph of God upon earth. To substantiate these claims he gave out that he was not the son of Mahomet, but was descended from Nezar, son of the Egyptian Caliph Mostansar, and a lineal descendant of Ismael. After a short reign of four years Hassan was assassinated by his brother-in-law, and his son Mahomet II. succeeded. One of his first acts was to slay his father's murderer, with all his family and relatives; and his long rule, extending over a period of 46 years, was marked by many similar deeds of cruelty. He had to contend with many powerful enemies, especially with the great Atabeg Sultan Noureddin, and his more celebrated successor, Jusuf Salaheddin, or Saladin, who had gained possession of Egypt after the death of the last Fatimite caliph, and against whom even secret assassination seemed powerless. During his reign, also, the Syrian branch of the society, under their *dai*, Sinan, made themselves independent, and remained so ever afterwards. It was with this Syrian branch that the Crusaders made acquaintance; and it appears to have been their emissaries who slew Count Raymond of Tripoli and Conrad of Montserrat.

Mahomet III. died from the effects of poison, administered, it is believed, by his son, Jelaleddin Hassan III., who succeeded. He restored the old form of doctrine,—secret principles for the initiated, and Islamism for the people,—and his general piety and orthodoxy procured for him the name of the new Mussulman. During his reign of 12 years no assassinations occurred and he obtained a high reputation among the neighbouring princes. Like his father, he was removed by poison, and his son, Ala-eddin Mahomet III., a child of nine years of age, weak in mind and body, was placed on the throne. Under his rule the mild principles of his father were deserted, and a fresh course of assassination entered on. In 1255, after a reign of 30 years, Alaeddin was slain, with the connivance of his son, Rokneddin, the last ruler of the Assassins. In the following year Hulaku, brother of the Tatar, Mangu Khan, invaded the hill country of Persia, took Alamut and many other castles, and captured Rokneddin. He treated him kindly, and, at his own request, sent him under escort to Mangu. On the way, Rokneddin treacherously incited the inhabitants of Kirdkuh to resist the Tartars. This breach of good faith was severely punished by the khan, who ordered Rokneddin to be put to death, and sent a messenger to Hulaku commanding him to slay all his captives. About 12,000 of the Assassins were massacred, and their power in Persia was completely broken. The Syrian branch flourished for some years longer, till Bibars, the Mameluke sultan of Egypt, ravaged their country and nearly extirpated them. Small bodies of them lingered about the mountains of Syria, and are believed still to exist there. Doctrines somewhat similar to theirs are to be met with among the Druses, and particularly among the Ansarii or Nosarii, a small Syrian people, dwelling not far from Latakia. Some writers have thought that these Ansarii are the remnants of the Assassins, but this does not seem possible, for the two sects are at enmity, and in 1809 the stronghold of Massiat, then in possession of some Ismaelites, was attacked and pillaged by the Ansarii.

See Von Hammer, *Geschichte der Assassinen*, 1818; De Sacy, *Mémoires de l'Institut*, iv., 1818, who discusses the etymology fully; *Calcutta Review*, vols. iv. lvi.; A. Jourdain in Michaud's *Histoire des Croisades*, ii. pp. 465–484, and translation of the Persian historian Mirkhond in *Notices et Extraits des Manuscrits*, xiii. p. 143, *sq.* On the Ansarii, see Michaud et Poujoulat, *Correspondance d'Orient*, vi. p. 458, *sq.*; and F. Walpole, *The Ansayrii, or Assassins*, 3 vols., 1851.

ASSAULT, in English Law, is defined "as an attempt or offer with force or violence to do corporal hurt to another, as by striking at another with a stick or other weapon, or without a weapon, though the party misses his aim." Notwithstanding ancient opinions to the contrary, it is now settled that mere words, be they ever so provoking, will not constitute an assault. Coupled with the attempt or threat to inflict corporal injury, there must in all cases be the means of carrying the threat into effect. A *battery* is more than a threat or attempt to injure the person of another; the injury must have been inflicted, but it makes no difference however small it may be, as the law does not "draw the line between degrees of violence," but "totally prohibits the first and lowest stage of it." Every battery includes an assault. A common assault is a misdemeanour, and is punishable by one year's imprisonment with hard labour, but severer penalties are provided for the various kinds of aggravated assaults.

ASSAYE, a village of Haidarábád, in the Nizám's dominions, in Southern India, situated in 20° 18′ N. lat. and 75° 55′ E. long. The place is celebrated as the site of a battle fought on the 23d September 1803 between the combined Marhattá forces under Sindhiá and the Rájá of Berar and the British under Major-General Wellesley, afterwards the Duke of Wellington. The Marhattá force consisted of 50,000 men, supported by 100 pieces of cannon entrenched in a strong position. Against this the English had but a force of 4500 men, which, however, after a severe struggle, gained the most complete victory that ever crowned British valour in India. Assaye is 261 miles N.W. of Haidarábád.

ASSAYING. This term is used in metallurgy to denote a chemical operation in which the quantity of one ingredient of a mineral or alloy is determined; it is chiefly used in reference to the precious metals, gold and silver, and it is in this connection that the subject will here be treated of. In the wider acceptation of the term in which it is used amongst practical metallurgists, *assaying* means almost the same thing as the quantitative estimation of one constituent of a compound, when the process adopted is one which has to be frequently repeated in a laboratory, and the results are required for commercial purposes. In this sense we speak not only of the assay of gold and silver, but of other metals, such as lead and copper, of non-metallic elements, such as sulphur and iodine, and even of compounds such as nitre. The operations of assaying were, until recently, chiefly performed by what is called the dry method, but of late years the processes of volumetric analysis have been so largely introduced into the metallurgical laboratory, that the wet method is almost as much used as the dry method. In the processes of assaying the precious metals described in the following pages, the reader will have both these terms explained, for gold is assayed in the dry, while silver is assayed in the wet way.

The precious metals, gold and silver, being almost universally used as convenient representatives of value, and as such passing frequently between one country and another, it is of the utmost importance to ascertain, quickly and accurately, the marketable value of any sample of gold or silver bullion. Were these metals invariably used in their pure state, their commercial value would be in direct proportion to their weight, and all that would have to be known would be the actual value of a pound of gold or silver; but the metals exist in commerce in the form of alloys or mixtures containing an indefinite amount of base metal. Gold is generally alloyed with copper and silver, whilst silver is generally alloyed with copper. The problem is, therefore, to ascertain by some ready process, which admits of extreme accuracy as well as moderate rapidity, the exact proportion of pure gold present in an alloy, ore, or mixture containing this metal; and inasmuch as silver is also a precious metal, the assay of gold almost always involves the assay of the silver which accompanies it, for in many cases the amount of silver present may be sufficient to increase the commercial value of the substance under assay. It is very seldom, however, that the copper or other metal present is in sufficient quantity to be of value, unless, indeed, the substance under assay be a copper ore or pyrites containing only traces of gold. In the case of silver assay, when the base metal is copper, it is generally neglected. It is, however, frequently necessary to examine silver for gold, for, formerly, the methods of parting these two precious metals were by no means so exact as they are now, and on this account old silver frequently contains an amount of gold which it will pay well to extract by modern methods. The principle of assaying gold and silver is very simple theoretically, but in practice great experience is necessary to ensure accuracy, and there is no branch of business which more demands personal and undivided attention.

All substances containing gold may be divided into two classes. The first class comprises ores containing gold in a mineralised form. These include graphic tellurium and foliated tellurium, and are of no commercial importance. For the present purpose, we need simply mention the substances in the second class, which consist of *alloys* of gold, and include *native gold*, containing from 65 to 99 per cent. of gold; *palladium gold*, containing about 86 per cent. of gold; *rhodium gold*, containing from 59 to 66 per cent. of gold; *gold amalgam*, containing 38 per cent. of gold; and *artificial alloys*, as gold coin, jewellery, &c. Of the foregoing list, the only alloys which are of commercial importance are, *native gold* and *artificial alloys*. Native gold is commonly found in a quartzose gangue, and nearly always associated with iron and copper pyrites, mispickel or arsenical pyrites, blende, galena, many antimonial minerals, and nearly all the primitive rocks.

The only artificial alloys of gold which will be specially noticed here are the standard gold of this realm, and alloys of gold with silver or copper used for jewellery. The standard of alloys of gold is expressed in fractions of unity. It is assumed that there are 24 carats in unity, and $\frac{32}{32}$nds in the carat. Standard gold, in the 24 carats, contains 22 carats of pure or fine gold, as it is called, and two carats of alloying metal, either silver or copper, or a mixture of the two. Standard gold is, therefore, called 22-carat gold. In a similar way articles of jewellery are denominated 12-carat, 16-carat, 18-carat, &c., according to the proportion of fine gold alloyed with the inferior metal. An ordinary assay report of gold expresses the variation from the standard, and not the fine metal contained in it, and it is, therefore, marked as either better or worse than standard. The standard of gold being 22 carats fine and 2 alloy, an ingot of gold found to contain only 21 carats pure gold would be reported *worse* 1 carat. If it contained 23½ carats, it would then be reported *better* 1½ carat.

The processes by which gold is generally assayed are *cupellation*, when the alloy consists of copper, and *parting*, when the alloy consists of silver. Generally speaking, both operations are necessary. We will describe them as they would be performed in practice. When the standard of the alloy to be examined is not approximatively known, a preliminary assay must be made to ascertain the quantity of lead necessary to fuse with the gold alloy. But in most cases this is unnecessary, as, from the circumstances of the case, the standard of the alloy is generally known within sufficiently close limits.

The process of cupellation is briefly as follows:—The gold alloy is fused with a quantity of lead, and a little silver if silver is already present. The resulting alloy, which is called the *lead button*, is then submitted to fusion on a very porous support, made of bone-ash, and called a *cupel*. The fusion being effected in a current of air, the lead oxidises. The heat is sufficient to keep the resulting oxide of lead fused, and the porous cupel has the property of absorbing melted oxide of lead without taking up any of the metallic globule, exactly in the same way that blotting-paper will absorb water whilst it will not touch a globule of mercury. The heat being continued, and the current of air always passing over the surface of the melted lead button, and the oxide of lead or *litharge* being sucked up by the cupel as fast as it is formed, the metallic globule rapidly diminishes in size until at last all the lead has been got rid of. Now, if this were the only action, little good would have been gained, for we should simply have put lead into the gold alloy, and then taken it out again; but another action goes on whilst the lead is oxidising in the current of air. Other metals, except the silver and gold, also oxidise, and are carried by the melted litharge into the cupel. If the lead is therefore rightly proportioned to the standard of alloy, the resulting button will consist of only gold and silver, and these are separated by the operation of *parting*, which consists in boiling the alloy (after rolling it to a thin plate) in strong nitric acid, which dissolves the silver and leaves the gold as a coherent sponge. To effect this parting properly, the proportion of silver to gold should be as 3 to 1. The operation by which the alloy is brought to this standard is termed *quartation* or *inquartation*, and consists in fusing the alloys in a cupel with lead and the quantity of fine silver or fine gold necessary to bring it to the desired composition.

What is called the *Trial of the Pyx* is an ancient ceremony which takes place about once in every three years, at which the standard coin of the realm is carefully assayed. For a description of this see the article COINAGE.

It is unnecessary in the present work to describe the various delicate operations which we have briefly alluded to above, but we will describe the implements and furnaces which have been introduced and adopted in the Royal Mint by Mr H. W. Field, the late resident assay-master of that establishment.

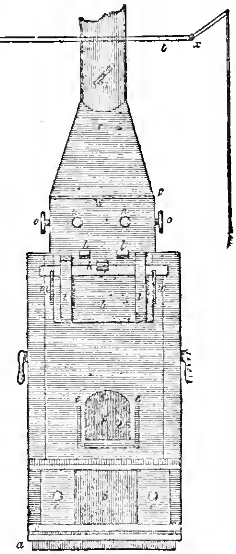

FIG. 1.—Front elevation of Furnace.

Fig. 1 is the front elevation of the furnace; *a*, a view of the front iron roller on which it rests, *b*, the ash-pit; *cc* are the dampers moving horizontally from side to side towards each other, meeting exactly in the centre; *d*, the muffle door by which the assays are introduced; *ee*, the door slides. So far, the furnace is similar to that formerly in use, except that the bars on which the muffle stands run from front to back, and are movable, rendering the removal of the brick-work unnecessary. By this means the muffle stand is easily introduced, and, having steady pins on the under side, it is raised about an inch above the bars. The furnace measures 2 feet 10 inches in height, 1 foot 7 inches in width, and 1 foot 11 inches in depth. Instead of the furnace, as formerly, being fed at the top, the fuel is charged by the door *h*, which also affords the means of regulating the draught, and of throwing a current of air through the muffle by the door *d*. This door has a bar *k*, traversing about two-thirds of it, running easily from the top towards the bottom within *ii*, with a ketch *m*, on each side to keep it close. These are made on an incline, and about 3½ inches long, so as to allow the traversing bar to slide freely when the door is not required to be closed. In this manner the door may be opened from a quarter of an inch to the extent of three inches. This feeding and regulating door is fixed by hinges *ll* to the front part of the *iron frame* covering the brick lining on the top of the furnace. On this frame rests the square dome *r*, the front of which, *w*, is removable by two handles *nn*; and by taking out the two thumb-screws *oo*, the door and part of the frame come away, leaving a large opening, so as to enable the furnace to be cleaned, the muffle repaired, &c. The furnace should be placed in a recess, under a chimney, with a movable iron ceiling *t*, about 1 foot above the dome, fitting close in every part, so that the draught of air may pass through the furnace. A door, or flap, *x*, is attached to the iron ceiling by a hinge opening on the side of the recess, with means to fix it at any point required, so that the current of air may be regulated by the operator; *s*, a swivel door affords another mode for damping the furnace.

Fig. 2 is a section of the furnace fig. 1; *aa*, the two rollers on which the furnace is placed; *bb*, the slides on which the ash-pit doors run; *c*, the door and ash-pit; *d*, the iron casing to the furnace; *e*, the brick lining; *f*, the ash-pit; *gg*, the two bars inserted in the brick lining,—one in front, one at the back supporting the furnace bars, which can easily be removed at pleasure; *h*, one of the bars on which the muffle plate rests; *i*, a movable tray on which the mouth coal is placed; *k*, a section of a muffle charged with its full complement of 50 cupels, showing also the rows of holes over each row of cupels, through which a current of air passes; similar holes are placed at the back in three rows; they are not pierced through horizontally, but slope towards the ceiling of the muffle at such an angle so as to exclude the ashes; *l* represents the extra covering of fire-clay; *m*, the anthracite coal, showing the level; *n*, the feeding and regulating door; *o*, the ketch or inclined plane on which the sliding-bar travels; *p*, the door, with running staples in which the bar slides; *q*, the mode in which the movable front is brought round and fixed by the thumb-screws *r*; *sv*, the hood; *t*, handle for removing the front; *wx*, the damper and handle.

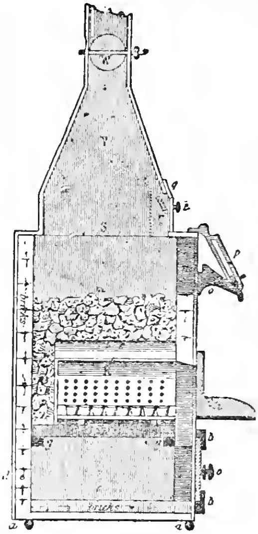

FIG. 2.—Section of Furnace.

Fig. 3 represents the upper interior view of the furnace bars with the muffle stand or plate, showing also the space intended for the fuel.

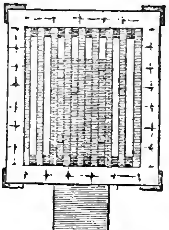

FIG. 3.—Section of Furnace.

Fig. 4 is the mouth of the muffle door, representing the mode of regulating the current of air by cylinders of charcoal.

Fig. 5 is the movable muffle door.

Fig. 6 is a representation of a muffle, $14\frac{1}{2}$ inches long, $7\frac{1}{2}$ inches wide, until it begins to taper at about $1\frac{1}{2}$ inches from the front (see fig. 7), when it does not exceed $5\frac{1}{2}$ inches. The height is $6\frac{1}{2}$ inches, in the clear $5\frac{5}{8}$ inches. Its sides are perforated with holes about a quarter of an inch in diameter.

Fig. 4.

Fig. 5.

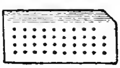

Fig. 6.

Fig. 7.

Fig. 8 is an annealing-iron for softening the assays after they are flattened and rolled. It resembles a square bar of iron about $\frac{1}{8}$th of an inch thick, having strengthening pieces rivetted at each end and two in the middle *bbb*, between which are receiving places for the assays *aaa*. The apertures are made diagonally, as shown by *ccc*, that the assays may not fall completely to the bottom of the box, so that they may be conveniently removed. The under part of the box has a kind of double keel *d* rivetted on it, so that in taking it from the furnace there be no danger of upsetting it on the *annealing trident*.

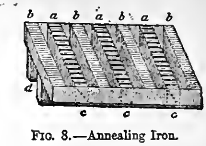

FIG. 8.—Annealing Iron.

Fig. 9 represents the trident for removing the annealing-iron from the furnace.

FIG. 9.—Trident.

Fig. 10 represents the cupel mould; fig. 11 being the section of the same, showing the four pieces of which it consists. The mould is circular, made of forged steel nicely turned. There are several substances of which cupels may be made, but the one in general use is the ash of burnt bones. This consists principally of phosphate of lime, with a little carbonate and some fluoride of calcium. The bones of sheep and horses are best for cupels. They should be burnt until they are quite white, care being taken not to heat the bone-earth too strongly. It must then be finely ground, sifted, and washed several times with boiling distilled water till all soluble salts are removed. The finest particles of the powdered bone-earth will remain longest suspended in the washing waters. This must be allowed to settle separately, and should be reserved for giving a final coating to the surface of the cupels. For the body of the cupels the bone-ash should be about as fine as wheat flour. The bone-ash being moistened with a quantity of water, just sufficient to make the particles adhere, is put into the mould *a*, fig. 11, and pressed down level with the surface. The mould is then put together, as in fig. 10, and the pestle struck with a hammer so as to compress the bone earth into a solid cake. The surface of the cupel may then have sifted over it a little of the very fine levigated bone-ash, and the pestle again hammered on it. The pestle is to be turned lightly round so as to smooth the inner surface of the cupel, and then withdrawn. The cupel is removed from the mould by gentle pressure on the narrowest end. It must be dried gently by a stove, and lastly ignited in a muffle to expel all moisture. It is then ready for use.

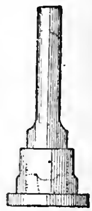

FIG. 10.—Cupel Mould.

FIG. 11.—Section of Cupel Mould.

Fig 12 shows the appearance of the finished cupel, which is generally 1 inch by $\frac{7}{8}$ths of an inch.

Fig. 12.

The lead used in cupellation should be of the greatest purity, because, as most lead contains a small portion of silver, this silver would necessarily combine with the assay and vitiate the accuracy of the result. Another important consideration is the *quantity* of lead to be used with each assay. This information is generally obtained by an experimental assay, unless, as most frequently happens, the circumstances of the case enable the assayer to judge the approximate standard of the alloy with sufficient accuracy. The sample of gold alloy is either cut from a corner, or drilled out of the centre of an ingot, care being taken to secure uniformity of composition with the whole mass. The amount of lead to be added to the alloy varies with the proportion of base metal present; as a rule, from 10 to 20 parts are required to 1 of alloy.

The amount of lead having been determined, the alloy is wrapped up in a known quantity (say one-half of that required for its purification), formed into a case somewhat resembling a thimble, great care being taken to make the joints firm and close so that no gold shall escape. The requisite quantity of silver is added at the same time. When a number of assays are made at the same time, they are arranged, enveloped in their lead cases, on a board divided into compartments corresponding in number and position with the cupels into which they are intended to be charged. As the assayer generally makes two or more trials of the same piece, so that great accuracy may be secured, it is his practice to give one assay a side place in the muffle, and the second a middle one, in order to check any irregularity in the result. When a sufficient number of assays are weighed and arranged upon the board in the manner referred to, and the furnace as well as the cupels raised to the necessary point of heat, the charging tongs are then taken, and the rest of the lead and silver apportioned to each assay placed individually upon the cupels, beginning at the back of the muffle. The lead added in this case is not flattened, but is a piece of known weight—various sizes of which, as well as cases, are kept in stock by the assayer. The lead so placed in the furnace rapidly melts, and becomes covered with a gray oxide, but soon after appears fluid and bright. At this point the assays are added by means of a pair of tongs (fig. 13), great care being taken that no part overhangs or touches the edge of the cupel. The assays are thus drawn into the mass of molten lead, and any particles of gold are in this manner prevented from adhering to the sides of the cupels in charging, sufficient despatch being used to obviate the fusion of the assay in its transition. The assays being charged in order on their respective cupels, and the furnace previously filled with fuel, the door of the muffle is partly closed, and the progress of the cupellation watched. Too much air must not enter, or the muffle will be chilled and the progress retarded, whilst if too little enters the operation will be too slow.

Fig. 13.

At first dense fumes will be observed to rise from the melted metal, indicating the oxidation and subsequent volatilisation of the lead. These after continuing some time are followed by the appearance of small luminous points on the surface, which increase in size and brilliancy as the operation progresses. Then a minute stream of red fused oxide of lead is seen to flow from the top of the metal globule and circulate round, when it is carried down and absorbed by the cupel. This is caused by the oxidation of the lead by the air, which at the same time oxidises the other metals, except silver, which accompany the gold. As the cupellation advances the fumes gradually lessen in density till they disappear altogether. The melted button at this stage is observed to become more convex and round, and as the last vestiges of the lead and alloy are being carried off, it assumes a cloudy appearance on the surface, changing to large bright points of the fused oxide, till at length it is nearly freed from all impurity. At this point the gold-silver alloy displays some singular and beautiful characteristics. Deprived of all the base alloy save the last minute portion that tarnished its lustre, it has become bright and pure, and finally it gives forth from its surface iridescent circulating bands of light, which indicate the successful completion of the operation. The globules after being cooled, are removed from the cupels with a pair of pincers and carefully cleaned. They are then placed in their compartments and weighed with the greatest nicety. Finally, they are submitted to the operation of *parting*. This is effected by boiling with strong nitric acid, which dissolves the silver and leaves the gold as a sponge. The gold-silver globule is first passed through a flattening mill, and reduced to long thin strips, which are annealed and then rolled up into a corkscrew spiral, so that the acid may penetrate between each fold. The spirals are now transferred in order to small platinum cups arranged on a frame, so that they can be simultaneously lowered into and removed from the nitric acid. They are kept in the hot acid for the requisite time, then washed, and the residual gold sponge, which possesses considerable coherence, and retains the shape of the original spiral, is carefully dried and finally weighed with the greatest possible accuracy.

We shall now proceed to describe briefly the process of silver assay. The cupellation process does not differ except in details from that of gold,—the outline already given will, therefore, be a sufficient description. Like gold, silver occurs in two classes of combinations,—*mineralised*, as in *red silver ore*, *chloride of silver*, *argentiferous galena*, &c., or as *metallic silver* and its alloys. In metallurgical establishments, where silver occurs in small proportion with metallic sulphides, such as those of lead or copper, the process of cupellation is generally adopted not only for quantitative estimation of the amount of silver present in the ore. but also for its extraction on the large scale. In the assay of silver bullion. however, the process of cupellation is now almost entirely superseded by a volumetric process, devised by the distinguished French chemist, Gay-Lussac, by whose influence it was introduced into the Paris Mint. The process consists in determining the fineness of silver bullion by the quantity of a standard solution of common salt necessary to precipitate fully and exactly the silver contained in a known weight of alloy. This process is based on the following principles :—

The alloy previously dissolved in nitric acid is mixed with a standard solution of common salt, which precipitates the silver as chloride, a compound perfectly insoluble in water and even in acids. The quantity of chloride of silver precipitated is determined not by its weight, which would be less exact, and occupy too much time, but by the weight or volume of the standard solution of common salt necessary to precipitate exactly the silver previously dissolved in nitric acid. The term of complete precipitation of the silver can be readily recognised by the cessation of all cloudiness when the salt solution is gradually poured into that of the nitrate of silver. One milligramme of that metal is readily detected in 150 grammes of liquid, and even a half or a quarter of a milligramme may be detected if the liquid be perfectly bright before the addition of the salt solution. By violent agitation during a minute or two, the liquid, rendered milky by the precipitation of chloride of silver, becomes sufficiently bright after a few moments' repose to allow of the effect of the addition of half a milligramme of silver to be perceptible. Filtration of the liquid is more efficacious than agitation ; but the latter, which is much more rapid, generally suffices. The presence of copper, lead, or any other metal, with the exception of mercury in the silver solution, has no sensible influence on the quantity of salt required for precipitation ; in other words, the same quantity of silver, pure or alloyed, requires for its precipitation a constant quantity of the standard salt solution. Supposing that 1 gramme of pure silver be the quantity operated on, the solution of salt required to precipitate exactly the whole of the silver ought to be of such strength that, if it be measured by weight, it shall weigh exactly 100 grammes, or if by volume, 100 cubic centimetres. This quantity of salt solution is divided into 1000 parts, called thousandths. The standard of an alloy of silver is generally the number of thousandths of solution of salt necessary to precipitate the silver contained in a gramme of the alloy.

The operations of assaying depend for their accuracy on the perfection of the balance used to ascertain the weights of the metals taken, and the resulting globules. In a good assay balance three essentials are indispensable:—(1.) It should be quick in its action; (2.) It should be constant and uniform; (3.) It should be extremely sensitive and delicate, indicating the minutest shades of difference. Assay balances, as now constructed, are capable of indicating a difference of the ten-thousandth of a grain. For a description of the modern chemical balance, see article BALANCE. (W. C.)

ASSELYN, HANS, a celebrated Dutch painter, was born at Antwerp in 1610, and died at Amsterdam in 1660. He received instruction from Esaias Vandervelde, and distinguished himself particularly in landscape and animal painting, though his historical works and battle-pieces are also admired. He travelled much in France and Italy, and modelled his style greatly after Bamboccio (Peter Laer). He was one of the first Dutch painters who introduced a fresh and clear manner of painting landscapes in the style of Claude Lorraine, and his example was speedily followed by other artists. Asselyn's pictures were in high estimation at Amsterdam, and several of them are in the museums of that city. Twenty-four pieces of landscapes and ruins, which he painted in Italy, have been engraved by Perelle.

ASSEMANI, the name of a Syrian Maronite family of famous Orientalists.

(1.) JOSEPH SIMON, a Maronite of Mount Lebanon, was born in 1687. When very young he was sent to the Maronite college in Rome, and was transferred thence to the Vatican Library. In 1717 he was sent to Egypt and Syria to search for valuable MSS., and returned with about 150 very choice ones. The success of this expedition induced the Pope to send him again to the East in 1735, and he returned with a still more valuable collection. On his return he was made titular archbishop of Tyre and librarian of the Vatican Library. He instantly began to carry into execution most extensive plans for editing and publishing the most valuable MS. treasures of the Vatican. His two great works are the *Bibliotheca Orientalis Clementino-Vaticana rec. manuscr. codd. Syr., Arab., Pers., Turc., Hebr., Samarit., Armen., Æthiop., Græc., Ægypt., Iber., et Malab., jussu et munif. Clem.* XI., Romæ, 1719–28, nine vols. folio, and *Ephraemi Syri opera omnia quæ extant, Gr., Syr., et. Lat.*, 6 vols. folio, Rome, 1737–46. Of the *Bibliotheca* the first three vols. only were completed. The work was to have been in four parts—(1.) Syrian and allied MSS., orthodox, Nestorian, and Jacobite; (2.) Arabian MSS., Christian and Mahometan; (3.) Coptic, Æthiopic, Persian, and Turkish MSS.; and (4.) Syrian and Arabian MSS. not distinctively theological; only the first part was completed, but extensive preparations were made for the others. There is a German abridgement by A. F. Peiffer.

(2.) JOSEPH ALOYSIUS, brother of Joseph Simon, and professor of Oriental languages at Rome. He died in 1782. Besides aiding his brother in his literary labours, he published, in 1749–60, *Codex Liturgicus Ecclesiæ Universæ in xv. libris* (this is incomplete), and *Comment. de Catholicis sive Patriarchis Chaldæorum et Nestorianorum*, Rome, 1775.

(3.) STEPHEN EVODIUS, nephew of Joseph Simon and Joseph Aloysius, was the chief assistant of his uncle Joseph Simon in his work in the Vatican Library. He was titular archbishop of Apamea in Syria, and held several rich prebends in Italy. His literary labours were very extensive. His two most important works were a description of certain valuable MSS. in his *Bibliothecæ Mediceo-Laurentianæ et Palatinæ codd. manuscr. Orientalium Catalogus*, Flor. 1742, fol., and his *Acta SS. Martyrum Orientalium.* He made several translations from the Syrian, and in conjunction with his uncle, he began the *Bibliothecæ Apostol. Vatic. codd. manusc. Catal., in tres partes distributus.* Only three vols. were published, and the fire in the Vatican Library in 1768 consumed the manuscript collections which had been prepared for the continuation of the work.

(4.) SIMON, grandnephew of Joseph Simon, was born at Tripoli in 1752, and was professor of Oriental languages in Padua. He died in 1820. He is best known by his masterly detection of the literary imposture of Vella, which claimed to be a history of the Saracens in Syria.

ASSEN, a town of the Netherlands, capital of the province of Drenthe, containing 6836 inhabitants. It lies 16 miles south of Groningen, is connected with the Zuyder-Zee by the Smilder canal, has a considerable trade in corn and peats. There are a number of highly interesting tumuli in the neighbourhood, in which various relics have been found, which are now deposited in the museum at Leyden.

ASSENS, a town of Denmark, on the west coast of Fühnen, the ordinary port for the traffic between that island and Schleswig. In 1535 it was stormed by John of Ranzau, and afterwards plundered and dismantled; but its fortifications, of which traces are still to be found, were restored in 1628. Population, 3581. Long. 9° 55′ E., lat. 55° 15′ N.

ASSER, JOHN, or ASSERIUS MENEVENSIS, was born in Pembrokeshire, and educated in the monastery of St David's by the Archbishop Asserius, who, according to Leland, was his kinsman. Here he became a monk, and by his assiduous application soon acquired universal fame as a person of great abilities and profound learning. King Alfred, always a munificent patron of genius, about the year 880 sent for him to court, and made him his preceptor and companion. As a reward for his services, the king appointed him abbot of two or three different monasteries, and at last promoted him to the episcopal see of Sherborne, where he died in the year 910. He was, says Pits, a man of happy genius, wonderful modesty, extensive learning, and great integrity of life. He wrote the life of Alfred (*De Vita et Rebus Gestis Alfredi*), in 893, apparently for the use of his Welsh countrymen. The authenticity of this work was denied by Mr Wright (in his *Biographia Britannica Literaria*), who thought it was the production of some monk of St Neots about the end of the 10th century. In this, however, he has had few followers, and the work is generally believed to be Asser's, though somewhat interpolated. It was first published by Archbishop Parker at the end of Walsingham's *Hist. Lond.*, 1574. The best editions are those of Wise (8vo, Oxon., 1722), and of Thorpe in his edition of *Florence of Worcester* for the English Historical Society. An English translation is to be found in Bohn's *Antiquarian Library.*

ASSESSOR, among the Romans, was a term generally applied to a trained lawyer who sat beside a governor of a province or other magistrate, to instruct him in the administration of the laws. The system is still exemplified in Scotland, where it is usual in the larger towns for municipal magistrates, in the administration of their civil jurisdiction, to have the aid of professional assessors. In municipal corporations in England, officers with the same name are appointed to assist at the election of councillors and ascertain the result. By the recent English Judicature Act, provision is made for trial of matters of fact by the judge with assessors instead of by jury, when parties so desire.

ASSETS, a technical English law word, derived through the old Norman phraseology from the same source as the French *assez*, enough, and signifying the property of a debtor available for the satisfaction of his creditors. Thus the property of a bankrupt is termed his *assets*, and is the fund out of which his liabilities must be paid. When a person dies, the goods which come to executors or administrators are called assets *personal;* the lands descending to the heir, are assets *real*. The former are the primary and natural fund out of which the debts of the testator or intestate of every description must be paid. The latter, by 3 and 4 Will. IV. c. 104, are also available, after the personal estate is exhausted, and preference is given to creditors by specialty over creditors by simple contract When one of two claimants may go to either fund, and the other is restricted to one fund only, if the first claimant has recourse to the fund open to both, equity will permit the other claimant to stand in the place of the first against the other fund. This is called *marshalling the assets.* If, for example, before the statute 3 and 4 Will. IV. c. 104, a special creditor, who might claim against either the real or the personal assets, satisfied his debt out of the latter, a creditor by simple contract, having the latter only to claim against, would be permitted to stand in place of the specialty creditor against the real estate.

ASSIDEANS, in Greek Ἀσιδαῖοι, is a transcription of the Hebrew *chasîdîm, pious ones*, a word frequent in the Psalms (xxxvii. 28, lxxix. 2, &c.,—E.V. generally *saints*). In the first book of Maccabees the name of Assideans appears as the designation of a society of men zealous for the law (1 Mac. ii. 42, according to the correct text as given by Fritzsche), and closely connected with the scribes (1 Mac. vii. 12, 13). It is plain from these passages that this society of "pious ones," who held fast to the law under the guidance of the scribes in opposition to the "godless" Hellenising party, was properly a religious, not a political organisation. For a time they joined the revolt against the Seleucids. But the direct identification of the Assideans with the Maccabee party in 2 Mac. xiv. 6 is one of the many false statements of that book, and directly contradictory to the trustworthy narrative of 1 Mac. vii., which shows that they were strictly a religious party, who scrupled to oppose the legitimate high priest even when he was on the Greek side, and who withdrew from the war of freedom as soon as the attempt to interfere with the exercise of the Jewish religion was given up. Under the Asmonean rule the Assideans developed into the better known party of the Pharisees, and assumed new relations to the ruling dynasty. It appears, however, from the *Psalter of Solomon* that the party continued to affect the title of "pious ones." Most recent inquirers hold that the Essenes as well as the Pharisees sprung from the Assideans (Ewald's *Geschichte*, vol. iv.; Wellhausen, *Die Pharisäer und die Sadducäer*, 1874).

ASSIGNMENT, Assignation, Assignee, are terms which, as derivatives of the verb assign, are of frequent technical use in the law of the different parts of the United Kingdom. To assign is to make over, and the term is generally used to express a transference by writing, in contradistinction to a transference by actual delivery. In England the usual expression is assignment, in Scotland it is assignation. The person making over is called the *assignor* or *cedent;* the recipient, the *assign* or *assignee.*

ASSISI (ancient *Asisium*), a city of Italy in the province of Perugia. It contains about 6000 inhabitants, depending chiefly for subsistence on the devotees, who, to the number of many thousands, make annual pilgrimages to the church which contains the tomb and bears the name of St Francis, the founder of the Franciscan order, who was born at Assisi in 1182. (See Francis, St.) This building is in the Pointed style, and was erected between the years 1228–30 It is attributed by Vasari to a German architect, and by its historian, Pietro Ridolfi, it is called Opus Teutonicum (Hope, *On Architecture*, vol. i.) The remains of an ancient temple of Minerva stand in the market-place, composed of six Corinthian pillars of fine proportions, and now forming the portico of Santa Maria de Minerva; and there are several churches of considerable artistic importance. The poet Metastasio was born here in 1698. Long. 12° 24′ 50″ E., lat. 43° 4′ 22″ N.

ASSIZE or Assise (from *assideo*, to sit together; Old French, *assire*, to set, *assis*, seated), literally signifies a "session," but is, in fact, as Littleton has styled it, a *nomen æquivocum*, meaning sometimes a jury, sometimes the sittings of a court, and sometimes the ordinances of a court or assembly.

1. It signified the form of trial by a jury of sixteen persons, which eventually superseded the barbarous judicial combat; this jury was named the Grand Assize. The Grand Assize was abolished by 3 and 4 Will. IV. c. 27; but the term assize is still applicable to the jury in criminal causes in Scotland.

2. In the only sense in which the word is not now almost obsolete, assize means the periodical session of the judges of the superior courts of Common Law, held in the various counties of England, chiefly for the purposes of gaol delivery and trying causes at *Nisi Prius.* Previous to Magna Charta (1215) writs of assize had all to be tried at Westminster, or to await trial in the locality in which they had originated at the septennial circuit of the justices in eyre; but, by way of remedy for the great consequent delay and inconvenience, it was provided by this celebrated Act that the assizes of *mort d'ancestor* and *novel disseisin* should be tried annually by the judges in every county. By successive enactments, the civil jurisdiction of the justices of assize was extended, and the number of their sittings increased, till at last the necessity of repairing to Westminster for judgment in civil actions was almost obviated to county litigants by an Act, passed in the reign of Edward I., which provided that the writ summoning the jury to Westminster should also appoint a time and place for hearing such causes within the county of their origin. The date of the alternative summons to Westminster was always subsequent to the former date, and so timed as to fall in the vacation preceding the Westminster term; and thus "*Unless before,*" or *Nisi Prius*, issues came to be dealt with by the judges of assize before the summons to Westminster could take effect. The *Nisi Prius* clause, however, was not then introduced for the first time. It occurs occasionally in writs of the reign of Henry III. The Royal Commissions to hold the assizes are—(1.) General, (2.) Special. The General Commission is issued twice a year to the superior courts of Common Law at Westminster, and two judges are generally sent on each circuit. It covers commissions—(1.) of *oyer* and *terminer;* (2.) of Nisi Prius; (3.) of gaol delivery; (4.) of the peace. Special commissions are granted for inquest in certain causes and crimes.

3. Assizes, in the sense of ordinances or enactments of a court or council of state, are of considerable interest in our earlier economic history. As early as the reign of John the observance of the *assisæ venalium* was enforced, and for a period of five hundred years thereafter it was considered no unimportant part of the duties of the legislature to regulate by fixed prices, for the protection of the lieges, the sale of bread, ale, fuel, &c. Sometimes in city charters the right to assize such articles is specially conceded. Regulations of this description, though hostile to free trade, were beneficial in the repression of fraud and adulteration.

4. Assizes are sometimes used in a wider legislative connection by early chroniclers and historians,—the "assisæ of the realme," *e.g.*, occasionally meaning the organic laws of the country. In a still more extended sense, the "Assizes of Jerusalem" is the name given to the code of laws framed for the kingdom of Jerusalem at the instance of Godfrey of Bouillon, the Crusader.

ASSOCIATION OF IDEAS, or MENTAL ASSOCIATION, is a general name used in psychology to express the conditions under which representations arise in consciousness, and also is the name of a principle of explanation put forward by an important school of thinkers to account generally for the facts of mental life. The more common expression, from the time of Locke, who seems to have first employed it, has been Association of Ideas; but it is allowed or urged on all hands that this phrase contains too narrow a reference; association, in either of the senses above noted, extending beyond ideas or thoughts proper to every class of mental states. In the long and erudite Note D**, appended by Sir W. Hamilton to his edition of *Reid's Works*, and offered as a contribution towards a history of the doctrine of mental suggestion or association, many anticipations of modern statements are cited from the works of ancient or mediæval thinkers, and for Aristotle, in particular, the glory is claimed of having at once originated the doctrine and practically brought it to perfection. Aristotle's enunciation of the doctrine is certainly very remarkable. As translated by Hamilton, but without his interpolations, the classical passage from the tract *De Memoria et Reminiscentia* runs as follows :—

"When, therefore, we accomplish an act of reminiscence, we pass through a certain series of precursive movements, until we arrive at a movement on which the one we are in quest of is habitually consequent. Hence, too, it is that we hunt through the mental train, excogitating from the present or some other, and from similar or contrary or coadjacent. Through this process reminiscence takes place. For the movements are, in these cases, sometimes at the same time, sometimes parts of the same whole, so that the subsequent movement is already more than half accomplished."

The passage is obscure (leaving open to Hamilton to suggest a peculiar interpretation of it, that may be noticed in connection with the elaborate doctrine of association put forward by himself, as if to evince the shortcomings rather than the perfection of Aristotle's), but it does in any case indicate the various principles commonly termed Contiguity, Similarity, and Contrast; and, though the statement of these cannot be said to be followed up by an effective exposition or application, it quite equals in scope the observations of many a modern inquirer. Zeno the Stoic also, and Epicurus, according to the report of Diogenes Laertius (vii. § 52, x. § 32, overlooked by Hamilton), enumerated similar principles of mental association. By St Augustin, at the end of his long rhapsody on the wonders of memory in book x. of his *Confessions*, it was noted (c. 19) that the mind, when it tries to remember something it knows it has forgotten, has, as it were, hold of part and thence makes quest after the other part. Meanwhile and later, Aristotle's doctrine received a more or less intelligent expansion and illustration from the ancient commentators and the schoolmen; and in the still later period of transition from the age of scholasticism to the time of modern philosophy, prolonged in the works of some writers far into the 17th century, Hamilton, from the stores of his learning, is able to adduce not a few philosophical authorities who gave prominence to the general fact of mental association—the Spaniard Ludovicus Vives (1492–1540) especially being most exhaustive in his account of the conditions of memory. This act of justice, however, once rendered to earlier inquirers, it is to modern views of association that attention may fairly be confined.

In Hobbes's psychology so much importance is assigned to what he called, variously, the succession, sequence, series, consequence, coherence, train, &c., of imaginations or thoughts in mental discourse, that he has not seldom been regarded, by those who did not look farther back, as the founder of the theory of mental association. He did, indeed, vividly conceive and illustrate the principle of Contiguity, but, as Hamilton conclusively shows, he reproduced in his exposition but a part of the Aristotelian doctrine, nor even this without wavering; representing the sequence of images, in such states as dreams, now (in his *Human Nature*) as casual or incoherent, now (in *Leviathan*), following Aristotle, as simply unguided. Not before Hume, among the moderns, is there express question as to a number of distinct principles of association. Locke had, meanwhile, introduced the phrase Association of Ideas as the title of a supplementary chapter incorporated with the fourth edition of his *Essay*, meaning it, however, only as the name of a principle accounting for the mental peculiarities of individuals, with little or no suggestion of its general psychological import. Of this last Hume had the strongest impression, and thinking himself, in forgetfulness or ignorance of Aristotle's doctrine of reminiscence, the first inquirer that had ever attempted to enumerate all the modes of normal association among mental states, he brought them to three—Resemblance, Contiguity in time and place, Cause and (or) Effect. Without professing to arrive at this result otherwise than by an inductive consideration of instances, he yet believed his enumeration to be exhaustive, and sought to prove it so by resolving Contrast—one of Aristotle's heads, commonly received—as a mixture of causation and resemblance. Viewed in relation to his general philosophical position, it must always remain a perplexing feature of Hume's list of principles, that he specified Causation as a principle distinct from Contiguity in time, while otherwise the list has no superiority to Aristotle's. Hume's fellow-countrymen, Gerard and Beattie, in opposition to him, recurred accordingly to the traditional enumeration; and, in like manner, Dugald Stewart put forward Resemblance, Contrariety, and Vicinity in time and place, though he added, as another obvious principle, accidental coincidence in the sounds of Words, and farther noted three other cases of relation, namely, Cause and Effect, Means and End, and Premisses and Conclusion, as holding among the trains of thought under circumstances of special attention. Reid, preceding Stewart, was rather disposed, for his own part, to make light of the subject of association, vaguely remarking that it seems to require no other original quality of mind but the power of habit to explain the spontaneous recurrence of trains of thinking, when become familiar by frequent repetition (*Intellectual Powers*, p. 387). The counter-observation of his editor, Hamilton, that we can as well explain habit by association as association by habit, might with reason have been pointed more sharply.

Hamilton's own theory of mental reproduction, suggestion, or association, given in outline in Note D***, following the historical note before mentioned, at the end of his edition of *Reid's Works*, calls for more special notice, as perhaps the most elaborate expression yet devised for the principles involved in the phenomena of mental representation. It is a development, greatly modified, of the doctrine expounded in his *Lectures on Metaphysics* (vol. ii. p. 223, *seq.*), which in agreement with some foreign authorities, reduced the principles of association first to two—Simultaneity and Affinity, and these farther to one supreme principle of Redintegration or Totality. In the ultimate scheme he posits no less than four general laws of mental succession concerned in reproduction: (1.) Associability or possible co-suggestion (all thoughts of the same mental subject are associable, or capable of suggesting each other); (2.) Repetition or direct remembrance (thoughts coidentical in modification, but differing in time, tend to suggest each other); (3.) Redintegration, direct remembrance or reminiscence (thoughts once coidentical in time, are, however, different as mental modes, again suggestive of each other, and that in the mutual order which they originally held); (4.) Preference (thoughts are suggested not merely by force of the general subjective relation subsisting between themselves, they are also suggested in proportion to the relation of interest, from whatever source, in which they stand to the individual mind) Upon these follow, as special laws:—A, Primary—modes of the laws of Repetition and Redintegration—(1), law of Similars (Analogy, Affinity); (2), law of Contrast; (3), law of Coadjacency (Cause and Effect, &c.); B, Secondary—modes of the law of Preference, under the law of Possibility—(1), laws of Immediacy and Homogeneity; (2), law of Facility. Such is the scheme; and now may be understood what interpretation Hamilton desires to put upon Aristotle's doctrine, when he finds or seeks in it a parallel relation to that established by himself between the general laws, more especially Redintegration, and his special ones. But, though the commentary of Themistius, which he cites, lends some kind of support to the position, it cannot be maintained without putting the greatest strain on Aristotle's language, and in one place it is as good as surrendered by Hamilton himself (footnote, p. 900, *b*). Nor is the ascription of such a meaning at all necessary to establish Aristotle's credit as regards the doctrine of mental association.

Thus far the principles of association have been considered only as involved in mental reproduction and representation. There has grown up, however, especially in England, the psychological school above mentioned, which aims at explaining all mental acquisitions, and the more complex mental processes generally, under laws not other than those determining simple reproduction. Hamilton also, though professing, in the title of his outline just noticed, to deal with reproduction only, formulates a number of still more general laws of mental succession—law of Succession, law of Variation, law of Dependence, law of Relativity or Integration (involving law of Conditioned), and, finally, law of Intrinsic or Objective Relativity—as the highest to which human consciousness is subject; but it is in a sense quite different that the psychologists of the so-called Associationist School intend their appropriation of the principle or principles commonly signalised. As far as can be judged from imperfect records, they were anticipated to some extent by the experientialists of ancient times, both Stoic and Epicurean (*cf.* Diogenes Laertius, as above). In the modern period, Hobbes is the first thinker of permanent note to whom the doctrine may be traced. Though he took, as has been seen, anything but an exhaustive view of the phenomena of mental succession, yet, after dealing with trains of imagination, or what he called mental discourse, he sought in the higher departments of intellect to explain reasoning as a discourse in words, dependent upon an arbitrary system of marks, each associated with, or standing for, a variety of imaginations; and, save for a general assertion that reasoning is a reckoning—otherwise, a compounding and resolving—he had no other account of knowledge to give. The whole emotional side of mind, or, in his language, the passions, he, in like manner, resolved into an expectation of consequences based on past experience of pleasures and pains of sense. Thus, though he made no serious attempt to justify his analysis in detail, he is undoubtedly to be classed with the associationists of the next century—Hartley and the others. They, however, were wont to trace the first beginnings of their psychological theory no farther back than to Locke's *Essay*. If this seems strange, when Locke did little more than supply them with the word Association, it must be remembered in what ill repute the name of Hobbes stood, and also that Locke's work, though not directly concerned with the question of psychological development, being rather of metaphysical or logical import, was eminently psychological in spirit, and might fairly be held to contain in an implicit form the principle or principles evolved later by the associationists. Berkeley, dealing, immediately after Locke and altogether in Locke's spirit, with the special psychological problem of visual perception, was driven to posit expressly a principle of suggestion or association in these terms:—"That one idea may suggest another to the mind, it will suffice that they have been observed to go together, without any demonstration of the necessity of their coexistence, or so much as knowing what it is that makes them so to coexist" (*New Theory of Vision*, § 25); and to support the obvious application of the principle to the case of the sensations of sight and touch before him, he constantly urged that association of sound and sense of language which the later school has always put in the foreground, whether as illustrating the principle in general or in explanation of the supreme importance of language for knowledge. It was natural, then, that Hume, coming after Berkeley, and assuming Berkeley's results, though he reverted to the larger inquiry of Locke, should be more explicit in his reference to association; and, not only explicit, he was original also, when he spoke of it as a "kind of attraction which in the mental world will be found to have as extraordinary effects as in the natural, and to show itself in as many and as various forms" (*Human Nature*, i. 1, § 4). Other inquirers were, in fact, appearing about the same time, who conceived of association with this breadth of view, and set themselves to track, as psychologists, its effects in detail.

Hartley's *Observations on Man*, published in 1749 (eleven years after the *Human Nature*, and one year after the better-known *Inquiry*, of Hume), opened the path for all the investigations of like nature that have since that time become so characteristic of the English name in psychology. According to his own statement, his attention was first turned to the subject about eighteen years before, through what he heard of an opinion of the "Rev. Mr Gay," that it was possible to deduce all our intellectual pleasures and pains from association. Gay is known only by a dissertation on the fundamental principles of virtue, prefixed, at first anonymously, in 1731, to Archdeacon (afterwards Bishop) Law's translation of King's *Origin of Evil*, wherein it was maintained, with considerable force, that by association the feelings belonging to ends may come to attach themselves to means, and give rise to action for the means as if they were ends, as seen (the instance has become a commonplace) in the passion for money-making. In this vein, but on a very different scale, Hartley proceeded to work. A physician by profession, and otherwise well versed in science, he sought to combine with an elaborate theory of mental association a minutely detailed hypothesis as to the corresponding action of the nervous system, based upon the suggestion of a vibratory motion within the nerves thrown out by Newton in the last paragraph of the *Principia*. So far, however, from promoting the acceptance of the psychological theory, this physical hypothesis proved to have rather the opposite effect, and it began to be dropped by Hartley's followers (as Priestley, in his abridged edition of the *Observations*, 1775) before it was seriously impugned from without. When it is studied in the original, and not taken upon the report of hostile critics, who would not, or could not—at all events, who did not—understand it, no little importance must still be accorded to, the first attempt, not seldom a curiously felicitous one, to carry through that parallelism of the physical and psychical, which since then has come to count for more and more in the science of mind. Nor should it be forgotten that Hartley himself, for all his paternal interest in the doctrine of vibrations, was careful to keep separate from its fortunes the cause of his other doctrine of mental association. Of this the point lay in no mere restatement, with new precision, of a principle of coherence among "ideas," but in its being taken as a clue by which to follow the progressive development of the mind's powers. Holding that mental states could be scientifically understood only as they were analysed, Hartley sought for a principle of synthesis to explain the complexity exhibited not only in trains of representative images, but alike in the most involved combinations of reasonings and (as Berkeley had seen) in the apparently simple phenomena of objective perception, as well as in the varied play of the emotions, or, again, in the manifold conscious adjustments of the motor system. One principle appeared to him sufficient for all, running, as enunciated for the simplest case, thus: "Any sensations A, B, C, &c., by being associated with one another a sufficient number of times, get such a power over the corresponding ideas (called by Hartley also vestiges, types, images) *a*, *b*, *c*, &c., that any one of the sensations A, when impressed alone, shall be able to excite in the mind *b*, *c*, &c., the ideas of the rest." To render the principle applicable in the cases where the associated elements are neither sensations nor simple ideas of sensations, Hartley's first care was to determine the conditions under which states other than these simplest ones have their rise in the mind, becoming the matter of ever higher and higher combinations. The principle itself supplied the key to the difficulty, when coupled with the notion, already implied in Berkeley's investigations, of a coalescence of simple ideas of sensation into one complex idea, which may cease to bear any obvious relation to its constituents. So far from being content, like Hobbes, to make a rough generalisation to all mind from the phenomena of developed memory, as if these might be straightway assumed, Hartley made a point of referring them, in a subordinate place of their own, to his universal principle of mental synthesis. He expressly put forward the law of association, endued with such scope, as supplying what was wanting to Locke's doctrine in its more strictly psychological aspect, and thus marks by his work a distinct advance on the line of development of the experiential philosophy.

The new doctrine received warm support from some, as Law and Priestley, who both, like Hume and Hartley himself, took the principle of association as having the like import for the science of mind that gravitation had acquired for the science of matter. The principle began also, if not always with direct reference to Hartley, yet, doubtless, owing to his impressive advocacy of it, to be applied systematically in special directions, as by Tucker (1768) to morals, and by Alison (1790) to æsthetics. Thomas Brown (d. 1820) subjected anew to discussion the question of theory. Hardly less unjust to Hartley than Reid or Stewart had been, and forward to proclaim all that was different in his own position, Brown must yet be ranked with the associationists before and after him for the prominence he assigned to the associative principle in sense-perception (what he called external affections of mind), and for his reference of all other mental states (internal affections) to the two generic capacities or susceptibilities of Simple and Relative Suggestion. He preferred the word Suggestion to Association, which seemed to him to imply some prior connecting process, whereof there was no evidence in many of the most important cases of suggestion, nor even, strictly speaking, in the case of contiguity in time where the term seemed least inapplicable. According to him, all that could be assumed was a general constitutional tendency of the mind to exist successively in states that have certain relations to each other, of itself only, and without any external cause or any influence previous to that operating at the moment of the suggestion. Brown's chief contribution to the general doctrine of mental association, besides what he did for the theory of perception, was, perhaps, his analysis of voluntary reminiscence and constructive imagination—faculties that appear at first sight to lie altogether beyond the explanatory range of the principle. In James Mill's *Analysis of the Phenomena of the Human Mind* (1829), the principle, much as Hartley had conceived it, was carried out, with characteristic consequence, over the psychological field. With a much enlarged and more varied conception of association, Professor Bain has re-executed the general psychological task in the present generation, while Mr Herbert Spencer has revised the doctrine from the new point of view of the evolution-hypothesis. John Stuart Mill made only occasional excursions into the region of psychology proper, but sought, in his *System of Logic* (1843), to determine the conditions of objective truth from the point of view of the associationist theory, and, thus or otherwise being drawn into general philosophical discussion, spread wider than any one before him its repute.

It is remarkable that the Associationist School has been composed chiefly of British thinkers, but in France also it has had distinguished representatives. Of these it will suffice to mention Condillac, the author of the sensationalist movement in the 18th century, who professed to explain all knowledge from the single principle of association (*liaison*) of ideas, operating through a previous association with signs, verbal or other. At the present day the later English school counts important adherents among the younger French thinkers. In Germany, before the time of Kant, mental association was generally treated in the traditional manner, as by Wolff. Kant's inquiry into the foundations of knowledge, agreeing in its general purport with Locke's, however it differed in its critical procedure, brought him face to face with the newer doctrine that had been grafted on Locke's philosophy; and to account for the fact of synthesis in cognition, in express opposition to associationism, as represented by Hume, was, in truth, his prime object, starting, as he did, from the assumption that there was that in knowledge which no mere association of experiences could explain. To the extent, therefore, that his influence prevailed, all such inquiries as the English associationists went on to prosecute were discounted in Germany. Notwithstanding, under the very shadow of his authority a corresponding, if not related, movement was initiated by Herbart. Peculiar, and widely different from anything conceived by the associationists, as Herbart's metaphysical opinions were, he was at one with them, and at variance with Kant, in assigning fundamental importance to the psychological investigation of the development of consciousness, nor was his conception of the laws determining the interaction and flow of mental presentations and representations, when taken in its bare psychological import, essentially different from theirs. In Beneke's psychology also, and in more recent inquiries conducted mainly by physiologists, mental association has been understood in its wider scope, as a general principle of explanation.

Associationists differ not a little among themselves in the statement of their principle, or, when they adduce several principles, in their conception of the relative importance of these. Hartley took account only of Contiguity, or the repetition of impressions synchronous or immediately successive; and the like is true of James Mill, though, incidentally, he made an express attempt to resolve the received principle of Similarity, and through this the other principle of Contrast, into his fundamental law—law of Frequency, as he sometimes called it, because upon frequency, in conjunction with vividness of impressions, the strength of association, in his view, depended. In a sense of his own, Brown also, while accepting the common Aristotelian enumeration of principles, inclined to the opinion that "all suggestion may be found to depend on prior coexistence, or at least on such proximity as is itself very probably a modification of coexistence," provided account be taken of "the influence of emotions and other feelings that are very different from ideas, as when an analogous object suggests an analogous object by the influence of an emotion which each separately may have produced before, and which is, therefore, common to both." (Upon which view it obviously occurs to remark, that, except in the particular case, plainly not intended, where the objects are experienced in actual succession with the emotion common to both, a suggestion through *similar* emotions must still be presumed.) To the contrary effect, Mr Spencer maintains that the fundamental law of all mental association is that presentations aggregate or cohere with their like in past experience, and that, besides this law, there is in strictness no other, all further phenomena of association being incidental. Thus in particular, he would explain association by Contiguity as due to the circumstance of imperfect assimilation of the present to the past in consciousness; a presentation in as far as it is distinctly cognised is in fact recognised through cohering with its like in past experience, but there is always, in consequence of the imperfection of our perceptions, a certain range within which the classing of the present experience with past is doubtful—a certain cluster of relations nearly like the one perceived, which become nascent in consciousness in the act of assimilation; now contiguity is likeness of relation in time or in space, or in both, and, when the classing, which, as long as it is general, goes easily and infallibly forward, becomes specific, a presentation may well arouse the merely contiguous, instead of the identical, from former experience. Midway between these opposed views should be noted, finally, the position of Professor Bain, who regards Contiguity and Similarity, logically, as perfectly distinct principles, though in actual psychological occurrence they blend intimately with each other; contiguous trains being started by a first (it may be, implicit) representation through Similarity, while the express assimilation of present to past in consciousness is always, or tends to be, followed by the revival of what was presented in contiguity with that past.

That Similarity is an ultimate ground of mental association cannot seriously be questioned, and to neglect or discount it, in the manner of the older representatives of the school, is to render the associationist theory quite inadequate for purposes of general psychological explanation. It is simply impossible to over-rate the importance of the principle, and, when Mr Spencer, by way of supporting his position, maintains farther, that the psychological fact of conscious assimilation corresponds with the fundamentally simple physiological fact of re-excitation of the same nervous structures, the force as well as pertinence of the observation is at once evident. Nevertheless, it is one question whether a representation, upon a particular occasion, shall be evoked by Similarity, and another question what shall be raised into consciousness along with it; nor for this is there any help but in positing a distinct principle of Contiguity. The phenomena of presentative cognition or objective perception on which Mr Spencer bases his argument, are precisely those in which the function of Contiguity is least explicitly manifested, but only because of the certainty and fixity it has assumed through the great uniformity and frequency of such experience. Let the series of presentative elements, as in formal education, be less constant in composition, and less frequently recurrent, than are those aggregates of sensible impressions that, in the natural course of experience, become to us objects in space with a character comparatively fixed, and then the function of Contiguity starts out with sufficient prominence, being found as often as not to fail in determining a revival of the corresponding representative series. All the phenomena, too, of coalescence, in which a variety of elements become fused to a result in consciousness as heterogeneous as any chemical compound in relation to its constituents—phenomena that have remained the very property of the Associationist School since they first were distinctly noted by Hartley—how are these to be explained by the principle of Similarity? Involved as it incontestably is in every repeated apprehension, whether of the elements, or of the product, or of the relation between them, Similarity of itself is powerless to determine a relation the essence of which lies not more in the heterogeneous character of the result than in the diversity of the elements brought together. Nor, in order to support the claim of the principle of Contiguity to an equally fundamental position with that of Similarity, is it more difficult to find an expression in terms of physiology corresponding with the subjective process. The fact that different nerve-centres are excited together, synchronously or successively, along definite lines of connection, will leave them, being so connected, in a state of relative instability, which, other things equal, will vary in proportion to the frequency and strength of the excitation; and thus, when one of them is, in whatever way, again aroused, the rest will tend to be re-affected also by reason of the instability that has remained. The process of psychological representation, running parallel with the nervous events here supposed, involves assimilation at every stage from and including the first; it is also constantly happening, in contiguous trains, that a break occurs at a particular stage through an express suggestion, by Similarity, of something foreign to the train. But in the one case, as in the other—alike coincident with the implicit action of Similarity, and in the pauses of express assimilation—the principle of Contiguity has a part to play, not to be denied or confounded with any other.

A minor question, also disputed, is whether by the side of Contiguity and Similarity, Contrast should be held, as by Aristotle, an independent principle of association. That things contrasted may and do often suggest each other in consciousness is on all hands allowed, but ever since Hume attempted, however infelicitously, to resolve the principle into others, its independence has not ceased to lie under suspicion. When the question is approached without prejudice, it cannot but appear strange that mental states which suggest each other because of likeness, should suggest each other because of unlikeness also. In that case anything might suggest everything else, since like and unlike conscious states are all that are possible; nay, unlike states alone are all, as there must always be some difference between any two. Now it is true, in one sense, that anything may suggest anything be it ever so unlike, namely, if the things have been once or repeatedly experienced in conjunction; but then the bond of association is the contiguity, and not the unlikeness, which obviously cannot be a ground for suggesting this one other thing more than any other thing. By contrast, however, is not generally meant bare unlikeness. Genuine contrasts, as black-white, giant-dwarf, up-down, are peculiar in having under the difference a foundation of similarity, the two members lying within the sphere of a common higher notion, and only being distinguished the more impressively by reason of the accompanying unlikeness. Clearly, in the case of mutual suggestion, if it be not the similarity itself that is here the ground of association, it may again be Contiguity, the sharpest experience of each member of the contrast having been when there was experience also of the other; or both grounds may conspire towards the result, the association being then what Professor Bain has marked as Compound. On the whole, it must be concluded that only in a secondary sense can Contrast be admitted as a principle of mental association.

The highest philosophical interest, as distinguished from that which is more strictly psychological, attaches to the mode of mental association called Inseparable. The coalescence of mental states noted by Hartley, as it had been assumed by Berkeley, was farther formulated by James Mill in these terms:—

"Some ideas are by frequency and strength of association so closely combined that they cannot be separated; if one exists, the other exists along with it in spite of whatever effort we make to disjoin them."—(*Analysis of the Human Mind*, 2d ed. vol. i. p. 93.)

J. S. Mill's statement is more guarded and particular:—

"When two phenomena have been very often experienced in conjunction, and have not, in any single instance, occurred separately either in experience or in thought, there is produced between them what has been called inseparable, or, less correctly, indissoluble, association; by which is not meant that the association must inevitably last to the end of life—that no subsequent experience or process of thought can possibly avail to dissolve it; but only that as long as no such experience or process of thought has taken place, the association is irresistible; it is impossible for us to think the one thing disjoined from the other."—(*Examination of Hamilton's Philosophy*, 2d ed. p. 191.)

Even this statement, however, is somewhat lacking in precision, since there never is any impossibility of thinking the things apart, in the sense of considering them as logically distinct; the very fact of association implies at least such distinctness, while there may be evident, besides, a positive difference of psychological origin, as when, in the case of visual extension, the colour of the field is referred to the passive sensibility of the eye, and the expanse to its mobility. The impossibility is of representation apart, not of logical consideration or thought. It is chiefly by J. S. Mill that the philosophical application of the principle has been made. The first and most obvious application is to so-called necessary truths—such, namely, as are not merely analytic judgments but involve a synthesis of distinct notions. Again, the same thinker has sought, in the work just cited, to prove Inseparable Association the ground of belief in an external objective world. The former application, especially, is facilitated, when the experience through which the association is supposed to be constituted is understood as cumulative in the race, and transmissible as original endowment to individuals—endowment that may be expressed either, subjectively, as latent intelligence, or, objectively, as fixed nervous connections. Mr Spencer, as before suggested, is the author of this extended view of mental association.

For a detailed exposition of the psychological theory of the Associationist School, the reader is referred to the works of its latest representatives named above. The question is still under discussion, how far the theory avails to account for the facts of intelligence, not to say the complex phases of mental life in general in all their variety; nor, were the theory carried out farther than it has yet been by any one, and formulated in terms commanding more general assent than any expression of it has yet obtained even from professed adherents, is it likely to be raised above dispute. Yet it must be allowed to stand forward with a special claim to the scientific character; as already in his time Laplace (who, though an outsider, could well judge) bore witness, when, speaking of the principle of association (Contiguity) as applied to the explanation of knowledge, he declared it *la partie réelle de la métaphysique* (*Essai phil. sur les Probabilités, Œuvres,* vol. vii. p. cxxxvii.) If in the physical sciences the object of the inquirer is confined to establishing laws expressive of the relations subsisting amongst phenomena, then, however different be the internal world of mind—however short such treatment may seem to come of expressing the depth and fulness even of its phenomenal nature—a corresponding object is as much as the scientific psychologist can well set to himself. The laws of association express undoubted relations holding among particular mental states, that are the real or actual facts with which the psychologist has to deal, and it becomes a strictly scientific task to inquire how far the whole complexity of the internal life may receive an explanation therefrom. Understood in this sense, Hume's likening of the laws of mental association to the principle of gravitation in external nature is perfectly justifiable. It is to the credit of the associationists to have grasped early, and steadily maintained, such a conception of psychological inquiry, and, whatever their defects of execution may have been or remain, their work retains a permanent value as a serious attempt to get beyond barren description of abstract mental faculties to real and effective explanation. The psychologists that, in the related point of view, have earned the title of the Analytical School, from holding before their eyes the exemplar of the method of the positive sciences, are precisely those that have fastened upon the principles of association as the ground of mental synthesis; and, till it is shown that the whole method of procedure is inapplicable to such a subject as mind, their conception is entitled to rank as a truly scientific one. (G. C. R.)

ASSUAY, formerly the most southern department of Ecuador, in South America. It is now broken up into the two provinces of Cuença and Loxa. Cuença, Loxa, Jaca, and Borga, were its principal towns. Its chief productions were cinchona bark and silver.

ASSUMPTION, a festival of the Christian church, observed on the 15th August, in honour of the miraculous ascent of the Virgin Mary into heaven. It rests upon a purely traditional account of the ascent, first recorded by Gregory of Tours. Its present place in the calendar was fixed early in the 8th century. The Roman and Greek Churches both celebrate this festival.

ASSYRIA. The two great empires which grew up on the banks of the Tigris and Euphrates can be separated as little historically as geographically. It is proposed, therefore, to treat both under the heading BABYLONIA. From the beginning their history is closely intertwined; and the power of the one is a measure of the weakness of the other. This interdependence of Assyrian and Babylonian history was recognised by ancient writers, and has been confirmed by modern discovery. But whereas Assyria takes the first place in the classical accounts to the exclusion of Babylonia, the decipherment of the inscriptions has proved that the converse was really the case, and that, with the exception of some six or seven centuries, Assyria might be described as a province or dependency of Babylon. Not only was Babylonia the mother country, as the tenth chapter of Genesis explicitly states, but the religion and culture, the literature and the characters in which it was contained, the arts and the sciences of the Assyrians were derived from their southern neighbours. Both had the same population and spoke the same language. In accordance, therefore, with the evidence of the native monuments, Assyria will be treated in connection with Babylonia. With all the similarity, however, there were, of course, certain differences in the character and development of the two countries. These differences will be carefully noted, and subjects which peculiarly belong to either the one or the other empire will be fully and separately dealt with. (See BABYLONIA.)

AST, George Anthony Frederick, a German philosopher and philologist of considerable distinction, was born at Gotha in 1778. He was educated at the gymnasium of that town, and afterwards at the university of Jena. He distinguished himself as a student, and in 1802 he became a privat-docent in his alma mater. Three years later he was appointed professor of classical literature in the university of Landshut, where he remained until 1826, when that institution was transferred to Munich. In this latter city he spent the rest of his life. In recognition of his services as a teacher and author he was made an aulic councillor, and a member of the Bavarian Academy of Sciences. He died on the 30th of December 1841. Ast was an independent although not an original thinker. He was more of a scholar and critic than a philosopher. He belonged to the school of Schelling, but was ready to welcome truths from the most diverse quarters. His writings on æsthetics,—*System der Kunstlehre* (1805) and *Grundriss der Æsthetik* (1807),—although containing no distinctively new thoughts, had the merit not only of combining and elaborating the principles of Schelling on beauty and art, but of supplementing them to some extent by the views of Winckelmann, Lessing, Kant, Herder, Schiller, Jean Paul, and others, on these subjects. His *Grundlinien der Philosophie*, published in 1807, was republished in 1809, but soon after sank into oblivion. His *Grundriss einer Geschichte der Philosophie*, also published in 1807, was longer lived, and deservedly. It was the best book of the kind which the Schelling school could show, at least until the publication of Rixner's *Manual*, fifteen years later. It is among the earliest of the works pervaded by the thought, so familiar now but so fresh then, that the history of philosophy is not a history of opinions, but the history of reason, the several philosophies being only stages in the development of the one true philosophy, the gradually self-revealing absolute reason. It is also among the earliest attempts to "construe" the history of philosophy and to formulate its law of movement. The author published a second edition of it in 1825, and *Hauptmomente der Geschichte der Philosophie* in 1829. In two works, both published in 1808, he sought to determine and expound the principles of the chief divisions of the study in which he was strongest. They are his *Grundlinien der Philologie* and *Grundlinien der Grammatik, Hermeneutik, und Kritik*. Both have been commended by competent judges. His reputation as a philologist, however, rests mainly on the vast and toilsome labours on Plato, which occupied the last twenty-five years of his life. His *Platon's Leben und Schriften*, published in 1816, is the earliest of those elaborate critical inquiries regarding the life of Plato, the authenticity of the works which have come down to us under his name, the order of their composition, their purpose, plan, &c., which may be regarded as having had their proximate cause in the celebrated *Introductions* of Schleiermacher, and their primary cause in the historical scepticism of Niebuhr and Wolf. He allows scarcely any weight to the ancient biographies and traditions; but, taking a few of the finest dialogues as standards, he draws from them the criteria in virtue of which he accepts or rejects the others. He pronounces spurious not only those compositions which are generally admitted to be so,—the *Epinomis*, *Minos, Theages, Erastæ, Clitopho, Hipparchus, Eryxias*, the *Letters and Definitions*, but also the *Meno, Euthydemus, Charmides, Lysis, Laches*, the *First and Second Alcibiades, Hippias Major and Minor*, the *Ion, Euthyphron, Apology, Crito*, and even, in defiance of the explicit testimony of Aristotle, the *Laws*. He arranges the dialogues, which he admits to be genuine, into three series; the group which he regards as the earliest in date of composition, and which he describes as characterised by the predominance of the poetical and dramatical element, consists of the *Protagoras, Phædrus, Gorgias*, and *Phædo*, the second, distinguished by the marked prominence of dialectic keenness and subtility, comprises the *Theætetus, Sophist, Statesman, Parmenides*, and *Cratylus*; while the third, displaying the dialectical and poetical qualities of Plato's mind in interpenetration and harmony, includes the *Philebus, Banquet, Republic, Timæus*, and *Critias*. This book was followed by a complete edition of Plato's works (1819–32) in 11 vols., with a Latin translation, and a learned commentary, which occupies the last two volumes. Professor Ast crowned these labours by his *Lexicon Platonicum* (1834–9), in 3 vols., one of the most comprehensive and valuable of special dictionaries. He wrote various other works of less importance than those which have been mentioned. (R. F.)

ASTARTE [Ashtaroth] was the chief goddess of the Phœnicians in Zidon, where was a temple in her honour. In Tyre also she had a temple, and from thence her worship was transplanted to Carthage. At what time it may have been introduced among the Jews is not known, but its power of attracting them may be seen by reference to 2 Kings xxiii. 13; 1 Kings xi. 5; Judges ii. 13. Among classical writers the usual epithet of Astarte was *Cœlestis* or *Urania*, but while that distinguishes her only as a goddess of the heavens, it would seem that her name itself signifies "star." Her symbol in her temple at Tyre was a star. Lucian (*De Dea Syria*, 4) expressly identifies her with Selene, the goddess of the moon; others, again, with the planet Venus. With the goddess Venus (*Aphrodite*), as worshipped at Paphos in Cyprus, Astarte had in common the character of a deity of the sky (*Urania*), and perhaps, also the patronage of immorality ("Ashtaroth, the abomination of the Zidonians," 2 Kings xxiii. 13). The Romans, in calling her Juno Cœlestis, appear to have been guided by her connection with Baal, and her position as queen of heaven. At the time of the 19th Egyptian dynasty Ashtaroth was introduced, with other Asiatic deities, into the religious system of the Egyptians, and had a temple at Memphis. But no representation of her occurs on the Egyptian monuments. The Assyrian goddess Ishtar seems to have been the same as Astarte (Movers, *Die Phönizier*, p. 601).

ASTELL, Mary, an English authoress, born at Newcastle-upon-Tyne in 1668. She was instructed by her uncle, a clergyman, in Latin and French, logic, mathematics, and natural philosophy. In her twentieth year she went to London, where she continued her studies. Her efforts were especially directed to the mental improvement of her sex, and she published, in 1697, a work entitled *A Serious Proposal to the Ladies, wherein a Method is offered for the Improvement of their Minds*. With the same end in view she elaborated a scheme for a ladies' college, which was favourably entertained by Queen Anne, and would have been carried out had not Bishop Burnet interfered. The most important of her other works was *The Christian Religion, as professed by a Daughter of the Church of England*, published in 1705. She died in 1731.

ASTER, a genus of composite plants (*Compositæ*), found largely in North America, and scattered sparingly over Asia, Europe, and South America. They are usually perennial, and their flowers are arranged in numerous heads (*capitula*). Asters receive the name of Michaelmas and Christmas daisies, because they have heads like daisies, and, when the weather is mild, they flower up to these periods of the year. They are, consequently, valuable plants in a garden. The only British species is *Aster Tripolium*, found abundantly in saline marshes near the sea. One of the species (*Aster alpinus*) grows at a considerable height on the mountains of Europe. Some of them, such as *Aster spectabilis* of North America, are very showy. The plant called the Cape Aster is *Agathœa amelloides*, while the China aster is *Callistephus chinensis*. Both these plants belong also to the Natural Order *Compositæ*. A variety of the Chinese aster, having beautifully coloured florets of rose, violet, and white, is called Reine Marguerite by gardeners.

ASTERIUS, of Cappadocia, was a heathen sophist and teacher of rhetoric in Galatia. About the year 300 he was converted to Christianity, and became the disciple of Lucian, the founder of the school of Antioch. During the persecution in 304 he relapsed into Paganism, but was received again into the church by Lucian. He is best known as an able defender of the Arian doctrine, and was styled by Athanasius the "advocate" of the Arians. His chief work was the *Syntagma*, but he wrote many others, chiefly commentaries. *Cf.* Mountfaucon, *Collectio Nova PP. et Script. Græc.*

ASTERIUS, Bishop of Amasia, in Pontus, in the end of the 4th and in the beginning of the 5th century. His fame rests chiefly on his *Homilies*, which were greatly esteemed in the Eastern Church. Most of these have been lost, but five were published in a 4to vol. by Ph. Rubenius of Antwerp in 1615, under the title *Asterii Amas. Homil. Quinque, Gr. et Lat.* Combefis published six more, so that we have eleven complete; and Dupin gives fragments of at least twenty-two.

ASTEROIDS, the name given to a large number of small planets, which revolve round the sun in orbits lying between those of Mars and Jupiter. They are all extremely small, their brightness seldom exceeding that of stars of the eighth magnitude; their paths, which cross and recross each other, extend over a belt about 250,000,000 miles in breadth; and the eccentricities of the orbits of many of them, and the inclinations of their planes to the plane of the ecliptic, are much greater than those of the larger planets. All the asteroids have been discovered during the present century. The first seen, Ceres, was discovered by Piazzi at Palermo on the first day of the century (Jan. 1, 1801), Pallas was seen in 1802, Juno in 1804, and Vesta in 1807. The next, Astræa, was not discovered till 1845; three more were seen in 1847, and since that time the number has been increased every year, amounting at the end of 1874 to 140. (See ASTRONOMY, p. 806.)

ASTHMA (ἆσθμα, a gasping, ἀσθμαίνω, to gasp for breath), a disorder of respiration characterised by severe paroxysms of difficult breathing, usually followed by a period of complete relief, with recurrence of the attacks at more or less frequent intervals. The term is often incorrectly employed in reference to states of embarrassed respiration, which are plainly due to permanent organic disease within the chest, and which have none of the distinctive characters of true asthma. The onset of an attack of asthma is usually sudden, although there may exist certain premonitory symptoms which warn the sufferer of its approach, such as a feeling of discomfort, drowsiness, irritability, and depression of spirits. The period when the asthmatic paroxysm comes on is generally during the night, or rather in the early hours of morning. The patient then awakes in a state of great anxiety and alarm, with a sense of weight and tightness across the chest, which he feels himself unable to expand with freedom. Respiration is performed with great difficulty, and is accompanied with wheezing noises. His distress rapidly increases, and he can no longer retain the recumbent position, but gets up, and sits or stands with his shoulders raised, his head thrown back, and his whole body heaving with his desperate efforts to breathe. His countenance is pale or livid, and wet with perspiration, while his extremities are cold; his pulse is rapid and weak, and frequently irregular or intermitting. All his clothing must be loose about him; he cannot bear to be touched, and the very presence of others around him seems to aggravate his distress. His one desire is to breathe fresh air; and he will place himself by an open window and sit for hours in the middle of the night, unmindful of the exposure. His appearance is alarming in the extreme, and it often seems as if each breath would be his last. The paroxysm, after continuing for a variable length of time, often extending over many hours, begins to abate, the breathing becomes easier, and the subsidence of the attack is frequently marked by the occurrence of coughing with expectoration. When the expectoration is abundant the asthma is called *humid*, but where there is a little or none it is termed *dry*. After the cessation of the attack the patient appears to be and feels comparatively well. In cases, however, of long standing the subject of asthma comes to bear permanent evidence of its effects. He is easily put out of breath on exertion and he requires to lie with his head elevated, circumstances to be ascribed to organic changes in the chest, which oft-recurring attacks of asthma are liable to induce. The asthmatic paroxysms, although occasionally periodic, do not generally observe any regularity in their return. They may recur each successive night for several days, or there may be no return for many weeks or months, this being to a large extent dependent on a renewal of the exciting cause. Asthma is much more common in men than in women. In may be developed at any age, but is most frequently observed in early and middle life. A large number of cases take their origin in diseases affecting the respiratory system during infancy, such as hooping-cough, measles, and bronchitis. Asthma is often hereditary, and in all cases one attack appears to predispose to others.

With respect to the pathology of asthma, it is now generally held that the essential nature of the disease consists in a spasmodic contraction of the bronchial tubes. This is due to some deranged condition of the nervous system, affecting, either directly or by reflex action, the nerves supplying the contractile fibres lining the bronchi and regulating their calibre. The bronchial tubes being thus spasmodically narrowed, and losing for the time their expansile power, air can only, with the utmost difficulty, be got into or out of the chest. In these circumstances the muscles of the trunk concerned in respiration are called on to act with great violence to expand the chest, but with little avail, and hence the distress and threatened suffocation. But while asthma is thus to be regarded as essentially a nervous ailment, its occurrence, apart from some organic disease in the chest or elsewhere, is admitted to be comparatively rare. Some cases, however, appear to be of purely nervous origin. To these the term *Nervous* or *Spasmodic Asthma* is applied, and it is more particularly to this form that the symptoms above narrated refer. In such cases no actual disease can be discovered with which the asthma could be directly connected. Attacks of this nature appear capable of being excited in those subject to them in very various ways. Thus violent emotions are not unfrequently the cause of asthmatic paroxysms. The effect of the inhalation of certain effluvia in exciting attacks of asthma is undoubted, as in the familiar instances of the odour of hay and of ipecacuan. In no particular is the eccentric character of this disease more remarkable than in that of locality. Changes of air, otherwise inappreciable, may give occasion to the most severe attacks of asthma, as, on the other hand, they may be the means of accomplishing a cure of the disease where it exists. Circumstances, apparently the most trifling, have been known to give rise to severe paroxysms of asthma, as the extinguishing of a light in a sleeping apartment or the shutting of a door. But asthma is very frequently associated with some form of chest complaint, more particularly bronchitis, and hence the term *Bronchitic Asthma.* The relation between the two ailments in such cases is rendered sufficiently obvious by the fact that the one does not occur without the other; and it is evident that the irritation of the bronchial mucous membrane gives rise by reflex nervous action to narrowing of the tubes. When the bronchitis is cured the asthma disappears. Asthmatic-like paroxysms are also of occasional occurrence in some forms of heart disease, and the term *Cardiac Asthma* is used to describe such cases. They can, however, scarcely be regarded as cases of asthma, but rather as attacks of difficult breathing referable to some impediment to the pulmonary circulation, the result of the heart disease.

The treatment of asthma consists in the employment of remedies to allay the paroxysms, and in the adoption of measures likely to prevent their recurrence. During the attack the patient should be placed in as favourable circumstances for breathing as practicable. He usually selects the position easiest for himself. Abundance of air should be admitted to the apartment, and he should be interfered with as little as possible. The remedial agents employed with the view of relieving the paroxysms are very numerous, and only a few of the more important of them can be alluded to. Opiates administered internally or hypodermically are of known efficacy, as is also the inhalation of anæsthetic vapours. Much value is attached by many to the smoking of stramonium, and even tobacco smoking appears in some instances to give relief. The fumes of nitre-paper (blotting-paper prepared by being dipped in a saturated solution of nitre and dried) burnt in the apartment often succeed in mitigating the paroxysm. The use of the tincture of *Lobelia inflata* is recommended by many high authorities, as are also the employment of emetics, the latter more especially where the attack can be traced to errors in diet. None of these remedies, however, ought to be tried without medical advice. Coffee is a popular and useful remedy, but to do good the infusion must be very strong, and taken upon an empty stomach. To prevent the recurrence of the paroxysms special care must be taken by the sufferer to avoid those influences, whether connected with locality or mode of life, which his experience may have proved to have been the occasion of former attacks. Where the paroxysms are of periodic occurrence the use of quinine or arsenic has been tried with good results. (J. O. A.)

ASTI, a large and well-built town of Italy, in the province of Alessandria (Piedmont), situated on the left bank of the Tanaro. It is the see of a bishop, the chief town of a *circondario,* and a station on the Turin and Alessandria railway. Its Gothic cathedral dates from 1348, besides which there are a large number of churches, a college, an old castle, and a theatre. In the Middle Ages Asti was a great commercial city, and one of the most powerful republics of Northern Italy. It was long famous for its hundred towers, of which a number are still standing. As a free city it opposed Frederick I., but it was taken by him and burnt in 1155. In 1348 it fell into the possession of the Visconti, and thus passed first to France, and then, after the peace of Cambray in 1529, to Charles V., who bestowed it on his aunt, Beatrice of Savoy. In the war of the Spanish Succession it frequently changed hands, and in 1745 was taken by storm by the French. It was the birth-place of Alfieri, whose statue, by Vini, adorns the *piazza.* The inhabitants carry on a considerable trade in corn, wine, and silk, and are also engaged in the manufacture of woollen goods, leather, paper, and hats. Population, about 31,000.

ASTOR, John Jacob, an enterprising American merchant, founder of the Astor Library at New York, was born at the village of Walldorf near Heidelberg, on the 17th July 1763. His father was a peasant, and his early years were spent in the common labours of the farm. At sixteen he joined an elder brother, a musical instrument maker, in London, and at twenty sailed for the United States. On the voyage he became acquainted with a fur-trader, by whose advice he devoted himself to the same business. By his energy, industry, and sound judgment he gradually enlarged his schemes, did business in all the fur markets of the world, and amassed an enormous fortune,—the largest up to that time made by any American. He devoted many years to carrying out a project for organising the fur trade from the Lakes to the Pacific Ocean, and thence by way of the Sandwich Islands to China and India. In 1811 he founded at the mouth of the Columbia River a settlement, named after him Astoria, which was intended to serve as the central depôt; but in the following year the settlement was taken and occupied by the English. The incidents of this undertaking are the theme of Washington Irving's *Astoria.* A series of disasters frustrated the gigantic scheme. Astor made vast additions to his wealth by investments in land in New York city. He made many charitable bequests by his will, and among them a gift of $50,000 to the poor of his native village in Germany. But the deed by which he will be chiefly remembered was the foundation and endowment by his will of the Astor Library at New York, for which he bequeathed the sum of $400,000. The building, erected in Lafayette Place (1850–53), is in the Byzantine style of architecture. Washington Irving was appointed first president, and the formation and arrangement of the library was entrusted to Mr J. G. Cogswell. The building has since been enlarged at the cost of the eldest son of the founder. Mr Astor spent the last twenty five years of his life in retirement, and died at New York, March 29, 1848.

ASTORGA (the ancient *Asturica Augusta*), a city of Spain, in the province of Leon, in a plain near the Tuento. It confers the title of marquis on the Osorio family, the ruins of whose palace, destroyed in 1810 by the French, are still an object of interest. It is surrounded with ancient Roman fortifications, which now afford a pleasant promenade; and there is in the vicinity a ruined castle. It was formerly called the "city of priests," from the great numbers of that profession resident within its walls; and it is still the see of a bishop under the church of Compostella, and has a Gothic cathedral of the 15th century.

ASTORGA, Emmanuele d', a distinguished musical composer, was born at Palermo about 1680. His father, a baron of Sicily, took an active part in the attempt to throw off the Spanish yoke, but was betrayed by his own soldiers and publicly executed. His wife and son were compelled to be spectators of his fate; and such was the effect upon them, that Emmanuele fell into a state of gloomy despondency, which threatened to deprive him of reason, while his mother died on the spot. By the kindness of the Princess Ursini, the unfortunate young man was placed in a convent at Astorga, in Leon, from which town he afterwards took his name. Here he recovered his health, and his admirable musical talents were cultivated under the best masters. In 1703 he entered the service of the duke of Parma, and while at his court produced many compositions. The duke, suspecting that an attachment existed between his daughter and Astorga, dismissed the musician, but gave him a letter of recommendation to Leopold of Austria. The emperor received him kindly, and at his court Astorga produced his pastoral opera of *Daphne.* In 1705, on the death of his patron, he visited Florence, and then London, where he remained for two years, and wrote his *Stabat Mater,* considered the best of all his works. He seems to have resided for some years in Spain, and to have died in Bohemia, at r near Prague. The date of his death is quite uncertain.

ASTRABAD, or ASTERABAD, a small province of Persia, bounded on the N. by the Caspian Sea and the desert, on the S. by the Elburz Mountains, W. by Mazanderan, and E. by the river Gourgan. The country, although mountainous, and interspersed with dense forests, in which it is scarcely possible to travel, possesses beautiful and fertile valleys, producing rice, wheat, and other grains in abundance, or spread out in a boundless expanse of verdure, the pasturage of numerous flocks and herds. Fraser, who travelled through Persia in 1822, extols in the most lavish terms the appearance of the country. The soil, with little culture, is exceedingly productive, owing to the abundance of water which irrigates and fertilises it. But while the province in many parts presents a landscape of luxuriant beauty, it is a prey to the ravages of disease, and the frequent incursions of the surrounding tribes. The heavy torrents which fall in the rainy season stagnate in the forests, forming morasses, which, in the heats of summer and autumn, exhale a pestilential vapour, from the decomposition of the vegetable matter they contain. From these seats of noxious effluvia the wandering tribes of shepherds fly beyond the Gourgan or the Atrek, and live on the verge of the burning sand, although they have to carry water for each day's consumption from the distant river. The better classes retire from the intense heats of summer into the mountains; but the settled inhabitants of the villages, who cannot so easily remove, and who generally remain, suffer severely from sickness. The inhabitants, notwithstanding the unhealthiness of their climate, are a stout and athletic race. The province is famous for furnishing a supply of matchlocks for the king's body-guard. It is the ancient Hyrcania, and the native country of the Kajers, a Turkish tribe, of whom the king is the head, and on whom he considers he can rely in times of danger.

ASTRABAD, or ASTERABAD, the capital of the above province, is situated near the mouth of the River Gourgan, which flows into the Caspian, and at the head of a sheltered bay, convenient for shipping. It is a straggling town, about 3½ miles in circuit, and picturesque in appearance, from the buildings being intermingled with trees and gardens. At one time of greater size, it was reduced by Nadir Shah within its present limits. It is surrounded by a dilapidated mud wall, once lofty and formidable, and defended by numerous towers, and also by a wide and deep ditch, now almost filled with rubbish. Astrabad owes its origin to Yezzen-ibn-Messlub, who commanded the armies of Soliman, the seventh caliph of the Ommiades, early in the 7th century. It was destroyed by Tamerlane in 1384. In 1744 Hanway the English traveller visited the place, and attempted to open a direct trade with Europe. At present its bazaars, though extensive, are but poorly filled, but commercial activity is said to be on the increase, in spite of the insecurity caused by the Turcomans, who attack the caravans at the very gate of the town. The number of houses within the walls is estimated at from 2000 to 3000. Owing to the noxious exhalations of the surrounding forests, the town is so extremely unhealthy during the hot weather as to have acquired the title of the City of the Plague. Distance N.E. of Ispahan, 400 miles. Long. 54° 25′ E., lat. 36° 50′ N.

ASTRAKHAN, a government of European Russia, bounded on the S.E. by the Caspian Sea, N.E. by Orenburg, N. by Saratov, W. by the country of the Don Cossacks, and S.W. by the government of the Caucasus. It lies between lat. 44° 50′ and 49° 50′ N. and between long. 43° 30′ and 51° 0′ E. It has an area of about 84,948 square miles, divided into two nearly equal parts by the Volga, and consists chiefly of sandy deserts, interspersed with saline lakes; but in the delta, and on the banks of the rivers, grapes and other fruits of southern climates are raised. The population in 1867 was estimated at 573,954, comprising Russians, Tatars, Georgians, Armenians, Persians, Hindus, &c., who engage in the rearing of horses, cattle and sheep, and also in fishing for sturgeon, which forms the principal source of the wealth of the government. The vicissitudes of climate are great; with a mean annual temperature of 48° Fahr., the summer averages 70°, and the winter 13° Fahr. The government is divided into four districts:—Astrakhan, Krasnoi-Yar, Zenotaïesk, and Chemyi-Yar. Its capital, Astrakhan, is the only place of much importance.

ASTRAKHAN, the capital of the above government, is situated on a small island in the Volga, about 30 miles above the influx of that river into the Caspian. It is a large, rambling, wood-built city, "dusty in summer, windy in autumn, frozen-up in winter, and knee-deep in mud in spring." It consists of three parts,—(1.) The *Kremlin*, or citadel, dating from 1550, which stands on a hill, and contains the cathedral of the Assumption (1582), a spacious brick edifice of peculiar architecture, with the archbishop's palace, and the convent of the Trinity. (2.) The *Belogorod*, or white town, containing the government buildings, bazaars, &c. (3.) The *Llobodeo*, or suburbs, where the bulk of the population reside. Astrakhan is the seat of a Greek and of an Armenian archbishop; and, besides a number of Greek and Armenian churches and convents, it contains a Catholic and a Lutheran church, a Hindu temple, and several mosques. Mention may also be made of a botanic garden, bazaars, a theatre, a gymnasium, an ecclesiastical seminary, and several inferior schools. From its favourable position the town enjoys a very considerable trade both with the interior of Russia, and with India, Persia, &c. Besides its importance as a fishing station, it has considerable manufactures of cotton, silk, leather, &c. Living is very cheap,—£20 per annum being a fair income for the maintenance of an ordinary family. This city was anciently the capital of a kingdom belonging to the Tatars, who were expelled about 1554 by the Russian prince, Ivan Vassilivich. In 1569 it was besieged by the Turks under Selim, but they were defeated with great slaughter by the Russians. In 1670 it was seized by the rebel Stenko Razin; but in 1671 he was dispossessed of it by his uncle, Jacolof, who remained faithful to the Czar. In 1722, when Peter the Great extended his conquests on the Caspian, Astrakhan was his headquarters. In 1702, 1718, and 1767, it suffered severely from conflagrations, it was plundered by the Persians in 1719, and, in 1830, the cholera swept away a great portion of its inhabitants. Lat. 46° 21′ N., long. 47° 55′ E. Population estimated at 50,000 or 60,000.

ASTROLOGY, the so-called science by which various nations, in various ways, have attempted to assign to the material heavens a moral influence over the earth and its inhabitants. For long ages astronomy and astrology were identified. Isidore of Seville is the first to distinguish between the two; nor did astronomy wholly rid itself of astrology, till, with the system of Copernicus, the conviction that the earth itself is one of the heavenly bodies was finally established. Even at the present day a few may be found who, from a superstitious reverence for the past, or the spirit of contradiction, pride themselves on their adherence to the belief in stellar influences. It is no longer necessary to protest against an error which is dead and buried, but let us pause a moment and ask what we mean by an error With Spinoza we would say that erroneous ideas consist in the fancies and opinions which the senses suggest to the mind in a confused, imperfect, and ill-ordered manner. To this sort of knowledge Spinoza gives the name of vague experience. This vague experience is further complicated by the employment of signs, which flatter the fancy, and of which we form ideas like those which the objects themselves presented at first to our imagination. If to these two elements—vague experience and the misleading use of signs—we add the instinctive impulse which led primitive man to imagine a universe created according to the analogy of his mind, we have before us the three causes which led the Indians, Greeks, Egyptians, Chaldeans, and their Alexandrian disciples, the Arabs and their followers, during the Middle Ages and the Renaissance, to lend themselves to the illusions of astrology, and by a preposterous philosophy to deduce the laws of nature from a theory of morals.

Astrology is generally divided into natural astrology, the science which predicts the motions of heavenly bodies and eclipses of sun and moon, and judicial astrology, which studies the influence of constellations on the destiny of men and empires. But it is obvious that both of these branches presuppose an advanced stage of astronomical knowledge, and a state of society not necessarily better but more complex than that in which the first worshippers of the heavens were placed. It follows, then, that both natural astrology and judicial astrology must have been preceded by a science less learned in heavenly motions and at the same time (as we shall attempt to show) more moral in the best sense of the word. Astronomers have taken very little pains to trace their favourite science to its source by help of the copious astrological commentaries in which the earliest observers embodied their theories of the heavens. Philosophers, with the single exception of Schopenhauer, have shown the same indifference. Of modern writers who have treated of astrology, some, like M. Alfred Maury, have sought to place its errors in a ridiculous light; others, like Eusèbe Salverte, have exposed the quackeries which rendered it a possible profession; and lastly, a few, like Eliphas Lévi and M. P. Christian, simply attempt to build up again with words a belief which has ceased to rest either on facts or ideas. Neither class of writers is likely to advance the history of human reason. The time has come for a calm and dispassionate survey of an illusion which for a while seemed probable, and may even be said to have done good service in its day. How did the error arise? Whence its persistency? These are questions which demand an answer, if only in order to preserve modern science from illusions which, though differing in form, are in their essence similar.

M. Alfred Maury begins his treatise by examining what are the beliefs of savages on the subject of magic and astrology. So too M. F. Höfer, in his *History of Astronomy*, well remarks: "If we wish to seek for the origin of the science, let us place a child or a savage in presence of the earth and the heavens, and ask what thoughts these suggest to him. We shall then obtain a clue to guide us on our path." We shall do well to follow the example of MM. Maury and Höfer, provided we do not confuse the savage of a superior and the savage of an inferior race, or the ancient savage and the modern child. But how can we question the ancient savage? Only by help of his cosmogonies.

It was long before man learned to distinguish the planets from the fixed stars; even then, as the word πλάνητες proves, he assigned to them an erratic instead of a regular motion. Further, we must bear in mind that the first star-gazers had no knowledge of optics, physics, or meteorology, to teach them that the blue of the firmament is a subjective phenomenon caused by the light traversing our atmosphere before it strikes the optic nerve; that its regular spherical form is an effect of perspective; that winds, clouds, and northern lights are terrestrial phenomena related to astronomy, but distinct from the science of the true heavens. The ancestors of the sublime and childlike bards of the Rig-Veda deified the morning glow *Arustra*, and the diurnal and nocturnal heavens as the twin brethren who had been nursed on the bosom of *Aditi*. Aditi with them is the space beyond the horizon. Aditi is the sky, heaven. Aditi is mother, father, son. The gods were *Adityas, i.e.*, children of Aditi. Aditi, in a word, was boundless space, but space endowed with life, form, and power,—the power, namely, of delivering men from the heaviest of their chains, that is, sin. Aditi, too, is the mother of storms (*Rudras*). With the original Aryans storms represented the fecundating principle. Thus they pictured the storm among the clouds under the lively image of a bull among cows. Hence the celestial animals. The horse had been already placed in heaven to represent the sun (*Asva*). The fire of the hearth, too, which they produced by rubbing two sticks together, was as much a god as *Varuna* and *Mitra*, and worshipped as *Agni*, one of the Adityas. Such was the innocent childhood of the Hindus, which originated a poetical mythology so closely allied to science, so rich in moral lessons,—could such innocence last?

Let us pass on to astrology as we find it among the Etruscans. We shall see the moral astrology of the primitive Aryans changed into political astrology. The word *templum*, the diminutive of *tempus*, as Varro tells us (*de Ling. Lat.* lib. vi.), signified—1, a division of the sky; 2, a spot on earth marked out by auspices; 3, by analogy, a spot below the earth. The augur with a staff (*lituus*) traced a line from north to south called *cardo*, and another from east to west called *decumanus*. Thus a *temple* consisted in marking out a spot; the entry was from the south, the sanctuary was at the north, propitious signs came from the east, unpropitious from the west. The same precautions which, according to Columella, agriculturists took in transplanting a tree to preserve the same aspect for roots and branches, the Romans, as disciples of the Etruscans, observed in fixing the site of their camps, their towns, &c., and not only this, but their observation of the flight of birds, their curious commentaries on the various forms of thunder and lightning, may all be reckoned as parts of astrology, inasmuch as to the Etruscan bards air and thunder appeared celestial phenomena. Just as Chinese astrologists professed the power of producing or averting eclipses, the Etruscan priests asserted that they could draw down or divert lightning. In fact, such claims are a common characteristic of what we have ventured to call political astrologies: everywhere political astrologists have laid claim to the production of phenomena which calculation, empiricism, or good fortune has enabled them to predict. If perchance their prediction failed, they saved their credit by saying that by their art they had averted the impending disaster. The Etruscans called their deities *consentes*, sharers of the destinies of their race, and believed that they were fated to perish after a reign of 6000 years. This doctrine of the renovation of heaven, earth, and gods, is found to prevail wherever politics, the growth of conquest, have supplanted the simple and childlike faith which springs up of itself among an innocent and unconquered race. When a nation left its home,—that land and sky which both witnessed the birth of its religion, and was part and parcel of that religion,—its priests gradually lost faith in their religion, and began to mix up politics with religion; its astrologers, whose business it was to interpret the signs of the heavens, felt that their power was doomed, and predicted a universal ruin, in which the nation, its religion, its gods, and heaven itself, were involved. But hope, which springs eternal in the human breast, made them add to their prophecy, that after the exhaustion of evil and the death of perverted races, a new order of things should be born. This is the creed of Hesiod's sublime cosmogony;

this is the burden of the 4th ec.ogue, in which Virgil has clothed the solemn strains of Etruria with a tenderness that is all his own. India, Egypt, Arabia, have all held the same belief, though the period between each palingenesis is different with each. Later on we shall meet with the same doctrine in the subtle doctor Cardan, though strangely disguised. With the Romans, before they were initiated into the learning of Greece, astrology was only another name for sorcery. Most readers will remember the picture in Tibullus of the witch who can draw down the moon by her charms, or succour the labouring moon. They can understand the idea of Heraclitus (for Greece, too, passed through this stage of meteorological psychology), who thought that truth is mixed up with the atmosphere, and that the sage breathes it. The same idea is thus rendered by Ovid, *Fasti* i. 473,—

> "Quæ, simul æthereos animo conceperat ignes,
> Ore dabat vero carmina plena dei."

This is the genuine *ἐνθουσιασμός*. Nearly every one is familiar with the famous passage in the fourth *Georgic*, beginning "*Esse apibus partem divinæ mentis et haustus*," and the noble commentary of the poet which follows.

It was the sober belief of primitive Greece that the sun was a torch, and the stars candles periodically lit and extinguished. Xenophanes was the first philosopher who developed this astrological idea, and expounded the connection of the stars with the earth. Xenophanes thought that the stars were meteors, that is, terrestrial effluvia. This enables us to explain the malignant influence on plants and animals which both Greeks and Romans attributed to the stars, and expressed respectively by the words *ἀστροβολεῖσθαι* and *siderari*. The latest development of this belief is to be found in an English philosopher, who has written a book which proves that epidemics are due to the shocks of comets (Forster, *Illustrations of the Astronomical Origin of Epidemic Diseases*, Chelmsford, 1829). An American, in a work which shows some lucid intervals, borrows directly the thesis of Xenophanes, and demonstrates that wicked men contaminate the heavens and stars by their breath. Modern hallucinations are often the best commentary on ancient errors.

But the true source of astrology must be sought for in a remoter age than any we have yet reached. So far we have seen men grouped together as nations, possessing laws, reckoning more or less perfectly the course of time, making capital out of the defects of their calendar, like the Romans, or, it may be, complaining of those defects, and hailing the advent of a Meton like the Athenians in Aristophanes's *Clouds*. But there must have been long preceding ages during which the passage of time was unmarked and unrecorded. Does not this idea of time mark the first stage of civilisation? Some savages cannot reckon at all; others, like children, cannot go farther back than yesterday, or the day before yesterday; others, again, can only mark the year by the changes of the seasons, and their only landmarks for the past are great calamities which have befallen the tribe. But it would be a great mistake to conclude that Chaldeans, Persians, Egyptians, &c., set to work methodically to invent a system of notation, and to map out time into years and months. Assuredly, if men had had no other end in view than the possibility of some day or other keeping double entry, figures would be still to seek. Similarly, if men had thought that the chief result of the various researches and discoveries which a calendar presupposes, would be to enable them to make an appointment a month beforehand, the inducement would have proved insufficient. Fortunately, there were other and higher motives to urge on our ancestors of various races in the path of discovery—those of religion and of astrology. The earth, as Hesiod tells us, was once a common abode of gods and men. These are two remarkable lines of Homer (*Od.* xviii. 136), which Aristotle quotes, and Cicero has translated :—

> 'τοῖος γὰρ νόος ἐστὶν ἐπιχθονίων ἀνθρώπων
> οἷον ἐπ' ἦμαρ ἄγῃσι πατὴρ ἀνδρῶν τε θεῶν τε.'

Such was Homer's astrology. But as, in course of time, each superior race in turn degenerated through the effects of conquest, either by mixing with inferior races, or by oppressing their equals (thus, for instance, the Lacedæmonians mixed with the Messenians or Helots, and thus the primitive Aryans oppressed the Dravidian tribes), as each race passed from the age of gold, the age of innocence, to the age of bronze or iron, of Krali or evil, so, to compensate in some way for the loss of morality, we find them making discoveries in science and art. Thus swords were forged of iron, notwithstanding that iron (according to the Finnish legend) had sworn never to slay men. Thus, too, they began to distinguish the several constellations through which the sun appeared to pass. Let us turn to the strange *Theogony* of Hesiod (l. 119 *seq.*), we shall find that Chaos is the parent of Night and Erebus; but the Earth,—seemingly because it had been the peaceful abode of the Immortals who dwell on the snowy peaks of Parnassus, partly, too, because the fairest of the Immortals is Love,—the Earth is the parent of the Heavens :—

> "Tellus vero primum quidem genuit parem sibi
> Cœlum stellis ornatum ut ipsam totam obtegat,
> Utque beatis sedes Divis tuta semper," &c.

That the gods inhabited the mountains or groves before they migrated to heaven is a universal belief. But in what can this heaven of the gods be said to resemble earth? A tradition, which Manilius has preserved, informs us that when Justice was banished from the earth she took up her abode, not in the heart of a king of France (there was then no France or king in the modern sense of the word), but in heaven as one of the constellations of the zodiac.

The zodiac was the heaven which exactly corresponded to the earth (the first astronomers, we need not remark, knew nothing of declinations); it was the zodiac which protected the earth, taught the earth its duties, pointed out not only days and seasons, but the proper work for each day and season. The zodiac was the first book that lay open for all to read, written in runes, as the Scandinavians thought,—in *mim* and *elif* as the Arabs interpreted it,—and in the hieroglyphics of animals and symbols, according to Assyrians and Egyptians. But, alas! this grand conception, which seemed so true to the first astronomers, was obscured by the continual displacement of the zodiac. Thus, in judicial astrology the sign under which a child is born is always the ram, as in our almanacs it is the first sign of the year. Thus, too, the sign of Jupiter ♃ in a slightly altered shape, still heads our prescriptions. Nor is this the only remaining trace of zodiacal belief. For not only was agricultural and political life regulated at first directly by the zodiac, and then through the calendar, but the zodiac applied no less to civil life. Hence the Roman ides and kalends, hence the Greek decade, hence the week of the Jews and other nations. This is not the place to discuss the difficult question of the relation of the zodiac to the week; for our purpose it is enough to observe, that it was by the days of the week, each placed under the protection of some stellar deity, that the priests regulated the whole civil life of a nation, its law courts, its markets, and marriages. The primitive week began with the day of Saturn, the ancient Bel of the Assyrians, so called in distinction from the younger Bel, *i.e.*, Jupiter, and it ended with the day of Venus, the Assyrian Mylitta. This day, which was afterwards held accursed by the Christian Fathers, was probably consecrated to marriages. Saturn's day, or the day of Soetere, was identified with the Sabbath, and Sunday with the Lord's day; the day of Venus with that of Friga, the goddess of love (Friday); Jove's with that of the Norse Thor (Thursday); Mercury's with that of Woden, the god who grants wishes (Wednesday); and Mars's with that of Tiw, the god of war (Tuesday). The Latin division of days into *dies fasti* and *nefasti* has perpetuated the same distinction of lucky and unlucky days which inspired Hesiod's *Works and Days.* Many a tradesman at Rome must have made the same complaint as La Fontaine's cobbler, "*On nous ruine en fêtes.*" With the Arabs Tuesday and Wednesday were the days for blood-letting, Mars being the lord of iron and blood, and Mercury of the humours. Even at the present day, travellers tell us, when an auspicious day has been proclaimed by the astrologers, the streets of Baghdad may be seen running with blood from the barbers' shops. We see how soon the invention of the week became the engine of politicians and astrologers.

Our investigations have now brought us to judicial astrology, which is nothing else than the corruption of the purer astrology, the various phases of which we have attempted to trace. In a book published at Geneva in 1643, the year of Condé's great victory, and of the succession of Louis XIV., entitled *Janua Aurea reserata quatuor linguarum*, 12mo, by J. A. Comenius, we find the following definition:—"*Astronomus siderum meatus seu motus considerat: Astrologus eorumdem efficaciam, influxum, et effectum.*" Kepler was more cautious in his opinion; he spoke of astronomy as the wise mother, and astrology as the foolish daughter, but he added that the existence of the daughter was necessary to the life of the mother. Tycho Brahe and Gassendi both began with astrology, and it was only after pursuing the false science, and finding it wanting, that Gassendi devoted himself to astronomy. In their numerous allusions to the subtle mercury, which the one makes when treating of a means of measuring time by the efflux of the metal, and the other in a treatise on the transit of the planet, we see traces of the school in which they served their first apprenticeship. Huyghens, moreover, in his great posthumous work, *Cosmotheoros, seu de terris cœlestibus*, shows himself a more exact observer of astrological symbols than Kircher himself in his *Iter exstaticum.* In that remarkable discussion on the plurality of worlds, which was at once translated into French, and afterwards reproduced in a popular form by Fontenelle, Huyghens contends that between the inhabitants of different planets there need not be any greater difference than exists between men of different types on the earth. "There are on the earth," continues this rational interpreter of the astrologers and chiromancers, "men of cold temperament who would thrive in Saturn, which is the furthest planet from the sun, and there are other spirits warm and ardent enough to live in Venus." Astrology among the Egyptians, the Chaldeans, and at Alexandria, had established a complete parallelism between men of different types and the planets, on the basis of their relative distance from the sun. These different types of character had been fixed by the Greeks in their conception of the planetary gods, Apollo, Mars, Mercury, Jupiter, and Venus. To these the cabalists added the moon, as the planet corresponding to the pl legmatic temperament of the northern races. Apollo represented the nervous physique which Carus has rightly pronounced the most intellectual. But whence did the notion of this parallelism originate? The solution of this problem will elucidate the practical side of astrology.

Let us once more revert to the first infancy of science. From the general tendency of primitive man to bring all knowledge under a single head, we may safely conclude that the first study of the heavens embraced and dominated over every other attempt at science. The cosmogonists pretended to explain the earth by the heavens, but as they were bound to proceed from the known to the unknown, they did, in fact, explain the heaven by the earth and, in particular, by men. Hence, in many mythologies, the universe is an egg, and in that of Finland a duck's egg, the spots on the shell representing the constellations. Later on we find the eternal revolution and renovation of the universe symbolised by a serpent biting its tail. Lastly, the universe as a perfect and harmonious order, a κόσμος, is conceived as the highest organism to be found on earth, a huge animal. This cosmical animal in turn, owing to the interlacing of religious ideas, images, and symbols, was supposed to influence the different parts of the body. This gives us the clue to the first steps of medical science, which, like the other sciences, began by being astrological. In short, the first encyclopædia was astrology. There is a well-known story of the case of two brothers who fell ill at the same instant. Posidonius the astrologer, on being consulted, pronounced that they were born under the same constellation. Hippocrates the physician concluded from the coincidence that they must be twins; yet even Hippocrates could not rid himself of the terrestrial theory of the heavens. (See chap. 11, *de auris, de aquis, de locis.*) The Egyptians peopled the constellations of the zodiac with genii; the ram (*Arnum*) was lord of the head; the bull (*Apis*), of the neck and shoulders; the twins (Hercules and Apollo), of the arms and hands; and lastly, to the fishes were assigned the feet. The Persians, again, ascribed to the empyrean generally the influence over the citadel of the body—the head. Dionysius the Areopagite, indulging his religious proclivities, established hierarchies of genii in the constellations. The Assyrians were led by their form of government to place thirty-six conciliar-gods in the twelve signs of the zodiac, and to the interpreter-gods, whose province it was to inspect and survey the various divisions of the heavens, they allotted the wandering planets. Whenever a new discovery was made in medicine or science, the province of the god-stars was immediately enlarged; thus the Egyptians, observing the symmetry of the human body, and connecting this with the dualism of human faculties, at once made the sun (*Ra*) the lord of the forehead, the moon mistress of the brain, and Mercury of the tongue; but to Saturn they assigned only the left eye; to Jupiter was given the right; Mars had the right nostril, Venus the left. Meanwhile, in another quarter of the globe a religion was growing up,—a religion of mild anthropomorphism, wholly removed from Oriental transcendentalism. It is in Greece, whose deities had been gradually moulded and drilled so as to serve as types of men and manners, that we must look for the key of astrology. Jupiter, the embodiment of authority, and Cronos, or Saturn, the impersonation of malignant opposition to authority, are the two most prominent figures of ancient mythology. Venus was placed below Mars; that is, the sensual passion was subjected to martial ardour. The astrologers of the Renaissance deviated from the Egyptians in assigning the right nostril to Venus, and the left to Mars: the reason was, that, with Cardan and Vanini, Venus represented rather the German Friga than the Eastern Mylitta,—chaste love rather than luxury. Those of our readers who wish to learn further the opinion of Cardan and Vanini, we would refer to the *Amphitheatrum æternæ Providentiæ* and *De admirandis naturæ reginæ deæque mortalium arcanis libri quatuor*, in which the mocking astrologer breaks a lance with the too subtle philosopher. The quarrel between two learned doctors of the art naturally resulted in the death of the patient. Astrology, already at its last gasp, could not bear such rude treatment. Vanini, the Lucian among astrologers, the hero who exclaimed, as he was being led to the stake, "Courage—let them see how a philosopher can die," has in his works crushed Aristotle by the help of Averroes, and Averroes and Cardan by the help of good sense. And yet the good-humoured satirist, who suffered for his free speech by having his tongue cut out, and being then burnt at the stake, was, notwithstanding, the disciple of Averroes, and the admirer of Cardan. So true is it that reason in its early stages of civilisation is the good genius of the privileged few, who, unlike many moderns, have more sense than they give themselves credit for,—a privilege which they dearly purchased by persecution, or, worse still, by neglect.

Under Albumazar (776–885), astrology, returning to Persian and Græco-Egyptian ideas, appears as the legislator of action and religion. The Caliph Al-Mamun embraced the theory of his favourite astrologer, which fixed the duration of the Mahometan religion at 544, and that of Christianity at 1460 years. Is not this fact in itself sufficient to explode the generally received notion of Mussulman intolerance? Cardan developed this thesis. In one plan he makes Christianity born under Jupiter and Mercury (authority and cunning); and, according to this horoscope, it was destined to be short-lived. For once Vanini is found quoting Cardan with ill-concealed satisfaction. But afterwards, to curry favour with the Papacy, he recants, and says that Christianity was born under the most favourable conjunction of the planets Jupiter and the sun (authority and justice). Thereupon Vanini attacks Cardan under the assumed mask of a Dutch atheist. This example will suffice to show us how astrological symbols were employed by the sceptics, and what interpretation we must put upon their astrological phraseology.

We may now describe the ordinary proceedings of an astrologer. The zodiac was first arranged in much the same fashion as the cards in the game of Tarots. The four ages of man had each three houses in the zodiac. Each of this triple series was composed of a cardinal, a succeeding, and a declining or cadent house. Disastrous signs predominated over auspicious. For kings and nobles these signs were modified, but they took care to preserve a copy of the horoscope to be modified as circumstances required. Pascal remarks,—"They say that eclipses portend misfortunes, because misfortunes are common, so that, as some ill chance often happens, they are often right, whereas if they said that they portended good fortune, they would be generally wrong. They only assign good fortune to rare conjunctions of the stars, and this is how their predictions rarely fail." Those ages during which astrologers were dominant by the terror they inspired, and sometimes by the martyrdom they endured when their predictions were either too true or too false, were in truth the saddest in the world's history. Faith, to borrow their own language, was banished to Virgo, and rarely shed her influence on men. Cardan, for instance, hated Luther, and so changed his birthday in order to give him an unfavourable horoscope. In Cardan's times, as in those of Augustus, it was a common practice for men to conceal the day and hour of their birth, till, like Augustus, they found a complaisant astrologer. But, as a general rule, astrologers did not give themselves the trouble of reading the stars, they contented themselves with telling fortunes by faces. They practised chiromancy, and relied on afterwards drawing a horoscope to suit. As physiognomists their talent was undoubted, and we may again call Vanini as a witness that there is no need to mount to the housetop to cast a nativity. "Yes," he says, "I can read his face; by his hair and his forehead it is easy to guess that the sun at his birth was in the sign of Libra and near Venus. Nay, his complexion shows that Venus touches Libra. By the rules of astrology he could not lie." No doubt, by the rules of chiromancy, a calm forehead, clustering locks, a clear and sanguine complexion, are signs of sincerity. If we combine Apollo and Venus, *i.e.*, manliness and tenderness, the product is sincerity. If we wish to see this type of character to perfection, we have only to look at a good portrait of Spinoza.

In conclusion, we shall give a few salient facts concerning the astrologers and their predictions, remarkable either for their fulfilment, or for the ruin and confusion they brought upon their authors. We may begin with one taken from Bacon's *Essay of Prophecies*:—"When I was in France, I heard from one Dr Pena, that the queen mother, who was given to curious arts, caused the king her husband's nativitie to be calculated, under a false name; and the astrologer gave a judgment, that he should be killed in a duell; at which the queene laughed, thinking her husband to be above challenges and duels; but he was slaine, upon a course at tilt, the splinters of the staffe of Mongomery going in at his bever." A favourite topic of the astrologers of all countries has been the immediate end of the world. As early as 1186 the earth had escaped one threatened cataclysm of the astrologers. This did not prevent Stoffler from predicting a universal deluge for the year 1524—a year, as it turned out, distinguished for drought. His aspect of the heavens told him that in that year three planets would meet in the aqueous sign of Pisces. 'The prediction was believed far and wide, and president Aurial, at Toulouse, built himself a Noah's ark—a curious realisation, in fact, of Chaucer's merry invention in the *Miller's Tale*. In China any false prediction of the astrologers was punished with death. But, as Juvenal remarks in his *Sixth Satire*, the astrologers' chief power depends on their persecution. M. Höfer cannot persuade himself that the Chinese possessed any extensive astronomical knowledge which they afterwards forgot. Still, the position of the astrologists, that is, the astronomers, in China sufficiently explains this relapse in astronomy. They preferred to trust to chance, and live in honour with credulous emperors, at the risk of being hanged by those they failed to please. Inordinate rewards and inordinate punishments made them indifferent to all pure love of science, and life with Orientals has always been reckoned a small stake in the game. Not only was Tycho Brahe from his fifteenth year devoted to astrology, but adjoining his observatory at Uranienburg, the astronomer royal of Denmark had a laboratory built in order to study alchemy, and it was only a few years before his death that he finally abandoned astrology. We may here notice one very remarkable prediction of the master of Kepler. That he had carefully studied the comet of 1577 as an astronomer, we may gather from his adducing the very small parallax of this comet as disproving the assertion of the Aristotelians that a solid sphere enveloped the heavens. But besides this, we find him in his character of astrologer drawing a singular prediction from the appearance of this comet. It announced, he tells us, that in the north, in Finland, there should be born a prince who should lay waste Germany and vanish in 1632. Gustavus Adolphus, it is well known, was born in Finland, overran Germany, and died in 1632. The fulfilment of the details of this prophecy was, of course, nothing but a lucky hit, but we may convince ourselves that Tycho Brahe had some basis of reason for his prediction. He was no dupe of vulgar astrology, but gifted rather with a happy inspiration like that of Paracelsus, who saw in himself the forerunner and prototype of the scientific ascendency of Germany. Born in Denmark of a noble Swedish family, a politician, as were all his contemporaries of distinction, Tycho, though no conjuror, could foresee the advent of some great northern hero. Moreover, he was doubtless well acquainted with a very ancient tradition, that heroes generally came from the northern frontiers of their native land, where they are hardened and tempered by the threefold struggle they wage with soil, climate, and barbarian neighbours.

Kepler explained the double movement of the earth by the rotation of the sun. At one time the sun presented its friendly side, which attracted one planet, sometimes its adverse side, which repelled it. He also peopled the planets with souls and genii. He was led to his three great laws by musical analogies, just as later on an organist of Hanover, William Herschel, passed from music to astronomy. Kepler, who in his youth made almanacs, and once prophesied a hard winter, which came to pass, could not help putting an astrological interpretation on the disappearance of the brilliant star of 1572, which Tycho had observed. Theodore Beza thought that this star, which in December 1573 equalled Jupiter in brilliancy, predicted the second coming of Christ. Astronomers were only then beginning to study variable and periodic stars, and disturbances in that part of the heavens, which had till then, on the authority of Aristotle, been regarded as incorruptible, combined with the troubles of the times, must have given a new stimulus to belief in the signs in heaven. Montaigne (*Essais*, lib. i. chap. 10) relates a singular episode in the history of astrology Charles V. and Francis I., who both bid for the friendship of the infamous Aretin, surnamed the divine, both likewise engaged astrologers to fight their battles. In Italy those who prophesied the ruin of France were sure to be listened to. These prophecies affected the public funds much as telegrams do nowadays. "At Rome," Montaigne tells us, "a large sum of money was lost on the Change by this prognostication of our ruin." The marquis of Saluces, notwithstanding his gratitude to Francis I. for the many favours he had received, including his marquisate, of which the brother was despoiled for his benefit, was led in 1536 to betray his country, being scared by the glorious prophecies of the ultimate success of Charles V. which were then rife. The influence of the Medici made astrologers popular in France. Richelieu, on whose council was Gaffarel, the last of the cabalists, did not despise astrology as an engine of government. At the birth of Louis XIV. a certain Morin de Villefranche was placed behind a curtain to cast the nativity of the future autocrat. A generation back the astrologer would not have been hidden behind a curtain, but have taken precedence of the doctor. La Bruyère dares not pronounce against such beliefs, "for there are perplexing facts affirmed by grave men who were eye-witnesses." In England William Lilly and Robert Fludd were both dressed in a little brief authority. The latter gives us elaborate rules for the detection of a thief, and tells us that he has had personal experience of their efficacy. "If the lord of the sixth house is found in the second house, or in company with the lord of the second house, the thief is one of the family. If Mercury is in the sign of the Scorpion he will be bald, &c." Francis Bacon abuses the astrologers of his day no less than the alchemists, but he does so because he has visions of a reformed astrology and a reformed alchemy. Sir Thomas Browne, too, while he denies the capacity of the astrologers of his day, does not venture to dispute the reality of the science. The idea of the souls of men passing at death to the stars, the blessedness of their particular sphere being assigned them according to their deserts (the metempsychosis of J. Reynaud), may be regarded as a survival of religious astrology, which, even as late as Descartes's day, assigned to the angels the rôle of moving the planets and the stars. Joseph de Maistre, the last and ablest champion of old-fashioned orthodoxy, believed in comets as messengers of divine justice, and in animated planets, and declared that divination by astrology is not an absolutely chimerical science. Lastly, we may mention a few distinguished men who ran counter to their age in denying stellar influences. Aristarchus of Samos, Martianus Capella (the precursor of Copernicus), Cicero, Favorinus, Sextus Empiricus, Juvenal, and in a later age La Fontaine, a contemporary of the neutral La Bruyère, were all pronounced opponents of astrology.

In England Swift may fairly claim the credit of having given the death-blow to astrology by his famous squib, entitled *Prediction for the Year 1708, by Isaac Bickerstaff, Esq.* He begins by professing profound belief in the art, and next points out the vagueness and the absurdities of the philomaths. He then, in the happiest vein of parody, proceeds to show them a more excellent way:—"My first prediction is but a trifle, yet I mention it to show how ignorant these sottish pretenders to astrology are in their own concerns: it refers to Partridge the almanac-maker. I have consulted the star of his nativity by my own rules, and find he will infallibly die upon the 29th of March next about eleven at night of a raging fever. Therefore I advise him to consider of it and settle his affairs in time." Then followed a letter to a person of quality giving a full and particular account of the death of Partridge on the very day and nearly at the hour mentioned. In vain the wretched astrologer protested that he was alive, got a literary friend to write a pamphlet to prove it, and published his almanac for 1709. Swift, in his reply, abused him for his want of manners in giving a gentleman the lie, answered his arguments *seriatim*, and declared that the evidence of the publication of another almanac was wholly irrelevant, "for Gadbury, Poor Robin, Dove, and Way do yearly publish their almanacs, though several of them have been dead since before the Revolution."

Seeing that astrology once permeated all sciences, all religion, and all politics, it is not strange if traces of it crop up when we should least expect them. To astrological politics we owe the theory of heaven-sent rulers, instruments in the hands of Providence, and saviours of society. Napoleon as well as Wallenstein believed in his star. Even now that the science is dead it lives on in our language. Many passages in our older poets are unintelligible without some knowledge of astrology. Chaucer wrote a treatise on the astrolabe; Milton constantly refers to planetary influences; in Shakspeare's *King Lear*, Gloucester and Edmund represent respectively the old and the new faith. We still *contemplate* and *consider*; we still speak of men as *jovial*, *saturnine*, or *mercurial*; we still talk of the *ascendency* of genius, or a *disastrous* defeat.

ETYMOLOGIES.—Belief in the influence of the heavens, the air, and the flight of birds upon human affairs has left traces in all languages. The Greek ἀστροβολεῖσθαι, and the Latin *siderari*, *sideratio*, *templum*, have been already referred to. In French, *heur*, *malheur*, *heureux*, *malheureux*, are all derived from the Latin *augurium*; the expression *né sous une mauvaise étoile*, born under an evil star, corresponds (with the change of *étoile* into *astre*) to the word *malôtru*, in Provençal *malastruc*; and *son étoile pâlit*, his star grows pale, belongs to the same class of illusions. The Latin *ex augurio* appears in the Italian *sciagura*, *sciagurato*, softened into *sciaura*, *sciaurato*, wretchedness, wretched. The influence of a particular planet has also left traces in various languages; but these must rather be explained by chiromancy than by astrology. The French and English *jovial* and the English *saturnine* correspond rather to the gods who served as types in chiromancy than to the planets which bear the same names. But this is not the case with the expressions *bien* or *mal luné*, well or ill-mooned, *avoir un quartier de lune dans la tête*, to have the quarter of the moon in one's head, nor with the German *mondsüchtig* and the English *moonstruck*; the fundamental idea of such expressions lies in the extraordinary opinions formerly held about the moon. The belief in good or evil influence by the mere medium of a look has also left its mark on language; as in the Italian *il buon*, *il cattiv' occhio*, the good, or evil, eye; *la jettatura*, bewitching by a look, &c. (J. A.)

ASTRONOMY

ASTRONOMY (from ἄστρον, a star, and νέμω, to classify or arrange) is the science which deals with the distribution, motions, and characteristics of the heavenly bodies. It is here treated of under two heads: first, the History of Astronomy; and, secondly, Theoretical Astronomy, in which the different theories of the motions of the celestial bodies are explained, and such facts described as observation has made known respecting their nature and constitution.

Part I.—History of Astronomy.

Origin of the science.

Astronomy may probably be regarded as the most ancient of the sciences. Even the least civilised races must have recognised the regular vicissitudes of day and night (and, therefore, the diurnal course of the sun), while before long the variety and succession of the seasons would be noted, and their cause—the oblique annual motion of the same luminary—would be recognised. The moon in the sun's absence is so conspicuous and so useful that her motions, her various phases, and her regular disappearance and return after equal intervals of time, must have been watched in the earliest times with attention and interest. The occurrence of eclipses and other unusual phenomena would stimulate closer scrutiny. The spectacle of the starry heavens, seemingly unchangeable, save for the motions of a few wandering orbs along a certain zone of the star-sphere, early suggested an association between the fates of men and nations and these emblems of unchanging destiny on the one hand and of the changeful lot of mankind on the other. Thus *astrology* had its origin,—a superstition which bore the same relation to astronomy that alchemy bore to chemistry. Like alchemy, astrology was of service—superstition though it was—in encouraging observation and in leading to discoveries of interest.

But though mankind were probably first impelled by motives of mere curiosity to observe the courses of the stars, no great length of time could have elapsed ere they perceived that the regular and uniform revolutions of the heavens might be rendered subservient to their own wants and conveniencies. By the help of the stars the shepherd, during the night, could count the hours, the traveller track his course through the uniform wastes of the desert, and the mariner guide his bark over the ocean: the husbandman, also, learned to regulate his labours by the appearance of certain constellations, which gave him warning of the approaching seasons. The indications derived from the simple observation of such phenomena were doubtless extremely vague; but as civilisation advanced, the necessity of determining accurately the length of the solar year and of the lunar month, in order to regulate the calendar and the religious festivals, led to the accumulation and comparison of different observations, whereby errors were gradually diminished, and the foundations laid of a more perfect science.

Astronomy thus presenting so many objects of curiosity and interest, and having so many practical uses, could not fail to be one of the sciences first cultivated by mankind. Its origin is, consequently, hid amidst the obscurity of remote ages, and is, in fact, coeval with the earliest development of the human intellect. The records or traditions of almost every ancient nation furnish some traces of attention to the state of the heavens, and of some rude attempts to discover the laws, the order, and the period of the most remarkable phenomena, such as eclipses of the sun and moon, the motions of the planets, and the heliacal risings of the principal stars and constellations. The Chaldeans and Egyptians, Chinese and Indians, Gauls and Peruvians, equally regard themselves as the founders of astronomy,—an honour, however, of which Josephus deprives them all, in order to ascribe it to the antediluvian patriarchs. The fables relating to the two columns of brick and marble which these sages are said to have erected, and on which they engraved the elements of their astronomy, to preserve them from the universal destruction by fire and water to which they are said to have learned from Adam the earth was doomed, are not worth the trouble of repetition; nor is there any better proof than the assertion of that credulous historian, of their acquaintance with the *annus magnus*, the astronomical cycle of 600 years, which brings back the sun and moon to the same points of the heavens so nearly, that its discovery implies a pretty correct knowledge of the solar and lunar motions. Passing over those details of traditional observations or unimportant facts, we proceed to give a brief account of the state of astronomy among some early nations who have undoubtedly contributed to the improvement of the science, or who, at least, have transmitted to future ages some records of their astronomical labours.

Astronomy of the Chaldeans, Egyptians, Phœnicians, Chinese, and Indians.

According to the unanimous testimony of the Greek historians, the earliest traces of astronomical science are to be met with among the Chaldeans and Egyptians. The spacious level and unclouded horizon of Chaldea afforded the utmost facilities for observing the celestial phenomena; and its inhabitants, enjoying the leisure afforded by a pastoral life, and stimulated by the vain desire of obtaining a knowledge of the future from the aspects of the stars, assiduously cultivated astronomy and astrology. By a long series of observations of eclipses, extending, according to the testimony of some authors, over nineteen centuries, or even a longer period, they had discovered the cycle of 223 lunations, or eighteen solar years, which, by bringing back the moon to nearly the same position with respect to her nodes, her perigee, and the sun, brings back the eclipses in the same order. This is supposed to be the period which they distinguished by the name of *Saros*. They had others, to which they gave the names of *Sossos* and *Neros*; but nothing positive is known with regard to their nature or extent. It is certain, however, that these Chaldaic periods, whatever they were, were purely empirical. Detected by the comparison of recorded observations, they imply neither theory nor science, unless, indeed, a simple arithmetical operation is to be considered as such; nor is there any reason to suppose that the Chaldeans employed any process of computation whatever in their predictions of eclipses. Having once established their cycle they were in possession of a simple means of predicting all those which occurred in the course of it, with as great a degree of accuracy as they considered requisite. Chaldeans.

The Egyptians were in ancient times the rivals of the Chaldeans in the cultivation of astronomy; and although they have left behind them still fewer monuments of their labours, they have obtained, through the exaggerated statements of the Greeks, even a greater reputation. The Greeks acknowledge themselves indebted to the Egyptians for their science and civilisation; but regarding themselves likewise as descendants of that ancient people, they indulged their vain-glory in magnifying the accounts of the antiquity and knowledge of their supposed ancestors. It is not improbable that some traditional observations of the Egyptians.

heavens, along with some arts indispensable to society even in its earliest stages, were carried into Europe by tribes migrating from the banks of the Nile; and it is certain that the early philosophers of Greece travelled into Egypt for the purpose of acquiring a more perfect knowledge of astronomy than could be obtained in their own country. But the facts from which it can be inferred that the Egyptians had much to communicate, are few and ill-attested. They are also blended with so much absurdity and fable, that no accurate notions can be formed, from the accounts that have been transmitted to us, of the real advances which that people had made in astronomical science. The priests were the depositaries of the national knowledge; and they carefully concealed it from the common people by shrouding it in allegories, traces of which, it has been remarked, may be detected in the institutions even of the present day.

Phœnicians.

The Phœnicians are also generally enumerated among the nations who cultivated astronomy at a very early period, though it does not appear, from any facts mentioned by ancient authors, that they devoted themselves specially to the observation of the heavens, or made any discoveries relative to the motions of the planets. That they excelled in the art of navigation is certain, from the commercial intercourse which they carried on with many places on the coasts of Africa and Spain, and with the principal islands of the Mediterranean; and it may readily be allowed that in their long voyages they would direct their course during the night by the circumpolar stars. If they had any speculative notions of astronomy, these were probably derived from the Chaldeans or Egyptians.

In China, astronomy has been cultivated from the remotest ages, and has always been considered a science indispensably necessary to the civil government of the state. The Chinese boast of a series of eclipses, recorded in the annals of the nation, extending over a period of 3858 years, all of which, they affirm, were not only carefully observed, but were calculated and figured previous to their occurrence. The same motives which led the Chaldeans and Egyptians to attend to the celestial phenomena, namely, the regulation and division of time, had equal influence among the Chinese, and we accordingly find the care of the calendar occupying the attention of their earliest princes. The emperor Fou-Hi, whose reign commenced about 2857 years before our era, is said to have assiduously studied the motions of the celestial bodies, and laboured to instruct his ignorant subjects in the mysteries of astronomy. But as they were not yet enlightened enough to comprehend his theories, he was obliged to content himself with giving them a rule for the computation of time by means of the numbers 10 and 12, the combination of which produces the cycle of 60 years, which is the standard or unit from which they deduce their hours, days, and months. Tradition is silent with respect to the sources from which Fou-Hi derived his own knowledge. In the year 2608 B.C., Hoang-Ti caused an observatory to be built, for the purpose of correcting the calendar, which had already fallen into great confusion, and appointed one set of astronomers to observe the course of the sun, another that of the moon, and a third that of the stars. It was then discovered that the twelve lunar months do not exactly correspond with a solar year; and that, in order to restore the coincidence, it was necessary to intercalate seven lunations in the space of nineteen years. If this fact rested on undoubted evidence, it would follow that the Chinese had anticipated the Greeks by 2000 years in the discovery of the Metonic cycle. The reign of Hoang-Ti is also rendered memorable by the institution of the Mathematical Tribunal, for promoting the science of astronomy, and regularly predicting eclipses, to which an extraordinary importance has always been attached in China. The members of this celebrated tribunal were made responsible with their lives for the accuracy of their predictions, by a law of the empire, which ordained that, "whether the instant of the occurrence of any celestial phenomenon was erroneously assigned, or the phenomenon itself not foreseen and predicted, either negligence should be punished with death." In the reign of Tchong-Kang, the two mathematicians of the empire, Ho and Hi, were the victims of this sanguinary law—an eclipse having taken place which their skill had not enabled them to foresee. The emperor Yao, who mounted the throne, according to the Chinese annals, about the year 2317 B.C., gave a new impulse to the study of astronomy, which had begun already to decline. He ordered his astronomers to observe with the utmost care the motions of the sun and moon, of the planets and the stars, and to determine the exact length of each of the four seasons. To this emperor are attributed the Chinese division of the zodiac into 28 constellations, called the houses of the moon, and the severe laws already noticed in regard to the erroneous prediction of the celestial phenomena. From the time of Yao the Chinese year consisted of $365\frac{1}{4}$ days. They also divided the circle into $365\frac{1}{4}$ degrees, so that the sun daily described in his orbit an arc of one Chinese degree. Their common lunar year consisted of $364\frac{348}{940}$ days; and by combining this number with $365\frac{1}{4}$, they formed the period of 4617 years, after which the sun and moon again occupy the same relative positions.

The earliest Chinese observations we are acquainted with, sufficiently precise to afford any result useful to astronomy, were made by Tcheou-Kong, whose reign commenced about the year 1100 before our era. Two of these observations are meridional altitudes of the sun, observed with great care at the village of Loyang, at the time of the summer and winter solstices. The obliquity of the ecliptic thus determined at that remote epoch is 23° 54′ 3″·15—a result which perfectly agrees with the theory of universal gravitation. Another observation made about the same time relates to the position of the winter solstice in the heavens; and it also corresponds to within a minute of a degree with the calculations of Laplace. Laplace considers this extraordinary conformity as an indubitable proof of the authenticity of those ancient observations. The golden age of Chinese astronomy extended from the reign of Fou-Hi to the year 480 B.C.,—that is, over a space of 2500 years. It is only, however, towards the latter part of this long period that the history of China becomes in any degree authentic; and the true date which must be assigned for the commencement of observations on which any reliance can be placed, is the year 722 B.C., that is, 25 years posterior to the era of Nabonassar. From that period to the year 400 B.C., Confucius reckons a series of 36 eclipses, and of these 31 have been verified by modern astronomers. After this the science fell into great neglect, notwithstanding the inveterate tenacity with which the Chinese in general adhere to their ancient customs. The decline of their astronomy is ascribed, whether justly or not, to the barbarous policy of the emperor Tsin-Chi-Hong-Ti, who, in the year 221 B.C., ordered all the books to be destroyed, excepting those only which related to agriculture, medicine, and astrology, the only sciences which he considered as being of any use to mankind. In this manner, it is said, the precious mass of astronomical observations and precepts which had been accumulating for ages was irretrievably lost.

On considering attentively the accounts which have been given of the Chinese astronomy, we find that it consisted only in the practice of observations which led to nothing more than the knowledge of a few isolated facts. The missionaries who were sent out by the Jesuits about the end of the 17th century, to whom we are indebted for what is known of the early history of China, either seduced by some appearances of truth, or thinking it prudent to conciliate the people whom they were attempting to convert, adopted their marvellous relations regarding the antiquity of their science, and spread them over Europe. As the history of the nation begins to become more authentic, their astronomy shrinks into its real, insignificant dimensions. Superstitiously attached to their ancient usages, and blindly adopting the habits of their ancestors, the Chinese continued to observe the heavens from century to century without making the slightest advances in theoretical knowledge. In later times they have adopted many improvements, for which they are entirely indebted to foreigners. During the time of the caliphs many Mahometans passed into China, carrying with them the astronomical methods and knowledge of the Arabians. The missionaries introduced the science of Europe; and the most that can be said in praise of the Chinese is, that their Government sometimes relaxed so far its spirit of jealousy and exclusion, as to afford protection to these strangers, adopt their arts, and place them at the head of the Mathematical Tribunal.

Indians. The astronomy of the Indians forms one of the most curious problems which the history of science presents, and one which, notwithstanding much discussion, still continues involved in great uncertainty. Of the science of the ancient nations of which we have already spoken, the accounts which have come down to our times are founded on conjecture and tradition; for few monuments remain to confirm or confute the glowing descriptions which authors have given of its high antiquity and great perfection. But the claims of the Indians rest on a more solid foundation. We are in possession of the tables from which they compute the eclipses and places of the planets, and of the methods by which they effect the computation; we have, in short, an Indian astronomy committed to writing, which represents the celestial phenomena with considerable exactness, and which, therefore, could only be produced by a people far advanced in science. But the difficulty the problem presents is the determination of the sources whence this science originated and the epoch of its existence—the question whether it was created by the people who now blindly follow its precepts without understanding its principles, or was communicated to them by another race of a more original genius through channels with which we are unacquainted. Some authors regard India as the cradle of all the sciences, particularly of astronomy, which they suppose to have been cultivated there from the remotest ages; others date the origin of the Indian astronomy from the period when Pythagoras travelled into that country, and carried thither the arts and sciences of the Greeks; a third opinion is, that astronomy was conveyed to India by the Arabians in the 9th century of our era, and that the Brahmins are only entitled to the humble merit of adapting the rules and practices of that people to their own peculiar methods of calculation.

Astronomy of the Greeks.

The origin of astronomy in Greece, as in other early nations, ascends beyond the period of authentic history.
Thales. The true foundations of Grecian science were laid by Thales, who was born at Miletus 640 years before our era. He formed a sect which has been distinguished by the title of the "Ionian School." His doctrines regarding astronomy contain a few truths which do honour to his sagacity and observation, though they are mixed with much error and absurdity. He taught that the stars are formed of fire; that the moon receives her light from the sun, and is invisible at her conjunctions, because she is hid in the sun's rays. He also taught the sphericity of the earth, which he placed at the centre of the universe. He divided the sphere into five zones, by the arctic and antarctic circles, and the two tropics; and held that the equator is cut obliquely by the ecliptic, and perpendicularly by the meridian. He is also said to have observed eclipses; and Herodotus relates that he predicted the famous one which put a stop to the war between the Medes and the Lydians. It does not appear, however, that he ventured to assign either the day or the month of the eclipse, so that his prediction must have been confined to the year. According to Callimachus, he determined the positions of the stars which form the Lesser Bear, by which the Phœnicians guided themselves in their voyages. It is difficult, however, to conceive how Thales, unacquainted with instruments, could determine the positions of stars with so much accuracy as to render any essential assistance to the navigator. It is probable that he only pointed out the configuration and some of the more brilliant stars of that constellation, among which he might remark that which is nearest the pole of the heavens. Thales was succeeded by Anaximander, to whom also is attributed a knowledge of the Anaximander sphere and of the zodiac. According to Diogenes Laertius, he, like his master Thales, supposed the earth to be spherical, and placed at the centre of the universe; but Plutarch ascribes to him the less philosophical opinion of its resemblance to a column. He supposed the sun to be of equal magnitude with the earth. He invented the gnomon, and placed one at Lacedæmon to observe the solstices and equinoxes. The circumstance which best entitles Anaximander to the gratitude of posterity is the invention of geographical charts. Anaximenes succeeded Anaximenes. Anaximander in the Ionian school, and maintained nearly the same doctrines. Pliny says he was the first who taught the art of constructing dials, an invention which, as we have just seen, has also been ascribed to Anaximander. These two philosophers probably revived the knowledge of an instrument, the use of which had been forgotten amidst the general rudeness and ignorance of their countrymen. Before their time the Greeks only marked the divisions of the day by the different lengths of the sun's shadow. Anaxagoras Anaxagoras. was the disciple and successor of Anaximenes. If this philosopher really entertained the ridiculous opinions ascribed to him by Plutarch, the Ionian school must rather have retrograded than advanced in sound philosophy from the time of Thales. He is said to have believed that the sun is a mass of red-hot iron, or of heated stone, somewhat bigger than the Peloponnesus, that the heaven is a vault of stones, which is prevented from tumbling only by the rapidity of its circular motion, and that the sun is prevented from advancing beyond the tropics by a thick and dense atmosphere, which forces him to retrace his course. These alleged opinions are probably greatly exaggerated; but it does not appear that Anaxagoras contributed much to extend the knowledge of the heavens. His disregard for the superstitious notions of his age brought its usual penal consequences. Having shown the reason of the eclipses of the moon, he was accused of ascribing to natural causes the attributes and power of the gods; and having taught the existence of only one God, he was accused of impiety and treason towards his country. Sentence of death was pronounced on the philosopher and all his family; and it required the powerful interest of his friend and disciple Pericles to obtain a commutation of the sentence into one of perpetual banishment.

While the Ionian sect was so successfully employed in cultivating and propagating a knowledge of nature in Greece, another, still more celebrated, was founded in Italy by Pythagoras. Pythagoras is said to have acquired in Pythagoras. Egypt the knowledge of the obliquity of the ecliptic, and of the identity of the morning and evening stars.

What he chiefly deserves to be commemorated for in the history of astronomy, is his philosophical doctrine regarding the motion of the earth. He taught publicly that the earth is placed at the centre of the universe; but among his chosen disciples he propagated the doctrine that the sun occupies the centre of the planetary world, and that the earth is a planet revolving round the sun. This system, which still retains his name, being called the old or Pythagorean system of the universe, is that which was revived by Copernicus. It is, however, only just to the latter to observe, that there is a vast difference between the bare statement of the possibility of a fact, and the demonstration of its existence by irrefragable arguments. Pythagoras having remarked the relation which subsists between the tone of a musical chord and the rapidity of its vibration, was led by analogy to extend the same relation to the planets, and to suppose that they emit sounds proportional to their respective distances, and form a celestial concert too melodious to affect the gross organs of mankind. Another fancy into which he was led by his passion for analogies, was the application of the five geometrical solids to the elements of the world. The cube symbolically represented the earth; the pyramid, fire; the octahedron, air; the icosahedron, or twenty-sided figure, water; and the dodecahedron, or figure with twelve faces, the exterior sphere of the universe. Pythagoras left no writings; and it is doubtful whether he really entertained many of the opinions and reveries which have usually been ascribed to him.

Philolaus. Philolaus of Crotona, a disciple of Pythagoras, embraced the doctrine of his master with regard to the revolution of the earth about the sun. He supposed the sun to be a disk of glass which reflects the light of the universe. He made the lunar month consist of $29\frac{1}{2}$ days, the lunar year

Nicetas. of 354 days, and the solar year of $365\frac{1}{2}$ days. Nicetas of Syracuse seems to have been the first who openly taught the Pythagorean system of the universe. Cicero, on the authority of Theophrastus, the ancient historian of astronomy, gives him the credit of maintaining that the apparent motion of the stars arises from the diurnal motion of the earth about its axis;[1] but this rational doctrine seems to have been first broached by Heraclides of Pontus, and Ecphantus, a disciple of Pythagoras.

Metonic cycle. The introduction of the Metonic cycle forms an era in the history of the early astronomy of Greece. The Chaldeans, as we have already stated, established several lunisolar periods; and the difficulty of reconciling the motions of the sun and moon, or of assigning a period at the end of which these two luminaries again occupy the same positions relatively to the stars, had long embarrassed those who had the care of regulating the festivals. Meton and Euctemon had the merit of first obviating this difficulty, at least for a time, for the motions of the sun and moon being incommensurable, no period can be assigned which will bring them back to precisely the same situations. These two astronomers formed a cycle of nineteen lunar years, twelve of which contained each 12 lunations, and the seven others each 13, which they intercalated among the former. It had long been known that the synodic month consisted of $29\frac{1}{2}$ days nearly, and in order to avoid the fraction, it had been usual to make the twelve synodic months, which compose the solar year, to consist of 29 and 30 days alternately, the former being called *deficient* and the latter *full* months. Meton made his period consist of 125 full and 110 deficient months, which gives 6940 days for the 235 lunations, and is nearly equal to 19 solar years. This cycle commenced on the 16th of July in the year 433 B.C. It was received with acclamation by the people assembled at the Olympic games, and adopted in all the cities and colonies of Greece. It was also engraved in golden letters on tables of brass, whence it received the appellation of the *golden number*, and has been the basis of the calendars of all the nations of modern Europe. It is still in ecclesiastical use, with such modifications as time has rendered necessary.

Eudoxus of Cnidus, about the year 370 B.C., obtained Eudoxus. great reputation as an astronomer. According to Pliny, he introduced the year of $365\frac{1}{4}$ days into Greece. Archimedes says that he supposed the diameter of the sun to be nine times greater than that of the moon, which shows that he had in some degree overcome the illusions of sense. The titles of three of his works have been preserved,—the *Period or Circumference of the Earth*, the *Phenomena*, and the *Mirror*. His observatory was still standing at Cnidus in the time of Strabo. He is noteworthy for his contempt of the Chaldean predictions, and for having contributed to separate true astronomy from the reveries of judicial astrology. Eudoxus seems to have been the first who attempted to give a mechanical explanation of the apparent motions of the planets. He supposed that each planet occupies a particular part of the heavens, and that the path which it describes is determined by the combined motion of several spheres performed in different directions. The sun and moon had each three spheres: one revolving round an axis which passes through the poles of the earth, and which occasions the diurnal motion; a second revolving round the poles of the ecliptic, in a contrary direction, and causing the annual and monthly revolutions; the third revolving in a direction perpendicular to the first, and causing the changes of declination. Each of the planets had a fourth sphere to explain the stations and retrogradations. As new inequalities and motions were discovered, new spheres were added, till the machinery became so complicated as to be altogether unintelligible.

Although Plato can hardly be cited as an astronomer, Plato. yet the progress of the science was accelerated by means of the lights struck out by his penetrating genius. He seems to have had just notions of the causes of eclipses; and he imagined that the celestial bodies originally moved in straight lines, but that gravity altered their directions, and compelled them to move in curves. He proposed to astronomers the problem of representing the courses of the stars and planets by circular and regular motions. Geometry was assiduously cultivated in the school of Plato; and on this account he claims a distinguished place among the promoters of true astronomy.

Astronomy is also under some obligations to Aristotle. Aristotle. In a treatise which he composed on this science, he recorded a number of observations which he had made; and, among others, mentions an occultation of Mars by the moon, and another of a star in the constellation Gemini by the planet Jupiter. As such phenomena are of rare occurrence, their observation proves that he had paid considerable attention to the planetary motions.

A great number of astronomers flourished about this time whose labours and observations prepared the way for the reformation of the science which was shortly after effected by Hipparchus. Helicon of Cyzicus is renowned Helicon. for the prediction of an eclipse, which took place, as Plutarch affirms, at the time announced. History records the names of only three individuals in ancient Greece who predicted eclipses,—Thales, Helicon, and Eudemus. Eudemus composed a history of astronomy, a fragment Eudemus. of which, consisting of only a few lines, is preserved by

---

[1] "Nicetas Syracusius, ut ait Theophrastus, cœlum, solem, lunam, stellas, supera denique omnia, stare censet; neque, præter terram, rem ullam in mundo moveri; quæ cum circum axem se summa celeritate convertat et torqueat, eadem effici omnia, quasi, stante terra, cœlum moveretur."—(Cicero, *Acad. Quæst.*, lib. iv. cap. 39.) Copernicus himself could not have stated the doctrine with greater precision.

Fabricius in the *Bibliotheca Græca.* In this it is mentioned that the axes of the ecliptic and equator are separated from each other by the side of a pentedecagon, which is equivalent to saying that they contain an angle of 24°. This is the first value which we find assigned by the Greeks to the obliquity of the ecliptic. It is given in round numbers, and may easily be supposed to contain an error of a quarter of a degree.

Calippus.

Calippus is celebrated for the period which he formed of four Metonic cycles. Having observed, by means of an eclipse of the moon which took place about six years before the death of Alexander, that the Metonic cycle contained an error of a fourth of a day, he introduced the period of 940 lunations, containing four Metonic cycles, diminished by one day. He likewise formed a collection of observations on the heliacal risings of the planets.

Theophrastus.

Theophrastus wrote a history of astronomy, and supposed the Milky Way to be produced by the imperfect junction of the two hemispheres, which allowed the light to penetrate from the firmament beyond.

Autolycus.

Autolycus of Pitane wrote two books,—one on the movable sphere, the other on the risings and settings of the stars. These are the most ancient of the astronomical works of the Greeks which have come down to our times.

Pytheas.

Pytheas of Marseilles, about the time of Alexander the Great, determined the length of the solstitial shadows in various countries by means of the gnomon. He found the shadows equal at Marseilles and Byzantium—a circumstance which does not give a favourable idea of the accuracy of his observations, inasmuch as the difference of the latitudes of the two places amounts to $2\frac{1}{4}$ degrees. The observation is, however, interesting, as it is the most ancient of the kind which has been preserved after that of Tcheou-Kong, and as it confirms the successive diminution of the obliquity of the ecliptic. Pytheas undertook several voyages for the purpose of obtaining geographical and astronomical information, and advanced northwards as far as Iceland. His accounts have been treated as fabulous by Strabo and Polybius, but the accuracy of the greater number of them has been confirmed by modern observation and experience. He was the first who distinguished the climates by the different lengths of the days and nights.

Astronomy in the School of Alexandria.

Aristillus and Timocharis.

The first astronomers of the Alexandrian school were Aristillus and Timocharis, who flourished under the first Ptolemy, about 300 years before Christ. The chief object of their labours was the determination of the relative positions of the principal stars of the zodiac instead of merely announcing their risings and settings, as had been the practice of the Orientals and the ancient Greeks. The observations of these two astronomers conducted Hipparchus to the important discovery of the precession of the equinoxes, and served as the basis of the theory which Ptolemy, some centuries afterwards, gave of that phenomenon.

Aristarchus.

Aristarchus of Samos, the next in order of the Alexandrian astronomers, composed a treatise *On the Magnitudes and Distances of the Sun and Moon*, which has been preserved to our times. In this treatise he describes an ingenious method which he employed to obtain the relative distances of the two luminaries. At the instant when the moon is dichotomised, that is, when the exact half of her disk appears to a spectator on the earth to be illuminated by the sun's light, the visual ray passing from the centre of the moon to the eye of the observer is perpendicular to the line which joins the centre of the moon and sun. At that instant, therefore, he measured the angular distance of the two bodies, and finding it to be 87°, he concluded, by the resolution of a right-angled triangle, that the distance of the sun is between eighteen and nineteen times greater than that of the moon. This method is perfectly correct in theory, but it is difficult to be assured of the exact instant of the moon's dichotomy, and in an angle of such magnitude a very small error greatly affects the result. The error of Aristarchus is very considerable, the true angle being about 87° 50′. The estimated distance of the sun is by consequence far too small; yet the determination, faulty as it was, contributed to expand greatly the existing notions relative to the boundaries of the universe, for the Pythagoreans had taught that the sun is only three, or at most three and a half times more distant than the moon. Another delicate observation made by Aristarchus was that of the magnitude of the sun's diameter, which, as we learn from Archimedes, he determined to be the 720th part of the circumference of the circle which the sun describes in his diurnal revolution. This estimate is not very far from the truth, and the observation is by no means an easy one. He embraced the doctrine of Pythagoras respecting the earth's motion, and appears to have entertained juster notions than any of the astronomers who preceded him, regarding the magnitude and extent of the universe. The treatise *On the Magnitudes and Distances* is published in the third volume of the works of Dr Wallis, with a Latin translation by Commandine, and some notes.

Eratosthenes.

Eratosthenes, the successor of Aristarchus, a native of Cyrene, was invited to Alexandria by Ptolemy Euergetes, who appointed him keeper of the royal library. He is supposed to have been the inventor of armillary spheres, a species of instrument extensively used by the ancient astronomers. By means of an instrument of this kind he observed the distance between the tropics to be to the whole circumference of a great circle as 11 to 83,—a ratio equivalent to 47° 42′ 39″, half of which gives 23° 51′ 19″·5 for the obliquity of the ecliptic. This is a very important observation, and confirms the gradual diminution of the obliquity as indicated by theory. Eratostheues is celebrated as the first who attempted, on correct principles, to determine the magnitude of the earth. Having remarked, by some means with which we are unacquainted, that Syene, the most southern of the cities of ancient Egypt, is situated nearly on the same meridian as Alexandria, he conceived the idea of determining the amplitude of the celestial arc intercepted between the zeniths of the two places, and of measuring at the same time their distance on the ground,—operations which would afford data for the determination of the whole length of the terrestrial meridian. Syene was known to be situated exactly under the tropic; for at the summer solstice the gnomon had no shadow, and the sun's rays illumined the bottom of a deep well in that city. On the day of the solstice he found the meridional distance of the sun from the zenith of Alexandria to be 7° 12′, or a fiftieth part of the circumference. It had also been ascertained by the *bematists* or surveyors of Alexander and the Ptolemies, that the itinerary distance between Alexandria and Syene was 5000 stadia; therefore $5000 \times 50 = 250{,}000$ stadia form the circumference of a great circle of the earth, or the length of the terrestrial meridian. Unfortunately, on account of the uncertainty respecting the length of the stadium here employed, we possess no means of estimating the degree of approximation afforded by this rude though ingenious attempt.

About this time the science of astronomy was enriched by the discoveries of some of the distinguished geometricians whose labours have so greatly extended the glory of the Alexandrian school.

Euclid.

Euclid, the celebrated author of the *Elements*, lived in the reign of the first Ptolemy. He composed a book on the sphere, which probably served as a model for future works of the same kind, and was the first who treated in a geometrical manner the phenomena of the different inclinations of the sphere.

Conon.

Conon of

Samos, the friend of Archimedes, collected the records of eclipses, which had been observed by the ancient Egyptians; and Callimachus ascribes to him the constellation of Berenice's hair. Archimedes Archimedes also claims a high rank among the cultivators of astronomy. His celebrated planetarium, which represented the motions of the sun, moon, planets, and starry sphere, has been a frequent theme of the praises of the poets:—

> Jura poli, rerumque fidem, legesque deorum,
> Ecce Syracosius transtulit arte senex."
> ·Claudian, *Epigr.* 18.

Apollonius. Apollonius of Perga solved the important problem of the stations and retrogradations of the planets by means of epicycles and deferents; and he is entitled to the glory of having formed the alliance between geometry and astronomy, which has been productive of the greatest advantages to both.

Hipparchus. Astronomy, which had as yet only consisted of a knowledge of isolated facts, acquired a systematic form, and almost a new existence, from the genius of Hipparchus, perhaps the greatest of all ancient philosophers in the sciences which are not purely speculative. This illustrious founder of astronomical science was born at Nicæa in Bithynia, and observed at Rhodes. Flamsteed and Cassini, probably misled by some ambiguous expressions of Ptolemy, have related that his observations were made at Alexandria; and this opinion seems generally to have been adopted by historians. The question has been examined carefully, and at considerable length, by Delambre (*Astronomie Ancienne*), who comes to the conclusion that there is no reason whatever to infer that Hipparchus ever saw Alexandria. Ptolemy, in reporting the observations of Hipparchus, supposed Rhodes and Alexandria to be situated on the same meridian, and consequently does not find it necessary to mention the place at which the observations were made. Hipparchus commenced his brilliant career by verifying the determination of the obliquity of the ecliptic made by Eratosthenes. He next directed his attention to the length of the tropical year. By comparing one of his own observations of the summer solstice with a similar one made by Aristarchus 140 years before, he found that the anciently received value of $365\frac{1}{4}$ days was too great by seven minutes. This leaves the tropical year a value still too great; but it is probable that the error arose from the inaccuracy of the observation of Aristarchus; for the observations of Hipparchus, compared with those of the moderns, make the length of the tropical year amount to 365 days, 5 hours, and 49 minutes, which is only 12 seconds greater than the truth. By a careful observation of the solstices and equinoxes, he discovered that the year is not divided by these points into four equal parts, the sun occupying $94\frac{1}{2}$ days in passing from the vernal equinox to the summer solstice, and only $92\frac{1}{2}$ from the same solstice to the equinox of autumn. The sun, consequently, remained 187 days in that part of the ecliptic which lies between the equator and the north pole, and therefore only about 178 in the other part. This observation led Hipparchus to the great discovery of the eccentricity of the solar orbit. He accounted for the apparent inequality of the sun's motion by supposing that the earth is not placed exactly at the centre of the circular orbit of the sun, and that, consequently, his distance from the earth is subject to variation. When the sun is at his greatest distance, he appears to move more slowly; and when he approaches nearer, his motion becomes more rapid. The distance of the earth from the centre of the orbit is called the eccentricity; it produces an equation between the real and apparent motions which is called the "equation of the centre." He determined the magnitude of this equation in terms of the radius of the ecliptic, and fixed the position of the line of the apsides, or that which joins the two opposite points of the orbit which are at the greatest and least distance from the earth. With these data he formed the first tables of the sun which are mentioned in the history of astronomy. The discovery of the eccentricity also led Hipparchus to that of the inequality of the lengths of the solar days at different seasons of the year. In the interval which elapses between the sun's passage over the meridian and his return to it the following day, the sun advances by his own proper motion towards the east nearly a degree. But the rate of this motion is unequal, varying between 57 and 61 minutes of a degree; and the accumulation of the inequalities forms what is called the equation of time, that is, the difference between the true time, as shown by the sun, and the mean time, shown by a well-regulated clock, the motions of which are equal and uniform.

The attention of Hipparchus was next directed to the motions of the moon; and on this subject his researches were attended with equal success. From the comparison of a great number of the most circumstantial and accurate observations of eclipses recorded by the Chaldeans, he was enabled to determine the period of the moon's revolution relatively to the stars, to the sun, to her nodes, and to her apogee. These determinations are among the most valuable results of ancient astronomy, inasmuch as they corroborate one of the finest theoretical deductions—the acceleration of the mean lunar motion—and thus furnish one of the most delicate tests of the truth of Newton's law of gravitation. It was indeed, by a comparison of the observations of Hipparchus with those of the Arabian and modern astronomers that Dr Halley was led to the discovery of that important phenomenon. Hipparchus also determined the eccentricity of the lunar orbit, and its inclination to the plane of the ecliptic; and the values which he assigned to these elements, making allowance for the evection and the inequalities of the moon's motion in latitude, are within a few minutes the same as those which are now observed. He had also an idea of the second inequality of the moon's motion, namely, the evection, and made all the necessary preparations for a discovery which was reserved for Ptolemy. He likewise approximated to the parallax of the moon, which he attempted to deduce from that of the sun, by determining the length of the frustum cut off from the cone of the terrestrial shadow by the moon, when she traverses it in her eclipses. From the parallax he concluded that the greatest and least distances of the moon are respectively equal to 78 and 67 semi-diameters of the earth, and that the distance of the sun is equal to 1300 of the same semi-diameters. The first of these determinations exceeds the truth, the second falls greatly short of it, the distance of the sun being nearly equal to 24,000 terrestrial semi-diameters. It may, however, be remarked that Ptolemy, who undertook to correct Hipparchus with regard to the parallax, deviated still farther from the truth.

The apparition of a new star in the time of Hipparchus induced him to undertake the formation of a catalogue of all the stars visible above his horizon, to fix their relative positions, and mark their configurations, in order that posterity might have the means of observing any changes which might in future take place in the state of the heavens. This arduous undertaking was rewarded by the important discovery of the precession of the equinoxes, one of the fundamental elements of astronomy. By comparing his own observations with those of Aristillus and Timocharis, he found that the first point of Aries, which, in the time of these astronomers, or 150 years before, corresponded with the vernal equinox, had advanced two degrees, according to the order of the signs, or at the rate of 48 seconds a year. This determination is not very far from the truth; for, according to modern observations, the rate of the precession is about 50·1 seconds annually. His catalogue contained 1080 stars,—not, as has sometimes been erroneously stated, 1022, the number in that of Ptolemy, in which the nebulous and some obscure stars are omitted. He also commenced a series of observations to furnish his successors with the means of forming a theory of the planets. Hipparchus likewise invented the planisphere, or method of representing the starry firmament on a plane surface, which afforded the means of solving the problems of spherical trigonometry in a manner often more exact and more convenient than the globe itself. He was the first who demonstrated the methods of calculating triangles, whether rectilineal or spherical; and he constructed a table of chords, from which he drew nearly the same advantages as we derive at present from the tables of sines. Geography is also indebted to him for the happy idea of fixing the position of places on the earth by means of their latitudes and longitudes; and he was the first who determined the longitude by the eclipses of the moon.

After the death of Hipparchus nearly three centuries elapsed before any successor arose worthy of the name. During this long period astronomy made no essential advancement. Some rough observations, scarcely superior to those of the Chaldeans, and a few meagre treatises, are the only monuments which exist to testify that science had not fallen into utter oblivion in an age so fertile of poets and orators. Geminus and Cleomedes wrote treatises, which have been preserved to our times; Agrippa and Menelaus are said to have observed; the Roman calendar was reformed by Julius Cæsar and the Egyptian astronomer Sosigenes; and Posidonius measured a degree, and remarked that the laws of the tides depend on the motions of the sun and moon.

Ptolemy.

Ptolemy was born at Ptolemais in Egypt, and flourished at Alexandria about the 130th year of our era, under the reigns of Hadrian and Antoninus. This illustrious ornament of the Alexandrian school is entitled by his own discoveries to the high rank among astronomers which has universally been assigned to him; but the most signal service which he conferred on science was the collection and arrangement of the ancient observations. Out of these materials he formed the Μεγάλη Σύνταξις, or *Great Composition*, a collection which exhibits a complete view of the state of astronomy in the time of Ptolemy, and which contains the germ of most of the methods in use at the present day. The hypothesis which Ptolemy adopted for the purpose of explaining the apparent motions, was that which had been followed by Hipparchus. To account for the uniform circular motion, Apollonius imagined the ingenious apparatus of epicycles and deferents; and Hipparchus advanced a step farther, by placing the centre of the sun's circle at a small distance from the earth. Ptolemy adopted both hypotheses, and supposed the planet to describe an epicycle by a uniform revolution in a circle, the centre of which was carried forward uniformly in an eccentric round the earth. By means of these suppositions, and by assigning proper relations between the radii of the epicycle and deferent circle, and also between the velocity of the planet and the centre of its epicycle, he was enabled to represent with tolerable accuracy the apparent motions of the planets, and particularly the phenomena of the stations and retrogradations, which formed the principal object of the researches of the ancient astronomers. The notions of Apollonius and Hipparchus were thus reduced to a systematic form, and the proportions of the eccentrics and epicycles of all the planets assigned, by Ptolemy; on which account the system has been generally ascribed to him, and has obtained the name of the *Ptolemaic System* of the universe.

The most important discovery which astronomy owes to Ptolemy is that of the evection of the moon. Hipparchus had discovered the first lunar inequality, or the equation of the centre, which serves to correct the mean motion at the syzygies, and had also remarked the necessity of another correction for the quadratures. He even undertook a set of observations, with a view to ascertain its amount and its law; but death put a stop to his labours before he had brought them to a successful issue. Ptolemy completed the investigation, and discovered that the eccentricity of the lunar orbit is itself subject to an annual variation, depending on the motion of the line of the apsides. The variation of the position of the apsides produces an inequality of the moon's motion in her quarters, which has been technically denominated the evection. The equation given by Ptolemy, though of course empirical, is remarkably exact.

Ptolemy employed a very simple process for determining the moon's parallax, which was probably suggested to him by the situation of Alexandria, where he observed. He determined the latitude of a place a little to the south of that city, over the zenith of which the moon was observed to pass when her northern declination was the greatest possible. But when the moon is in the zenith, or in the same straight line with the observer and the centre of the earth, she has no parallax; consequently the obliquity of the ecliptic and the latitude of the station being known, the moon's greatest northern latitude was also determined. The next step was to observe the moon's meridian altitude fifteen days after the first observation, when her southern latitude was necessarily the greatest possible. This observation gave the *apparent* altitude of the moon, but her greatest northern and southern declinations being supposed equal, her *true* altitude, as seen from the centre of the earth, was easily computed from the previous observation, and the difference between the true and apparent altitudes gave the amount of the parallax.

The observations of Hipparchus relative to the motion of the stars in longitude, or the regression of the equinoctial points, were confirmed by Ptolemy, although he mistook his amount, and diminished a quantity which Hipparchus had already estimated too low. According to Hipparchus the regression is at the rate of two degrees in 150 years. Ptolemy reduced it to one degree in 90 years. This disagreement would seem to indicate an error of more than a degree in the observations, which can with difficulty be admitted, considering the accordance which subsists among the different observations cited by Ptolemy in support of his own determination. For this and some other reasons Ptolemy has been accused of altering the observations of Hipparchus, and accommodating them to his own theory; and there would appear to be but too just grounds for the imputation. The error with regard to the regression may, however, have arisen from the circumstance, that Hipparchus had assigned too great a value to the length of the year, whence the motion of the sun with regard to the equinoxes would be made too slow, and the longitudes employed by Ptolemy consequently diminished.

Ptolemy has been called The Prince of Astronomers,—a title which may perhaps be justified by the universal and long-continued prevalence of his system, but to which he has no claim from the number or value of his own observations. After a laborious and minute examination of the *Almagest*, Delambre doubts whether anything is contained in that great work, beyond the author's own statement, from which it can be decisively inferred that Ptolemy ever observed at all. He, indeed, frequently makes mention of observations made by himself; but his solar tables, rate of the precession, eclipses, determination of the moon's motion and parallax, and above all, his catalogue of stars, render it impossible to doubt that the greater part of the results which he has given as observations are merely computed from the tables of Hipparchus. He never in any instance cites a single observation more than is just necessary for the object he has immediately in view, and consequently, by precluding all comparison of one observation with another, has deprived us of the means even of guessing at the probable amount of the errors of his solar, lunar, and planetary tables. If an astronomer, as Delambre justly remarks, were to adopt the same course at the present day, he would be certain of forfeiting all claim to confidence; but Ptolemy stood alone; he had neither judges nor rivals; and now no one condescends to calculate the few observations he has left us. His catalogue contains only 1022 stars, and is therefore less extensive than that of Hipparchus, but it is exceedingly valuable on account of its details.

Astronomy of the Arabians.

The most celebrated of the Arabian astronomers was Albategni, or Muhammed Ben Geber Al-Batani, so called from Batan, a city of Mesopotamia, where he was born about 850. He was a prince of Syria, and resided at Rakka in Mesopotamia; but many of his observations were made at Antioch. Having studied the *Syntaxis* of Ptolemy, and made himself acquainted with the methods practised by the Greek astronomers, he began to observe, and soon found that the places assigned to many of the stars in Ptolemy's tables were considerably different from their actual situations, in consequence of the error which the latter had committed with regard to the precession of the equinoxes. Albategni measured the rate of the precession with greater accuracy than had been done by Ptolemy; and he had still better success in his attempt to determine the eccentricity of the solar orbit, his value of which differs extremely little from that which results from modern observations. In assigning the length of the year, however, he fell into an error of more than two minutes; but this proceeded, as has been shown by Dr Halley, from too great confidence in the observations of Ptolemy. Albategni also remarked that the place of the sun's apogee is not immovable, as former astronomers had supposed, but that it advances at a slow rate, according to the order of the signs,—a discovery which has been confirmed by the theory of gravitation. A new set of astronomical tables, more accurate than those of Ptolemy, likewise resulted from the indefatigable labours of Albategni; and his observations, important in themselves, are doubly interesting on account of the fact that they form a link of connection between those of the astronomers of Alexandria and of modern Europe. The works of Albategni were published in 1537 under the title of *De Scientia Stellarum.*

Ibn-Junis, who flourished at the beginning of the 11th century, constructed a set of tables, and composed a sort of celestial history, in which he has recorded numerous observations of his own and of other astronomers belonging to the same country. This work, imperfectly known through some extracts, long excited the curiosity of astronomers, as it was supposed to contain observations tending to establish the acceleration of the mean motion of the moon. A manuscript copy of it, belonging to the University of Leyden, was, in 1804, transmitted to the French Institute, and translated by Professor Caussin. It contains 28 observations of eclipses from the year 829 to 1004; seven observations of the equinoxes; one of the summer solstice; one of the obliquity of the ecliptic made at Damascus, by which the value of that element is found to be 23° 35′; and likewise a portion of tables of the sun and moon, with some other matter illustrative of the state of astronomy among the Arabians. The observations which regard the acceleration of the mean lunar motion are two eclipses of the sun and one of the moon, observed by Ibn-Junis, near Cairo, in the years 977, 978, and 979, and they agree with theory in confirming the existence of that phenomenon.

Ulugh Begh. Ulugh Begh, a Tartar prince, and grandson of the great Tamerlane, not only encouraged the study of astronomy, but was himself a diligent and successful observer. At Samarcand, the capital of his dominions, he established an academy of astronomers, and caused the most magnificent instruments to be constructed for their use. By means of a gnomon 180 feet in height, he determined the obliquity of the ecliptic to be 23° 30′ 20″, the precession of the equinoxes at 1° in 70 years, and obtained elements for the construction of tables which have been found to be scarcely inferior in accuracy to those of Tycho Brahe. The ancient astronomy had produced only one catalogue of the fixed stars, that of Hipparchus. Ulugh Begh has the honour of having formed a second, after an interval of sixteen centuries.

Revival of Astronomy in Europe.

After the death of Ulugh Begh, astronomy received no farther accessions in the East. But the seeds of knowledge had now begun to take root in a more propitious soil, and Europe, destined to carry the development of the human energies to its fullest extent, began to awake from the lethargy in which it had continued during so many ages.

Purbach. The 14th century produced no astronomer from whose labours the science gained any accessions. George Purbach, or Beurbach, so named from a small town in Austria, where he was born in 1423, obtained great celebrity as a professor. He studied at Vienna, and after giving proofs of exceptional talent, he travelled into Italy, where he was favourably received by Cardinal de Cusa, who himself cultivated astronomy. On his return to Vienna he undertook a translation of the *Almagest;* and although ignorant both of Greek and Arabic, his perfect acquaintance with the subject enabled him to correct many errors which had been introduced through the carelesness or ignorance of former translators. Purbach had the good fortune to form a disciple who executed many of the plans which had been interrupted by his premature death. This was the celebrated John Müller of Königsberg, better known by the name of Regiomontanus. Attracted to Vienna in his youth by the great reputation of Purbach, he continued to study there during ten years, and on the death of his master repaired to Rome for the purpose of acquiring the Greek language, and of making himself, through it, acquainted with the *Almagest.* At Rome he continued his observations, and translated into Latin the works of Ptolemy, the *Conics* of Apollonius, and some other treatises of ancient science. In 1471 he retired to Nuremberg, where, with the aid of Bernard Walther, a wealthy burgess, he founded an observatory and furnished it with excellent instruments principally of his own invention, by means of which he was enabled to detect many errors in the ancient tables. After the death of Regiomontanus, Walther continued to observe at Nuremberg during thirty years. His observations were collected by order of the senate of Nuremberg, and published by Schöner in 1544, a second time by Snellius, and, lastly, along with those of Tycho Brahe. In 1484 Walther began to make use of clocks, then a recent invention, to measure time in celestial observations. He was also the first who employed the planet Venus in determining the longitudes of the stars.

Regiomontanus

Nuremberg had the honour of producing another astronomer of some celebrity. John Werner was the first who explained the method, which was afterwards brought into general use by Maskelyne, of finding the longitude at sea, by observing the distance between a fixed star and the moon. He published some mathematical and geographical treatises, and made a number of observations to determine the obliquity of the ecliptic and the precession of the equinoxes.

We come now to the period of the overthrow of the Ptolemaic system and the total renovation of the science of astronomy, which was due to the labours of Copernicus. Copernicus. The system which is associated with the name of Copernicus is now so familiar to every one, that it is almost unnecessary to describe it. The heaven, composed of stars perfectly at rest, occupies the remotest bounds of space, then the orbit of Saturn, next Jupiter, Mars, the Earth (accompanied by its moon), Venus, Mercury, and, lastly, the Sun immovable at the centre. By this arrangement the stations and retrogradations of the planets became simple mathematical corollaries, following from the differences of the radii of their orbits and their unequal motions. The diurnal rotation of the earth explained more simply and rationally the apparent daily revolution of the heavens; and the precession of the equinoxes was referred to a small variation in the inclination of the earth's axis to the plane of the ecliptic. But the simplicity of the system, and its consequent probability, were the only arguments which Copernicus was able to bring forward in proof of its reality. The motion of the earth can, indeed, never be made an object of ocular demonstration; but after Richer's discovery of the diminution of gravity towards the equator, it was impossible to doubt longer of the existence of its rotatory motion; and when Roemer had measured the velocity of light, and Bradley observed the phenomena of aberration, the evidences of its annual revolution were rendered equally convincing. Great, however, as were the merits of Copernicus, it must be acknowledged that he left his system in a very imperfect state. After the example of the ancients, he assumed as an axiom the uniform circular motion of the planets; and as the only motions which are observed are in a state of incessant variation, he was obliged, in order to explain the inequalities, to suppose a different centre to each of his orbits. The sun was placed *within* the orbit of each of the planets, but not in the centre of any of them, consequently he had no other office to perform than to distribute light and heat; being excluded from any influence on the system, he became as it were a stranger to all the motions. Yet notwithstanding these and other imperfections, the establishment of the doctrine of the earth's motion, with an evidence which dissipated the illusions of sense, was a great step towards the true knowledge of the planetary system; and when we consider the ignorance and prejudices of the age, we cannot hesitate to admit his claim to a high rank among philosophers. But whether the actual services which he rendered to astronomy are commensurate with the great fame he has obtained, may admit of doubt. He revived an ancient opinion opposed to the prejudices and religious dogmas of his times, and fortified it with new and strong, though not absolutely convincing, proofs. It seldom happens, however, with regard to those sciences which ultimately appeal to experience, that general reasoning, even of the soundest kind, tends much to their real advancement; and there is little reason for thinking that astronomy would have been less perfect, or that any discoveries since made in it would have been retarded a single day, even if Copernicus had never lived. His great merit, like that of Lord Bacon, consists in the sound views which he took of nature, and in advancing so far before the general attainments of his age. For the events of his life see COPERNICUS.

Tycho Brahe. Tycho Brahe stands next in chronological order on the roll of those who have contributed to the progress of astronomy. As an indefatigable and skilful observer, he is justly considered as far superior to any astronomer who had preceded him since the revival of the science in Europe. His ample fortune gave him the means of procuring the best instruments which the age could produce; and by his ingenuity and persevering application, he was admirably qualified to employ them to the best advantage. He computed the first table of refractions, and if it extended only to 45°, the reason was, that the effects of refraction, at a higher altitude, were altogether insensible to his instruments. His solar tables were brought to so great a degree of exactness, that he affirms he could never detect an error in them exceeding a quarter of a minute; but there is reason to suspect some exaggeration in this statement, particularly as Cassini, a century after, with much better means, could scarcely answer for errors of a whole minute. He contributed greatly to the improvement of the lunar tables, and detected a considerable inequality in the moon's motion in longitude, to which he gave the name of the *Variation*, by which it has ever since been distinguished. He also discovered an equation in latitude similar to the evection which had been observed by Hipparchus, and fixed its amount with great accuracy. He remarked the fourth inequality of the moon in longitude, although he failed in his attempt to ascertain its amount, or assign its law. He represented the inequalities of the motions of the nodes, and in the inclination of the lunar orbit, by the motion of the pole of that orbit in a small circle round the pole of the ecliptic. He demonstrated that the region of the comets is far beyond the orbit of the moon, and determined the relative and absolute positions of 777 fixed stars with scrupulous exactness, which gave his catalogue an immense superiority over those of Hipparchus and Ulugh Begh; and he left to his successors a regular series of observations of the planets, amassed for the purpose of establishing the truth of his own system, but of which Kepler made a better use by employing them to establish the system of Copernicus. For an account of his life, see BRAHE, TYCHO.

Kepler. The great mass of accurate observations accumulated by Tycho furnished the materials out of which his disciple Kepler may be said to have constructed the edifice of the universe. The observations of the Danish astronomer had furnished the latter with the means of establishing with certainty the truth or inaccuracy of the various hypotheses which he successively imagined; and the diligence with which he laboured in comparing and calculating these observations during 20 years, was finally rewarded by some of the most important discoveries which had yet been made in astronomy. Deceived by an opinion which had been adopted by Copernicus, and had never been called in question by the ancients, that all the celestial motions are performed in circles, he long fruitlessly endeavoured to represent by that hypothesis the irregular motions of Mars; and after having computed with incredible labour the observations of seven oppositions of that planet, he at length discovered that the motions could only be accurately represented by supposing the planet to move in an ellipse, having the sun in one of its foci. Having arrived at this important result, he next proceeded to consider the angular motion of the planet, and finding that it was not uniform in respect of any point situated within the orbit, he concluded that uniform motion, till then universally received as an axiom, had no existence in nature. He perceived, however, that the areas described in equal times by the radius vector of the planet, at its greatest and least distances, were equal; and subsequent observations enabled him to demonstrate that this equality extended to every point of the orbit. It was therefore discovered that Mars moves in an elliptic orbit, of which the sun occupies a focus, and in such a manner, that the area described by a line drawn from the centre of the planet to that of the sun is always proportional to the time of description. The same conclusions he found to be true in respect of the orbit of the earth; and therefore he could no longer hesitate to extend them by analogy to the other plants. These are two of the three general principles which are known by the name of the 'Laws of Kepler."

It was some years later before Kepler arrived at the knowledge of the analogy which subsists between the distances of the several planets from the sun, and the periods in which they complete their revolutions. To the discovery of this analogy he attached the greatest importance, and regarded all his other labours as incomplete without it. After having imagined numberless hypotheses, it at last occurred to him to compare the different powers of the numbers which express the distances and times of revolutions; and he found, that the squares of the periodic times of the planets are always in the same proportion as the cubes of their mean distances from the sun. This is the third law of Kepler. He demonstrated it to be true of all the planets then known. It has been found to be equally true in regard to those which have been since discovered, and likewise to prevail in the systems of the satellites of Jupiter and Saturn. It is, indeed, as can be shown mathematically, a necessary consequence of the law of gravitation—directly as the masses, and inversely as the squares of the distances.

By these brilliant discoveries, the solar system was reduced to that degree of beautiful simplicity which had been conceived by Copernicus, but from which that great astronomer had found himself constrained to depart. The sun could not occupy the common centre of the circular orbits, but his place is in the common focus of the elliptic orbits of all the planets; and it is to this focus that every motion is to be referred, and from this that every distance is to be measured. The discovery of the elliptic motion, of the proportionality of the areas to the times, and the method of dividing an ellipse, by straight lines drawn from the focus to the periphery, into segments having a given ratio, formed the solution of a problem which had been the constant object of the labours of all astronomera from Ptolemy to Tycho, namely, to assign the place of a planet at any instant of time whatever. The tables which he computed for the elliptic motions form the model of those in present use. Some additions have been made in consequence of perturbations which the geometry of Kepler was inadequate to estimate, and which were only partially detected by the genius of Newton. It has been considered matter of surprise that Kepler did not think of extending the laws of the elliptic motion to the comets. Prepossessed with the idea that they never return after their passage to the sun, he imagined that it would only be a waste of time to attempt the calculation of the orbits of bodies which had so transitory an existence. He supposed the tail to be produced by the action of the solar rays, which, in traversing the body of the comet, continually carry off the most subtile particles, so that the whole mass must be ultimately annihilated by the successive detachment of the particles. He therefore neglected to study their motions, and left to others a share of the glory resulting from the discovery of the true paths of the celestial bodies.

The observations of eclipses had formed the principal object of the earliest astronomers, but it was Kepler who first showed the practical advantages which may be derived from them, by giving an example of the method of calculating a difference of meridians from an eclipse of the sun. The method extends to occultations of the stars, and is deservedly considered as the best we possess for determining geographical longitudes and correcting the tables. He composed a work on optics, replete with new and interesting views, and gave the first idea of the telescope with two convex glasses, which has since been advantageously substituted for that of Galileo. Prompt to seize every happy idea of his contemporaries, he perceived with delight the advantages which practical astronomy would derive from the new invention of the logarithms, and he immediately constructed a table, from which the logarithms of the natural numbers, sines, and tangents could be taken at once.

Kepler was not merely an observer and calculator, he inquired with great diligence into the physical causes of every phenomenon, and made a near approach to the discovery of that great principle which maintains and regulates the planetary motions. He possessed some very sound and accurate notions of the nature of gravity, but unfortunately conceived it to diminish simply in proportion to the distance, although he had demonstrated that the intensity of light is reciprocally proportional to the surface over which it is spread, or inversely as the square of the distance from the luminous body. In his famous work *De Stella Martis*, which contains the discovery of the laws of the planetary motions, he distinctly states that gravity is a corporeal affection, reciprocal between two bodies of the same kind, which tends, like the action of the magnet, to bring them together, so that when the earth attracts a stone, the stone at the same time attracts the earth, but by a force feebler in proportion as it contains a smaller quantity of matter. Further, if the moon and the earth were not retained in their respective orbits by an animal or other equipollent force, the earth would mount towards the moon one fifty-fourth part of the interval which separates them, and the moon would descend the fifty-three remaining parts, supposing each to have the same density. He likewise very clearly explains the cause of the tides in the following passage:—"If the earth ceased to attract its waters, the whole sea would mount up and unite itself with the moon. The sphere of the attracting force of the moon extends even to the earth, and draws the waters towards the torrid zone, so that they rise to the point which has the moon in the zenith." It is not difficult to imagine how much these views must have contributed to the immortal discovery of Newton. (See KEPLER.)

Contemporary with Kepler was the illustrious Galileo, Galileo.
whose discoveries, being of a more popular nature, and far more striking and intelligible to the generality of mankind, had a much greater immediate effect on the opinions of the age, and in hastening the revolution which was soon about to change the whole face of physics and astronomy. While residing at Venice, he heard it reported that Metius, a Dutch optician, had discovered a certain combination of lenses, by means of which distant objects were approximated to the sight. This vague and scanty intelligence sufficed to excite the curiosity of Galileo, who immediately set about inquiring into the means whereby such an effect could be produced. His researches were attended with prompt success, and on the following day he had a telescope which magnified about three times. It was formed by the combination of two lenses, a plano-convex and plano-concave, fitted in a leaden tube. In a second trial he obtained one which magnified seven or eight times; and subsequent essays enabled him to increase the magnifying power to 32 times. On directing his telescope to the moon, he perceived numerous inequalities on her surface, the diversified appearances of which led him to conclude almost with certainty that the moon is an opaque body similar to the earth, and reflecting the light of the sun unequally, in consequence of her superficial asperities. The planet Venus exhibited phases perfectly similar to those of the moon. These phases had been formerly announced by Copernicus as a necessary consequence of

his system; and the actual discovery of their existence made it impossible to doubt the revolution of Venus round the sun. He detected the four satellites or moons of Jupiter, and, in honour of his patron, gave them the name of the "Medicean Stars." The discovery of these little bodies circulating round the huge orb of Jupiter afforded him a strong analogical proof of the annual revolution of the earth, accompanied by its moon. He perceived spots on the disk of the sun, from the motions of which he deduced the rotation of that body about its axis in the space of 27 days. The singular appearances of Saturn were beheld by him with no less pleasure than astonishment. His telescope was not sufficiently powerful to separate the ring from the body of the planet; and to explain the appearances he supposed Saturn to be composed of three stars almost in contact with one another. These discoveries proved that the substances of the celestial bodies are similar to that of the earth, and demolished the Aristotelian doctrine of their divine essence and incorruptible nature. They enlarged the ideas of mankind respecting the planetary system, and furnished the most convincing arguments in favour of the doctrines of Copernicus.

Science is indebted to Galileo for two other discoveries of a different kind, less brilliant perhaps, but of far greater importance than those which we have yet enumerated. These are the isochronism of the vibrations of the pendulum, and the law of the acceleration of falling bodies. His telescopic discoveries could not have remained long unknown; in fact, with the exception of those of the phases of Venus, and of the triple form of Saturn, they were all fiercely disputed, even during his own lifetime. It is now universally admitted that he was the first who discovered the satellites of Jupiter, and the spots of the sun; but the very circumstance of other claimants to these discoveries having arisen, proves that they were within the reach of ordinary observers. For an account of his eventful life see GALILEO.

While astronomy was making these rapid advances in the hands of Kepler and Galileo, an event occurred in Scotland which contributed, though less directly, no less powerfully, to the acceleration of its progress. This was the invention of logarithms by Lord Napier, baron of Merchiston; "an admirable artifice," says Laplace, "which by reducing to a few days the labour of many months, doubles the life of the astronomer, and spares him the errors and disgust inseparable from long calculations,—an invention of which the human mind has the more reason to be proud, inasmuch as it was derived exclusively from its own resources." It may be added, that without this, or some equivalent artifice, the computations rendered necessary by more correct observations would far exceed the limits of human patience or industry, and astronomy could never have acquired that precision and accuracy by which it is now distinguished above all the other branches of human knowledge.

The same epoch presents to us a great number of excellent observers, who, although they did not produce any revolution in the state of astronomy, still rendered it useful service. Scheiner is celebrated for his observations of the solar spots, and his disputes with Galileo. John Bayer of Augsburg published a description of the constellations, accompanied by maps, in which the stars are marked by Greek letters,—a simple idea, which has been universally adopted. Lansberg, a Flemish mathematician, published in 1632 a set of astronomical tables, which, though filled with inaccuracies, rendered good service to science by

Horrox. apprising Horrox of the transit of Venus over the sun's disk, which that young astronomer and his friend Crabtree had the satisfaction of observing on the 24th of November 1639. They were the first who ever witnessed that rare phenomenon. Snellius is celebrated for his measurement of the earth. Gassendi, who had the merit along with Descartes of hastening the downfall of the Aristotelian philosophy in France, made some useful observations, particularly one of a transit of Mercury in 1631. His works, which fill six folio volumes, abound with curious and useful researches. Riccioli, a Jesuit, born at Ferrara in 1598, contributed to the progress of astronomy, not so much by his own discoveries, as by collecting and rendering an account of those of others. He rejected the system of Copernicus, and was more zealous in maintaining the doctrines of the church than in investigating nature; but his works form a vast repertory of useful information. His *Novum Almagestum* is a collection of the observations, opinions, and physical explanations of the phenomena, together with all the methods of computation then known. He was assisted in his labours by Grimaldi, who discovered the inflection of light, and he gave to the principal spots of the moon the names which are now used by astronomers.

Hevelius. The most accurate observations that were ever made prior to the adaptation of the telescope to astronomical instruments were those of Hevelius, a rich citizen of Dantzic, who devoted his life and a large fortune to the service of astronomy. Having fitted up an observatory, and furnished it with the best instruments which could be procured, he commenced a course of observations, which he followed assiduously upwards of forty years. In his *Selenographia* he has given an accurate description of the face and spots of the moon, accompanied with excellent delineations of her appearance in her different phases and librations. The idea of making drawings of the different phases of the moon had previously occurred to Gassendi and Peiresc, but they had not been able to execute the project; indeed, the difficulty attending it was such, that it occupied Hevelius, who was an excellent draughtsman, as well as observer, during a great number of years. Hevelius made an immense number of researches on comets; and finding that the observations could not be represented by rectilinear or circular orbits, he supposed them to move in parabolas. During a temporary absence from Dantzic he had the misfortune to lose, in a great fire which occurred in the city, his observatory, instruments, manuscripts, and almost the entire copy of the second volume of his *Machina Cœlestis*, which contained the results of his protracted labours. He was now in his old age, but his zeal did not give way under the terrible calamity. He patiently recommenced all his calculations, reconstructed tables of the sun, and prepared for publication his *Firmamentum Sobiescianum*, or celestial chart, which did not appear till after his death. Towards the latter part of his life the use of telescopic sights began to be generally adopted. Hevelius, however, resisted the innovation, and continued to employ plain sights. This preference given to the ancient method by so skilful an observer induced Dr Halley to visit him at Dantzic, for the purpose of ascertaining, by a comparison of observations made at the same time and place, which of the two methods gave the most correct results. Dr Halley observed with the telescope, and Hevelius with his own instruments; but such was the dexterity he had acquired through long practice, that the difference of their observations seldom amounted to more than a few seconds, and in no case to so much as a minute. Notwithstanding this agreement, it is to be regretted that Hevelius did not adopt the new method; for, on account of the greater precision given to instruments by the use of the telescope, his observations, which were made without it, cannot now be admitted in the construction of tables, and consequently are for the most part useless to astronomy.

Few individuals have rendered more important services

Huyghens. to science than Huyghens. His improvement of the telescope and his application of the pendulum to clocks were valuable additions to the machinery of astronomical investigation. By means of his telescopes he discovered that the extraordinary appearance exhibited by Saturn was occasioned by a ring surrounding the body of the planet, and inclined to the ecliptic in an angle which he estimated at 21°. He published his observations of this planet in a work entitled *Systema Saturnium*, which still shows some traces of that species of reasoning from final causes which so greatly disfigures the writings of Kepler. For example, on discovering the satellite, he conceived that as the number of satellites now equalled the number of planets, it was vain to look for more, the equality being necessary to the harmony of the system. He lived, however, to witness the discovery of four more satellites belonging to the same planet. (See HUYGHENS.)

The application of telescopes and micrometers to graduated instruments forms an important epoch in the history of astronomy. This happy improvement was first brought into use by Picard in 1667. Morin, indeed, had applied a telescope to the quadrant so early as 1634, and perceived the stars in full day in 1635. In 1669 Picard began to observe the stars on the meridian in the day time, with a quadrant, to which, in concert with Azout, he had applied an astronomical telescope having cross wires in its focus. Huyghens invented the plate micrometer in 1650; Malvasia that with the fixed wires in 1662; and Azout that with the movable wire in 1666. (See Delambre, *Astronomie du Moyen Age*, p. 618; note by Bouvard.) It is principally to these ingenious inventions and the fine application of the pendulum to clocks by Huyghens in 1656, that we must attribute the rapid progress since made in practical astronomy, and the extreme precision of modern observations. Picard was also the first who introduced the modern method of determining the right ascensions of the stars, by observing their meridional passages, and employed the pendulum for that purpose. He likewise introduced the method of corresponding altitudes, and is entitled to be regarded as the founder of modern astronomy in France. Roemer, the friend and pupil of Picard, discovered the progressive motion of light in 1675, and measured its velocity by means of the eclipses of Jupiter's satellites. He was the first who erected a transit instrument, which gave a new accuracy to observations of right ascension.

The Royal Observatory of Paris was completed in 1670, and its direction intrusted to Dominic Cassini, who enriched astronomy with a great number of valuable observations and new discoveries. He determined the motions of Jupiter's satellites from observations of their eclipses, and constructed tables of them, which were found to be remarkably exact. He observed that the ring of Saturn is double, and discovered four of the satellites of that planet. He also determined the rotation of Jupiter and Mars, and made a number of observations on Venus with the same view. He observed the zodiacal light, and made a near approximation to the parallax of the sun. We also owe to him the first table of refractions calculated on correct principles, and a complete theory of the libration of the moon. Galileo had only observed the libration in latitude; Hevelius explained the libration in longitude, by supposing that the moon always presents the same face to the centre of her orbit, of which the earth occupies a focus. Cassini made the important remark, that the axis of rotation of the moon is inclined to the ecliptic, and that its nodes coincide with those of the lunar orbit, so that the poles of the orbit, ecliptic, and equator of the moon, are on the same circle of latitude, the pole of the ecliptic being situated between the other two. Though the greater number of these discoveries were only of secondary importance, Cassini, nevertheless, obtained an extraordinary reputation. Lalande remarks, that in his hand astronomy underwent the most signal revolutions, and that his name is, in France, almost synonymous with that of creator of the science. Delambre has, however, expressed a different and far more accurate view of the real services of Cassini in the following terms:—

> "The revolution in astronomy was brought about by Copernicus, by the laws of Kepler, by the pendulum of Huyghens, by the micrometers of Azout and Picard, by the sectors and mural of Picard and his method of corresponding altitudes, by the transit instruments of Roemer; and Cassini appears to us an entire stranger to all these innovations. He followed another route he devoted a long life to painful observations, which at last deprived him of sight. Let us not refuse him the praise which he has so well merited, but let us reserve a place in our esteem for labours less brilliant perhaps, but of greater and more permanent utility, and which evince at least equal talent and sagacity."

Cassini was assisted in his observations by his nephew, James Philip Maraldi, who determined the regression of the nodes, and the progressive motion of the apsides of the orbit of Jupiter. This astronomer also corrected the theory of Mars, and observed the sun's parallax. He rejected the hypothesis of the progressive motion of light, as being insufficient to explain the inequalities of Jupiter's satellites; and he conceived the design of forming a new catalogue of the stars, which, however, was never executed. He died in 1729. M[illegible]

There is no period in the history of mankind so distinguished by great and important discoveries, or so remarkable for the rapid development of the human intellect, as the 17th century. We have already noticed the invention of the pendulum, and its application to regulate the motion of timekeepers; the invention of the telescope, bringing within the range of vision the phenomena of new worlds; of logarithms, by which computations are so much abridged; and of the mechanical contrivances for measuring minute angles in the heavens. The same century witnessed the application of algebra to geometry, the discovery of the laws of the planetary motions, the infinitesimal calculus, the acceleration of falling bodies, the sublime theory of central forces, and the great principle of gravitation which connects the celestial orbs, and regulates the motions which it had been the business of the astronomer to observe since the earliest ages of the world. The service which the discovery of these primary laws rendered to the progress of astronomy can scarcely be exaggerated. Many of the inequalities of the planetary motions, in consequence of their minuteness and the slowness with which they occur, could not have been detected by observation; others might perhaps have been perceived, but we should still have been ignorant whether their constant accumulation might not ultimately change the state of the system, and, by destroying all confidence in the tables, demolish the fabric which had been reared at such a vast expense of time and labour. But when these inequalities are detected by theory, and separated from the mean motions with which they were blended, it becomes an object of the highest interest to confirm their existence by the most delicate and accurate observations. Hence, a more refined practice has constantly followed every theoretical discovery. Besides, it is the perfection of theory, and not the mere knowledge of isolated facts, which gives astronomy its greatest value in the eyes of the philosopher. Numerous and important as its applications are, they have but a subordinate interest, in comparison with the knowledge of those general laws to which every particle of matter in the universe is subject, and by the discovery of which man has penetrated so deeply into the mysteries of nature. Progress during the 17th century.

By the discovery of the law of gravitation, Newton laid the foundations of physical astronomy; and by the consequences which he deduced from that law, he proceeded far in Newton.

the erection of the superstructure. He showed that the motions of all the bodies of the planetary system are regulated by its influence; he determined the figure of the earth on the supposition of its homogeneity; he gave a theory of the tides, discovered the cause of the precession of the equinoxes, and determined some of the principal lunar inequalities and planetary perturbations. Many of his theories were left in an imperfect state; for it is not in matters of science that it is given to the same individual to invent and bring to perfection: their complete development required that several subsidiary sciences should be farther advanced; but it has been the triumph of his system, that every subsequent discovery has only tended to strengthen and confirm it.

While physical astronomy was undergoing a complete revolution in the hands of Newton, the practical part was receiving great improvement from Flamsteed, the first astronomer royal, who conducted the Greenwich Observatory. This celebrated institution, from which so many important discoveries have emanated, was erected under the reign of Charles II., in 1675. Flamsteed was appointed to it in 1676, and continued with indefatigable zeal to discharge the duties of the office during the long period of 33 years. In the course of this time he made an immense number of excellent observations, the results of which are given in the *Historia Cœlestis*, the first edition of which was published in 1712, at the expense of Prince George of Denmark, the husband of Queen Anne. The second appeared in 1723, some time after the death of the author, in three volumes folio. The first volume contains the observations which he made, first at Derby, and afterwards at Greenwich, of the fixed stars, planets, comets, spots of the sun, and Jupiter's satellites. The second volume contains the transits of the planets and stars over the meridian, and the places of the planets deduced from these observations. The third contains a historical notice, in which he gives a description of the instruments used by Tycho and himself; catalogues of fixed stars by Ptolemy, Ulugh Begh, Tycho, the landgrave of Hesse, and Hevelius; together with the British Catalogue, containing the places of 2884 stars. The labours of Flamsteed were, however, confined entirely to the practical part of astronomy. He made no improvements in theory; but he is entitled to the merit of having been the first who brought into common use the method of simultaneously observing the right ascension of the sun and a star, a method by means of which the determination of the positions of the stars is reduced to the observation of meridional transits and altitudes. He was likewise the first who explained the true principles of the equation of time; and he improved the lunar tables by introducing into them the annual equation which had been suggested by Horrox.

Halley. Flamsteed was succeeded in the observatory by Halley, who held a prominent place among English astronomers. From early youth he applied himself with ardour to the study of mathematics and astronomy; and having procured a few instruments, he began to make observations, by which he was led to remark the inaccuracy of the tables of Jupiter and Saturn. In his 19th year he published a direct and geometrical method of finding the eccentricities and aphelia of the orbits of the planets; and in the year following he undertook a voyage to St Helena, with a view to form a catalogue of the stars in the southern hemisphere. The station was unfortunately chosen, for, owing to the incessant rains and foggy atmosphere of that island, he was able to determine the places of only 360 stars in the course of a whole year. He had, however, the satisfaction of observing a transit of Mercury over the sun's disk, a phenomenon which suggested to him the important idea, that the transits of the inferior planets might be advantageously employed in determining one of the most essential elements of the planetary system, viz., the parallax of the sun, and consequently the diameters of the orbits. The method has since been successfully employed in the case of Venus: the transits of Mercury, though much more frequent, are not so well adapted to the purpose. The other additions which he made to astronomical knowledge are chiefly recorded in his *Synopsis Astronomiæ Cometicæ*,—a work abounding in profound and original views, and which, in respect of theory, formed perhaps the most remarkable accession to the science that had been made since the time of Kepler. In this work he revived an ancient opinion, that the comets belong to the solar system, and move in very eccentric orbits round the sun, returning after stated but long intervals. He also ventured to predict that the comet of 1681 would again return to its perihelion in 1759,—the first prediction of the kind ever verified. In 1720 Halley was appointed to succeed Flamsteed in the Royal Observatory; and though then in the 64th year of his age, he undertook, with a view to improve the lunar theory, to observe the moon through a whole revolution of her nodes, erroneously supposing that after such a revolution the errors of the tables would again appear in the same order. He was the first who, by a comparison of ancient and modern observations, remarked the acceleration of the mean motion of the moon, and thus called the attention of mathematicians to an important and curious phenomenon, the physical cause of which was at length detected by the powerful analysis of Laplace. He was also the first who pointed out the secular inequalities of Jupiter and Saturn, occasioned by their mutual perturbations,—a theory that formed the subject of several profound memoirs of Euler and Lagrange, and for the complete development of which astronomy is likewise indebted to Laplace. (See HALLEY.)

The discoveries of Bradley, who succeeded Halley as astronomer royal, form a memorable epoch in the history of the science. Bradley. It was reserved to him to give the theoretical explanation of a singular motion of the polar star which had been first observed by Picard, who had remarked that the inequality was annual, and amounted to about 40 seconds, but had been unable to refer it to any law. Hooke, in 1674, a few years after the observations of Picard, imagined that he had discovered a parallax in some of the stars, and Flamsteed, following the ideas of Hooke, explained, by means of parallax, the minute changes of position which he had observed in Polaris and some circumpolar stars. Manfredi and Cassini demonstrated the error of Flamsteed, but were not more successful in their attempts to explain the motion in question. Samuel Molyneux conceived the idea of verifying all that had been said respecting the supposed parallaxes, and for this purpose commenced a series of observations at Kew, with an excellent 24-feet sector constructed by Graham. Bradley, who happened at that time to reside at Kew, took part in these observations, the result of which was, that the remarks of Picard were confirmed beyond the possibility of doubt. It was, however, abundantly evident that the apparent motions observed were not connected in any manner with parallax, it therefore became an object of the greatest interest to determine their physical cause, and assign their law and period. The first idea that occurred was to inquire whether they arose from a change of position in the earth's axis; but this supposition was found to be inadequate to the explanation of the phenomena. Molyneux having been in the meantime appointed a lord of the Admiralty, the observations were discontinued at Kew; they were, however, shortly after resumed by Bradley at Wanstead, with a smaller but more convenient instrument, and after they had been continued several years, it was found that the star (γ Draconis) on which they were principally made, appeared to describe annually a small ellipse, the transverse axis of which amounted to 40″. This was an important determination; for the ellipse afforded the means of computing at all times the aberration of any star whatever, whether in longitude, latitude, declination, or right ascension. Bradley also pointed out the physical cause of the aberration, and demonstrated that it resulted from the combination of the motion of light with the annual motion of the earth. This very remarkable and important discovery was made in 1728.

Bradley, anxious to verify his ingenious theory, continued his observations, and soon felt the difficulty that had so much embarrassed Picard. The places of the stars, calculated according to his formula for the aberration, could not be reconciled with the observations. The errors continued to augment during nine years, after which they went on diminishing during the nine years following. This inequality, of which the period, like that of the nodes of the moon, was 18 years, was readily explained by supposing a slight oscillation of the earth's axis, occasioned by the action of the moon on the protuberant parts surrounding the equator of the terrestrial spheroid. After assiduously observing its effects during twenty years, Bradley found that the phenomena could be accurately represented by giving the pole of the equator a retrograde motion about its mean place in an ellipse whose axes are 18″ and 16″, and completing its revolution in the period of 18 years. This result was communicated to the Royal Society in 1748. To these two grand discoveries of Bradley, the aberration and nutation, modern astronomy is greatly indebted for its accuracy and precision; and as Delambre remarks, they assure to their author a distinguished place, after Hipparchus and Kepler, among the astronomers of all ages and all countries. For the biography see BRADLEY, JAMES.

While England was witnessing the brilliant discoveries of Bradley, France produced a number of excellent astronomers, by whose successful labours every department of the science was signally promoted. Among these Lacaille is distinguished, both by his scientific zeal and the importance of his observations. In 1751 he undertook a voyage to the Cape of Good Hope, the primary objects of which were to determine the sun's parallax, by means of observations of the parallaxes of Mars and Venus, while similar observations were made in Europe, and to form a catalogue of the southern circumpolar stars. No undertaking for the benefit of science was ever more successfully executed. In the course of a single year, Lacaille, without assistance, observed upwards of 10,000 stars, situated between the tropic of Capricorn and the pole, and computed the places of 1942 of them. The details of his observations were published in the *Cœlum Australe Stelliferum*, which appeared in 1763. During the same time he measured a degree of the meridian, and made numerous observations of the moon simultaneous with those of Lalande (who observed at Berlin), in order to determine the moon's parallax by means of direct observations made at the extremities of a meridional arc of upwards of 85° Astronomy is likewise indebted to Lacaille for a table of refractions, which he computed from a comparison of above 300 observations made at the Cape and at Paris. In 1757 he published his *Astronomiæ Fundamenta*, in which he gave rules and tables for computing the apparent motions of the stars, which continued to be employed till Lambert supplied the corrections depending on the nutation, and Delambre those depending on the aberration.

The question of the figure of the earth furnished ample materials for the practical as well as the speculative astronomer during the 18th century. The results of the measurement of the meridian by Cassini were at variance with the theories of Newton and Huyghens; and the Academy of Sciences resolved on making a decisive experiment by the actual measurement of the lengths of two degrees, one at the equator, and another in as high a latitude as could be reached. In the year 1735, three astronomers—Godin, Bouguer, and La Condamine—were commissioned by the French Government to accomplish the first of these objects in Peru; and the year following, Maupertuis, Clairaut, Camus, and Lemonnier went to Lapland to execute the second under the polar circle. Notwithstanding the greater difficulties they had to contend with, the first party were the more successful; but the result of both operations established the compression of the earth at the poles Bouguer published the details of the Peruvian measurement in an admirable work *On the Figure of the Earth*, in which he has also inserted an account of a great number of experiments made by him in the same country to determine the length of the seconds' pendulum, and the effects of the attraction of mountains on the plumb-line. Bouguer is likewise the author of an excellent treatise on light. The details of the labours of numerous other observers in the various countries of Europe will be found under their respective names. Here it is sufficient to indicate briefly the share each had in the development of the science.

Delisle Delisle formed a school of astronomy in Russia, and left a method of computing the heliocentric places of the sun's spots and of Mercury and Venus in their transits over the sun's disk, and likewise of determining, by means of the stereographic projection, the directions of their paths when they enter and leave the disk. **Wargentin** Wargentin, secretary of the Academy of Sciences of Stockholm, devoted himself specially to the correction of the tables of the satellites of Jupiter. The theory of the satellites was not then far advanced; but when theory failed him, he profited by the remarks of others and by his own reflections, and endeavoured by repeated trials to find empirical equations capable of reconciling the tables with the best observations. By confining himself almost exclusively to this subject he acquired a high reputation, and was ranked among the first astronomers of an epoch which abounds in great names. His tables of the satellites have, on account of their superior accuracy, been employed in determining the masses and other elements, which serve as the basis of the analytical theories.

Maskelyne, the second English astronomer royal after Bradley, was appointed, in 1761, to observe the transit of Venus at the island of St Helena, and endeavour to verify the existence of a small parallax of the star Sirius, which seemed to be indicated by the observations of Lacaille at the Cape. Unfortunately, the state of the weather prevented him from observing the transit; and his observations on Sirius were abandoned in consequence of the discovery of a defect in the zenith sector which he had carried out with him for the purpose of making the observations in question. The main objects of his voyage were thus frustrated; but some indirect advantages, notably the improvement of the sector by Ramsden, resulted from it, which compensated in some measure for the disappointment. At St Helena he made several interesting observations of the tides, the variation of the compass, the moon's horary parallaxes, &c. In going out and returning home he paid particular attention to the different methods of finding the longitude at sea, and practised that which depends on observations of the lunar distances from known stars, taken with Hadley's sextant, or some other reflecting instrument. In the year 1765 he was appointed astronomer royal, and soon after recommended to the Board of Longitude the general adoption in the navy of the lunar method of finding the longitude, and proposed that tables for facilitating that method should be calculated and published in the *Nautical Almanac*. This recommendation was adopted, and the *Nautical Almanac* continued to be published under his superintendence during forty-eight successive years.

W. Herschel. Sir William Herschel, born in Hanover in 1738, has rendered his name immortal by the discovery of a new planet beyond the orbit of Saturn, and thereby doubling the ancient boundaries of the solar system. Having settled in England at Bath, he began to devote his leisure to the construction of telescopes and the polishing of reflecting mirrors. Endowed with equal skill and patience, he soon obtained instruments superior to any that had been known before, by means of which he was led to the most brilliant discoveries that have been made in the heavens since the time of Galileo. Being employed in making a review of the sky with a powerful telescope, he perceived, on the 13th of March 1781, near the feet of Gemini, a star of the fifth magnitude, having a disk perfectly well defined, and differing in appearance from other stars which afforded the same quantity of light. On observing it with a telescope whose magnifying power was 932, he perceived its diameter was enlarged while that of the stars underwent no change. These circumstances were sufficient to draw his attention to the star, and nothing more was requisite to enable him speedily to discover that it had a slow motion. He at first supposed it was a comet, and acquainted Dr Maskelyne with the discovery. The circumstance was soon made known at Paris; and it was gradually perceived, that as the distance of the star did not sensibly vary, it was necessary to regard it as a seventh planet. Herschel, in honour of his patron George III., gave it the name of the *Georgium Sidus;* but the mythological appellation of Uranus has prevailed. On the 11th of January 1787 he discovered two satellites revolving round the new planet, and subsequently found that it was accompanied by four others. It was soon noticed that Uranus had been observed by Flamsteed, Mayer, and Lemonnier, who had each supposed it to be one of the fixed stars. Their observations enabled Delambre to correct the elements of the orbit, and calculate tables of its motion. By means of his powerful telescopes Herschel determined the figure and rotation of Saturn, discovered the parallel belts on his surface, and perceived that the ring is double. In 1789 he discovered two new satellites belonging to this planet, revolving near the ring. From some appearances indicated by the fixed stars, Herschel was led to conclude that the whole solar system is in motion about some distant centre, and that its direction is at present towards the constellation Hercules,—a conclusion which recent investigations have verified. His observations on nebulæ and double stars opened up a new field of research, boundless in extent, and interesting by reason of the variety of the objects it presents to the attention of the observer. The extraordinary activity with which he pursued his favourite occupations is attested by 67 memoirs communicated by him from time to time to the Royal Society.

Delambre. Few individuals have contributed so much to the perfection of modern astronomy as Delambre, for many years perpetual secretary of the Academy of Sciences. Associated with Mechain, he was employed during the troubles of the French Revolution in measuring the meridian from Dunkirk to Barcelona,—a labour which was prosecuted with admirable zeal in the face of innumerable difficulties, and even dangers of the most formidable kind. By an immense number of excellent observations he determined the constants which enter into the formulæ deduced from theory by the profound researches of Lagrange and Laplace, and also formed a set of tables much more exact than any that had appeared before them. His *Astronomie Théorique et Pratique*, in three quarto volumes, contains the best rules and methods which have yet been devised for the guidance of the practical astronomer; and his *Histoire*, in six large quarto volumes, gives an account of every successive improvement which has been made in the science, and a full abstract of every work of celebrity which has been written respecting it, from the first rude observations of the Greeks to the end of the last century. It is invaluable to the historian, and will always attest the profound learning and laborious research of its author.

Piazzi. The observatory which was established at Palermo about the year 1790, under the active superintendence of Piazzi, holds a distinguished rank among the similar institutions of Europe. Piazzi, born in 1746, took the habit of the religious order of the *Theatins* at Milan, and finished his noviciate in the convent of St Anthony. Among his preceptors he had the advantage of counting Tiraboschi, Beccaria, Le Sœur, and Jacquier; and from these illustrious masters he speedily acquired a taste for mathematics and astronomy. After holding several professorships in the colleges of the Jesuits at Rome and Ravenna, he was appointed, in 1780, professor of the higher mathematics in the Academy of Palermo. A few years after his appointment he obtained from the prince of Caramanico, viceroy of the island, permission to found an observatory, and undertook a voyage to France and England in order to provide the instruments necessary for the new establishment. Having procured a vertical circle, a transit, and some other instruments from Ramsden, he returned to Palermo and commenced his observations. His first care was to prepare a new catalogue of stars, the exact positions of which he justly considered as the basis of all true astronomy. In prosecuting this object he did not content himself with a single observation, but before he fixed the position of any star, observed it several times successively; and, by this laborious but accurate method, he constructed his first great catalogue of 6748 stars, which was crowned by the Academy of Sciences of France, and received with admiration by the astronomers of all countries. His constant practice of repeating his observations led to another brilliant result, the discovery of an eighth planet. On the 1st of January 1801, Piazzi, searching for the star 87 of the catalogue of Mayer, cursorily observed a small star of the eighth magnitude between Aries and Taurus. On the following day he remarked that the star had changed its position, and accordingly supposed it to be a comet. He communicated his observations to Oriani, who, seeing that this luminous point had no nebulosity like the comets, and that it had been stationary and retrograded within comparatively small limits like the planets, computed its elements on the hypothesis of a circular orbit. He found that this hypothesis agreed with the observations, and other astronomers soon confirmed its accuracy. He gave the planet the name of *Ceres Ferdinandea*, in honour of Ferdinand, king of Naples, in whose dominions he had made the discovery, and who proposed to commemorate the event by a gold medal, struck with the effigy of the astronomer, but Piazzi, preferring the interests of science to vain honours which could add nothing to his glory, requested that the money destined for this purpose should be employed in the purchase of an equatorial, which was still wanting to his observatory. In 1814 he published a new catalogue, extended to 7646 stars,—a splendid monument of indefatigable zeal and activity. He made an uninterrupted series of solstitial observations from 1791 to 1816, for the purpose of determining the obliquity of the ecliptic, which, compared with those of Bradley, Mayer, and Lacaille, in 1750, give a diminution of 44″ in a year.

We will conclude this part of the article by briefly adverting to the researches of some illustrious mathematicians who have developed the theory of Newton, and by whose investigations physical astronomy has been raised to its present position. Although the law of gravitation, as proposed by Newton, had from the first been admitted by all the most eminent astronomers of Britain, it was for a long time either opposed or neglected on the Continent. In fact, great improvements were required both in analysis and mechanics before it admitted of other applications than had been made by its great author, or could be regarded as anything more than a plausible hypothesis. Newton demonstrated that if two bodies only were projected in space, mutually attracting each other with forces proportional directly to their masses and inversely to the squares of their distance, they would each accurately describe an ellipse round the common centre of gravity, and the spaces described by the straight line joining that centre and the moving body would be proportional to the time of description, according to the second law of Kepler. But when it is attempted to apply Newton's law to the case of the solar system, great difficulties immediately present themselves. Any one planet in the system is not only attracted by the sun, but also, though in a much smaller degree, by all the other planets, in consequence of which it is compelled to deviate from the elliptic path which it would pursue in virtue of the sun's attraction alone. Now, the calculation of the effects of this disturbing force was the problem which geometers had to resolve. In its most general form it greatly transcends the power of analysis, but there are particular cases of it (and those, too, the cases presented by nature), in which, by reason of certain limitations in the conditions, it is possible to obtain an approximate solution to any required degree of exactness. For example, the Sun, Moon, and Earth form in a manner a system by themselves, which is very slightly affected by the aggregate attractions of the other planets. In the same way the Sun, Jupiter, and Saturn, form another system, in which the motions are very little influenced by the action of any other body. In these two cases, then, the number of bodies to be taken into consideration is only three; and in this restricted form, the problem, celebrated in the history of analysis under the denomination of "the Problem of Three Bodies," is susceptible of being treated mathematically. With the hope of improving the lunar tables, and of completing the investigations which Newton had commenced in the *Principia*, three distinguished geometers—Clairaut, D'Alembert, and Euler—about the middle of the last century, undertook, simultaneously, and without the knowledge of each other, the investigation of the problem of three bodies, and commenced that series of brilliant discoveries which our own times have seen completed.

Clairaut. Clairaut's solution of the problem of three bodies was presented to the Academy of Sciences in 1747, and was applied to the case of the moon. From this solution he deduced with great facility, not only the inequality of the variation, which Newton had obtained by the application of a more complicated though very ingenious method, but also the evection, the annual equation, and many other inequalities which Newton had not succeeded in connecting with his theory. It happened, however, curiously enough, that in the calculation of one effect of the disturbing force, namely, the progression of the moon's apogee, Clairaut was led into an error which produced a result that threatened to overturn the system of gravitation. The error consisted in the omission of some of the terms of the series expressing the quantity in question, which he wrongly supposed to have only an insensible value; and by reason of this omission, his first approximation gave only half of the observed progressive motion of the apogee. As this result was confirmed by D'Alembert and Euler, who had both fallen into the same error, it seemed to follow, as a necessary consequence, either that the phenomenon depended on some other cause than the disturbing force of the sun, or that the law of gravitation was not exactly proportional to the inverse square of the distance. The triumph which this result gave to the Cartesians was not of long duration. Clairaut soon perceived the cause of his error, and by repeating the process, and carrying the approximations farther, he found the computed to agree exactly with the observed progression,—a result which had the effect of dissipating for ever all doubt respecting the law of gravitation. The researches of Clairaut were followed by a set of lunar tables, much more correct than any which had been previously computed.

The return of the comet of 1682, which Halley had predicted for the end of 1758 or beginning of 1759, afforded an excellent opportunity for putting to the test both the theory of gravitation and the power of the new calculus. Clairaut applied his solution of the problem of three bodies to the perturbations which this comet sustained from Jupiter and Saturn, and, after calculations of enormous labour, announced to the Academy of Sciences, in November 1758, that the comet would return in the beginning of the following year, and pass through its perihelion about the 15th of April. It returned according to the prediction, but passed its perihelion on the 13th of March. The correction of an error of computation reduced the difference to nineteen days, and if Clairaut had been aware of the existence of the planet Uranus, he might have come still nearer the truth.

Besides these important researches on the system of the universe, Clairaut composed an admirable little treatise on the figure of the earth, in which he gave the differential equations, till then unknown, of the equilibrium of fluids, whether homogeneous or heterogeneous, supposing an attractive force, following any law whatever, to exist among the molecules. He applied these equations to the earth; demonstrated that the elliptic figure satisfies the conditions of equilibrium; and assigned the ellipticity of the different strata of which the earth may be supposed to be formed, together with the law of gravitation at the exterior surface. He likewise discovered the important theorem which establishes a relation between the oblateness of the terrestrial spheroid and the increase of gravitation towards the poles, on every supposition which can be imagined relative to the interior construction of the earth. By means of this theorem the ellipticity of the spheroid is deduced from observations of the lengths of the seconds pendulum at different points of the earth's surface.

D'Alembert. D'Alembert, as has already been mentioned, presented a solution of the problem of three bodies to the Academy of Sciences at the same time as Clairaut. In the year 1749 he published his treatise on the precession of the equinoxes,—a work remarkable in the history of analysis and mechanics. By means of his newly invented "Calculus of Partial Differences," and the discovery of a fertile principle in dynamics, he determined from theory the rate of the precession, rather more than 50″ in a year. He also determined the nutation of the earth's axis, which had been discovered by Bradley, and assigned the ratio of the axes of the small ellipse which the true pole of the earth describes around its mean place in the same time in which the nodes of the lunar orbit complete a revolution. The solution of this problem led to the determination of the ratio of the attractive forces of the sun and moon, which D'Alembert found to be that of seven to three very nearly; whence he inferred that the mass of the earth is 70 times greater than that of the moon. He proved likewise that the precession and nutation are the same in every hypo thesis concerning the interior constitution of the earth. In 1754 he published the first two volumes of his *Researches on the System of the World.* In this work he applied the formulæ by which he had calculated the motions of the moon to the motions of the planets disturbed by their mutual attraction, and pointed out the simplest method of determining the perturbations of the motions of a planet occasioned by the action of its own satellites. D'Alembert also treated the subject of the figure of the earth in a much more general manner than had been done by Clairaut, who had confined his investigations to the case of a spheroid of revolution. He determined the attraction of a spheroid of small eccentricity, whose surface can be represented by an algebraic equation of any order whatever, even supposing the spheroid to be composed of strata of different densities.

The first memoir of Euler on the planetary perturbations was transmitted to the secretary of the Academy of Sciences in July 1747, some months before Clairaut and D'Alembert had communicated their solutions of the problem of three bodies, and it carried off the prize which the academy had offered for the analytical theory of the motions of Jupiter and Saturn. In this memoir Euler gave the differential equations of the elements of the disturbed planet, but withheld the analysis by which he had been conducted to them. This analysis, however, he subsequently expanded in two memoirs, the first of which appeared in the Berlin Memoirs in 1749, and the second in those of St Petersburg in 1750. Of these supplementary memoirs the first is remarkable on several accounts. It contains the first example of a method which has been fruitful of important consequences—namely, that of the variation of the arbitrary constants in differential equations, and the development of the radical quantity which expresses the distance between two planets in a series of angles, multiples of the elongations. The expressions which he gave for the several terms of this series were simple and elegant; and he demonstrated a curious relation subsisting among any three consecutive terms, by means of which all the terms of the series may be calculated from the first two. He was thus enabled to develop the perturbing forces in terms of the sines and cosines of angles increasing with the time, and thereby to surmount a very great analytical difficulty. Notwithstanding, however, the great merit of Euler's memoir, several of the formulæ expressing the secular and periodic inequalities were found to be inaccurate; and in order to procure a correction of these errors, and give greater perfection to so important a theory, the academy again proposed the same subject for the prize of 1752. This prize was also carried off by Euler. In the memoir which he presented on this occasion, he considered simultaneously the motions of Jupiter and Saturn, and determined, in the first instance, the amount of their various inequalities, independently of the consideration of the eccentricities of their orbits. Pushing the approximations farther, and having regard to the inequalities depending on the eccentricities, he arrived at a most important result relative to the periodic nature of the inequalities occasioned by the mutual perturbations of the planets; which laid the foundation of the subsequent discovery by Lagrange and Laplace of the permanent stability of the planetary system. He demonstrated that the eccentricities and places of the aphelia of Jupiter and Saturn are subject to constant variation, which is confined, however, within certain fixed limits; and he computed that the elements of the orbits of the two planets recover their original values after a lapse of about 30,000 years. In the year 1756 the Academy of Sciences crowned a third memoir of Euler on the same subject as the two former, namely, the inequalities of the motions of the planets produced by their reciprocal attractions. This memoir analytically considered is also of great value. The method which he followed and illustrated has since been generally adopted in researches of the same nature, and consists in regarding as variable, in consequence of the disturbing forces, the six elements of the elliptic motion, viz.,—1*st*, the major axis of the orbit, which, by the law of Kepler, gives the ratio of the differential of the mean longitude to the element of the time; 2*d*, the epoch of this longitude; 3*d*, the eccentricity of the orbit; 4*th*, the motion of the aphelion; 5*th*, the inclination of the orbit to a given fixed plane; and, 6*th*, the longitude of the node. By considering separately the variations introduced into each of these elements by the disturbing forces, Euler obtained some important results; but even in this memoir his theory was not rendered complete. He did not consider the variation of the epoch; and the expression which he gave for the motion of the aphelion did not include that part of it which depends on the ratio of the eccentricities of the orbits of the disturbed and disturbing planet. Besides, the third memoir, like the two former, contained several errors of computation, which, by leading to results known to be wrong, probably prevented the author himself from being aware of the full value of the ingenious methods of procedure which he had described. Euler concluded this important memoir by making an extended application of his formulæ to the orbit of the earth as disturbed by the action of the planets. From some probable suppositions, first employed by Newton, relative to the ratios of the masses of the planets to that of the sun, he determined the variation of the obliquity of the ecliptic at 48″ in a century,—a result which agrees well with observation. By this determination the secular variation of the obliquity of the ecliptic, which had been regarded by Lahire, Lemonnier, D'Alembert, and other eminent astronomers as uncertain, was placed beyond doubt. The three memoirs which we have mentioned contain the principal part of Euler's labours on the perturbations; but physical astronomy is indebted to him for many other researches. He gave a solution of the problem of the precession of the equinoxes, and made several important steps in the lunar theory, with which he seems to have occupied himself before he undertook the investigation of the planetary perturbations. In the year 1772, when entirely blind, he directed his son, Albert Euler, and two illustrious pupils, Krafft and Lexell, in the composition of a work of enormous labour on the same subject, which was undertaken with a view to discover the cause of the moon's acceleration. This work was concluded with a set of lunar tables deduced entirely from theory; but they were found to be far inferior to those of Mayer, and in some respects hardly equal to those of Clairaut.

The first theory of Euler formed the basis of the excellent lunar tables which were calculated by Tobias Mayer, **Mayer.** and first published in the Memoirs of the Academy of Göttingen in 1753. Mayer was a skilful astronomer, and determined the co-efficients of the arguments of the different lunar inequalities from his own observations. He continued to correct and improve his tables till the time of his death, which happened in 1762, when a copy of them, containing his last corrections, was presented by his widow to the Board of Longitude in London. They were printed along with the author's lunar theory in 1765. Subsequently, the Board of Longitude directed Mason, who had been assistant to Bradley, to revise them, under the superintendence of Dr Maskelyne. Mason compared them with about 1200 of Bradley's observations, corrected the co-efficients of Mayer, and introduced some new equations which had been indicated by that astronomer, but which he had considered as too uncertain, or of too small a value, to render it necessary to load his tables with them.

Mayer's tables, thus corrected, were published in 1784, and for a long time continued to be the most accurate that had appeared.

The solution of the problem of three bodies by Clairaut, D'Alembert, and Euler, gave rise to many other important works relative to the theory of the moon, into the merits of which, however, our limits will not permit us to enter. Thomas Simpson, Walmesley, Frisi, Lambert, Schulze, and Matthew Stewart treated the subject with more or less success; but the complete explication of the theory of the lunar and planetary perturbations was reserved for two mathematicians, whose discoveries perfected the theory of gravitation, and explained the last inequalities which remained to be accounted for in the celestial motions,—Lagrange and Laplace.

Lagrange.

In the year 1764, the Academy of Sciences of Paris, which had so successfully promoted the great efforts that had already been made to perfect the theory of attraction, proposed for the subject of a prize the theory of the libration of the moon. Lagrange had the honour of carrying off the prize; but although he treated the subject in a manner altogether new, and with extraordinary analytical skill, he did not on this occasion arrive at a complete solution of the problem. In 1766 he obtained another prize for a theory of Jupiter's satellites. In the admirable memoir which Lagrange presented to the academy on this subject, he included in the differential equations of the disturbed motion of a satellite the attracting force of the sun, as well as of all the other satellites, and thus, in fact, had to consider a problem of six bodies. His analysis of this problem is remarkable, inasmuch as it contained the first general method which was given for determining the variations which the mutual attractions of the satellites produce in the forms and positions of their orbits, and pointed out the plan which has since been so successfully followed in the treatment of similar questions.

Of all the grand discoveries by which the name of Lagrange has been immortalised, the most remarkable is that of the invariability of the mean distances of the planets from the sun. We have already mentioned that Euler had perceived that the inequalities of Jupiter and Saturn, in consequence of their mutual actions, are ultimately compensated, though after a very long period. In prosecuting this subject, which Euler had left imperfect, Laplace had discovered that, on neglecting the fourth powers in the expressions of the eccentricities and inclinations of the orbits and the squares of the disturbing masses, the mean motions of the planets and their mean distances from the sun are invariable. In a short memoir of 14 pages, which appeared among those of the Berlin Academy for 1776, Lagrange demonstrated generally, and by a very simple and luminous analysis, that whatever powers of the eccentricities and inclinations are included in the calculation of the perturbations, no secular inequality, or term proportional to the time, can possibly enter into the expression of the greater axis of the orbit, or, consequently, into the mean motion connected with it by the third law of Kepler. From this conclusion, which is a necessary consequence of the peculiar conditions of the planetary system, it results that all the changes to which the orbits of the planets are subject in consequence of their reciprocal gravitation, are periodic, and that the system contains within itself no principle of destruction, but is calculated to endure for ever.

In 1780 Lagrange undertook a second time the subject of the moon's libration; and it is to the memoir which he now presented to the Berlin Academy that we must look for the complete and rigorous solution of this difficult problem, which had not been resolved before in a satisfactory manner, either on the footing of analysis or observation. In the same year he obtained the prize of the Academy of Sciences on the subject of the perturbations of comets. In 1781 he published, in the Berlin Memoirs, the first of a series of five papers on the secular and periodic inequalities of the planets, which together formed by far the most important work that had yet appeared on physical astronomy since the publication of the *Principia*. This series did not, properly speaking, contain any new discovery, but it embodied and brought into one view all the results and peculiar analytical methods which had appeared in his former memoirs, and contained the germs of all the happy ideas which he afterwards developed in the *Mécanique Analytique*.

On account of the brilliant discoveries and important labours which we have thus briefly noticed, Lagrange must be considered as one of the most successful of those illustrious men who have undertaken to perfect the theory of Newton, and pursue the principle of gravitation to its remotest consequences. But the value of his services to science is not limited to his discoveries in physical astronomy, great and numerous as these were. After Euler, he has contributed more than any other to increase the power and extend the applications of the calculus, and thereby to arm future inquirers with an instrument of greater efficiency, by means of which they may push their conquests into new and unexplored fields of discovery.

Laplace.

With the name of Lagrange is associated that of Laplace, their rival labours dividing the admiration of the scientific world during half a century. Like Newton and Lagrange, Laplace raised himself at an early age to the very highest rank in science. Before completing his 24th year, he had signalised himself by the important discovery of the invariability of the mean distances of the planets from the sun, on an hypothesis restricted, indeed, but which, as we have already mentioned, was afterwards generalised by Lagrange. About the same time he was admitted into the Academy of Sciences, and thenceforward devoted himself to the development of the laws which regulate the system of the world, and to the composition of a series of memoirs on the most important subjects connected with astronomy and analysis. His researches embraced the whole theory of gravitation; and he had the high honour of perfecting what had been left incomplete by his predecessors.

Among the numerous inequalities which affect the motion of the moon, one still remained which no philosopher as yet had been able to explain. This was the acceleration of the mean lunar motion, which had been first suspected by Halley, from a comparison of the ancient Babylonian observations, recorded by Hipparchus, with those of Albategni and the moderns. The existence of the acceleration had been confirmed by Dunthorne and Mayer, and its quantity assigned at 10″ in a century, but the cause of it remained doubtful. Lagrange demonstrated that it could not be occasioned by any peculiarity in the form of the earth; Bossut ascribed it to the resistance of the medium in which he supposed the moon to move; and Laplace himself at first explained it on the supposition that gravity is not transmitted from one body to another instantaneously, but successively, in the manner of sound or light. Having afterwards remarked, however, in the course of his researches on Jupiter's satellites, that the secular variation of the eccentricity of the orbit of Jupiter occasions a secular variation of the mean motions of the satellites, he hastened to transfer this result to the moon, and had the satisfaction to find that the acceleration observed by astronomers is occasioned by the secular variation of the eccentricity of the terrestrial orbit. This conclusion has, however, been partly invalidated by the recent researches of Adams of Cambridge.

Another discovery relative to the constitution of the planetary system, which does infinite honour to the sagacity of Laplace, is the cause of the secular inequalities indicated by ancient and modern observations in the mean motions of Jupiter and Saturn. On examining the differential equations of the motions of these planets, Laplace remarked, that as their mean motions are nearly commensurable (five times the mean motion of Saturn being nearly equal to twice that of Jupiter), those terms of which the arguments are five times the mean longitude of Saturn, minus twice that of Jupiter, may become very sensible by integration, although multiplied by the cubes and products of three dimensions of the eccentricities and inclinations of the orbits. The result of a laborious calculation confirmed his conjecture, and showed him that in the mean motion of Saturn there existed a great inequality, amounting at its maximum to 48′ 2″·3, and of which the period is 929 years; and that in the case of Jupiter there exists a corresponding inequality of nearly the same period, of which the maximum value is 19′ 46″, but which is affected by a contrary sign, that is to say, it diminishes while the first increases, and *vice versâ*. He also perceived that the magnitude of the co-efficients of these inequalities, and the duration of their periods, are not always the same, but participate in the secular variations of the elements of the orbit.

The theory of the figures of the planets, scarcely less interesting than that of their motions, was also greatly advanced by the researches of Laplace. He confirmed the results of Clairaut, Maclaurin, and D'Alembert, relative to the figure of the earth, and treated the question in a much more general way than had been done by those three great mathematicians. From two lunar inequalities depending on the non-sphericity of the earth, he determined the ellipticity of the meridian to be $\frac{1}{306}$ very nearly.

Newton, in the *Principia*, explained the cause of the phenomena of the tides, and laid the foundations of a theory which was prosecuted and extended by Daniel Bernouilli, Maclaurin, Euler, and D'Alembert; but as none of these geometers had taken into account the effects of the rotatory motion of the earth, the subject was in a great measure new when it was taken up by Laplace in 1774. Aided by D'Alembert's recent discovery of the calculus of partial differences, and by an improved theory of hydrodynamics, he succeeded in obtaining the differential equations of the motion of the fluids which surround the earth, having regard to all the forces by which these motions are produced or modified, and published them in the memoirs of the academy in 1775. By a careful examination of these equations, he was led to the curious remark, that the differences between the heights of two consecutive tides about the time of the solstices, as indicated by Newton's theory, are not owing, as Newton and his successors had supposed, to the inertia of the waters of the ocean, but depend on a totally different cause, namely, the law of the depth of the sea, and that it would disappear entirely if the sea were of a uniform and constant depth. He also arrived at the important conclusion, that the fluidity of the sea has no influence on the motions of the terrestrial axis, which are exactly the same as they would be if the sea formed a solid mass with the earth. The same analysis conducted him to the knowledge of the conditions necessary to ensure the permanent equilibrium of the waters of the ocean. He found that if the mean density of the earth exceeds that of the sea, the fluid, deranged by any causes whatever, from its state of equilibrium, will never depart from that state but by very small quantities. It follows from this, that, since the mean density of the earth is known to be about five times greater than that of the sea, the great changes which have taken place in the relative situation of the waters and dry land must be referred to other causes than the instability of the equilibrium of the ocean.

The chief steps in the progress of the study of tides since the time of Laplace have consisted in co-ordinating the results of observation, and analysing them into their partial phenomena, by the help of Newton's and Bernouilli's theory. This labour has been greatly advanced by Dr Whewell, and also by Sir John Lubbock. The former has constructed maps of "cotidal lines," which, indicating the relative time of high water in different parts of the globe, give us a graphic conception of the course and propagation of the tidal wave. The tides of the Eastern Pacific are but little known; but a vast wave advances northwards between Australia and Africa, diverted or retarded by the obstacles it meets with in the Indian Archipelago. Another (and to us the most important) branch sets from south to north up the vast canal of the Atlantic, where it is gradually complicated by local tides, having their origin in the wide expanse between Africa and the Gulf of Mexico. The two sets of waves sometimes reinforce, sometimes oppose one another; they are prolonged to the western shores of England and Norway, where the tidal impulse arrives twenty-four hours after it passed the Cape of Good Hope. It is propagated most rapidly at a distance from coasts, and is retarded in narrows and shallows. It sends offshoots into every bay and strait, always greatly retarded in point of time (apparently by friction), but often increased in elevation by concentration of the effect in a gradually narrowing channel, as we see in the exaggerated tides of the river Amazon, the Severn, and the Bay of Fundy. The same place may be the seat of several tides at once, which may increase or destroy one another; thus, a small tide is propagated through the Straits of Dover as far as the Dutch coast, where it only arrives simultaneously with the principal wave, which has made the entire tour of Great Britain.

As regards the progress of theory, Dr Thomas Young, one of the greatest philosophers of this century, next after Laplace grappled with the difficulties of this arduous subject. Employing mathematical methods of inferior power but greater directness, and taking into account causes of local action which Laplace had not ventured to include in his analysis, he gradually matured a theory adequate to represent many of the results of experience, of which Laplace gives no account. He distinguishes the results of the *forced* and *free* oscillations of the sea: the former resulting from the direct action of the sun and moon combined with the rotation of the earth, and whose periods of rise and fall are determined solely by those external causes; the free waves, on the contrary, derived from the former, are transmitted with velocities depending on the mechanism of the fluid itself, on its depth, and on the resistances arising from friction to which those motions are exposed. These all-important modifications of the dynamical theory of the tides were deduced by Young from the general theory of oscillations and resistances, and from the laws of fluids detected by Du Buat, and he applied them with no ordinary skill to the solution of the problems of tides in oceans, estuaries, and rivers. It is satisfactory to find that by an independent and very different method Airy subsequently arrived at substantially the same results as Young. Young.

Closely connected with the problem of the tides is that of the precession of the equinoxes, which also received similar improvements in passing through the hands of Laplace. He demonstrated, as has been mentioned, that the fluidity of the sea has no influence on the phenomena of precession and nutation. He considered some of the effects of the oblate figure of the earth which had not been attended to by D'Alembert, and showed that the annual variation of the precession causes a corresponding variation in the length of the tropical year, which at present is about 9 or 10 seconds shorter than it was in the time of Hipparchus. He proved that the secular inequalities of the motions of the earth and moon have no sensible effect in displacing the axis of the earth's rotation; and he determined the nutation of the lunar orbit corresponding to the nutation of the terrestrial equator.

Physical astronomy is also indebted to Laplace for a complete theory of the system of Jupiter's satellites, from which Delambre constructed a set of tables representing the motions of these bodies with all desirable accuracy. And when to these numerous and most important researches we add the mathematical theories of molecular attraction, and the propagation of sound, together with many great improvements in analysis,—and reflect, besides, that he is the author of the *Mécanique Céleste*, the *Système du Monde*, and the *Théorie des Probabilités*,—we shall not hesitate to rank him next to Newton among the greatest benefactors of the mathematical and physical sciences.

By the brilliant discoveries of Laplace, the analytical solution of the great problem of physical astronomy was completed. The principle of gravitation, which had been found by Newton to confine the moon and the planets to their respective orbits, was shown to occasion every apparent irregularity, however minute, in the motions of the planets and satellites; and those very irregularities which were at first brought forward as objections to the hypothesis have been ultimately found to afford the most triumphant proofs of its accuracy, and have placed the truth of the Newtonian law beyond the reach of all future cavil. Such is the state to which analysis has now attained, that the geometer embraces in his formulæ every circumstance which affects the motions or positions of the different bodies of the planetary system; and the conditions of that system being made known to him at any given instant of time, he can determine its conditions at any other instant in the past or future duration of the world. He ascends to remote ages to compare the results of his theories with the most ancient observations, he passes on to ages yet to come, and predicts changes which the lapse of centuries will hardly be sufficient to render sensible to the observer. But notwithstanding the comparative perfection to which the theory of astronomy has been brought, it is still far from having reached the limit beyond which further refinement becomes superfluous. The masses of the planets, and some other elements, remain to be determined with still greater precision, by a diligent comparison of the analytical formulæ with good observations; and the labours of the geometer may still be beneficially employed in giving greater simplicity to the calculus, or in extending its power over subjects which have hitherto eluded its grasp. The observation of periodic comets that complete their revolutions in comparatively short intervals of time, opens up an interesting field for speculation and research, and will doubtless be the means of throwing light on some curious and as yet very obscure points, respecting the appearances, motions, and physical constitution of those strange bodies.

In the other departments of astronomy, also, numerous questions still remain to be discussed, the solution of which will occupy and reward the future labours of astronomers, and in which much progress has been made during the present century, by means of the powerful instruments now employed at the great observatories of every civilised country, and the improved methods of analysis brought to bear upon the results of observation. The curious phenomena of double and multiple stars, some of which are found to form connected systems of bodies revolving about one another, or a common centre of motion,—the variable stars,—the proper motions of the stars,—the translation of the solar system in space,—the progressive condensation of nebulæ,—are subjects still in a great measure new; for it is only of late years that observers have begun to direct the requisite attention towards them, or indeed have been in possession of instruments of sufficient power and delicacy to observe and measure the minute changes which take place beyond the boundaries of our own system. The discoveries in astronomy during the present century have been so brilliant and numerous, and the progress in every department is so rapid, and involves so many details, that it would be impossible to give here a detailed account of that progress. Moreover, there is a reason for not attempting this, in the circumstance that we have brought the history of our subject as far as is possible without considering the work of men still living. For although some to whom the astronomy of the present day is indebted, and not a few who must always be regarded as among the leading astronomers of the century, have passed away, yet the consideration even of their work would necessarily introduce the discussion of the labours of those whose labours are still in progress. It seems on all accounts better, therefore, to content ourselves with the discussion of the various results obtained during recent years, without attempting the invidious task of apportioning to the several workers their relative positions.

Part II.—Theoretical Astronomy

Chapter I.—*Apparent Motion of the Star-sphere.*

When we look at the heavens on a clear night, we perceive a concave hemisphere on which are strewn multitudes of bright points. As we watch these hour after hour, we find that they are carried round precisely as though they were fixed on the interior surface of a spherical shell turning on a fixed axis. New groups are seen to rise above the eastern horizon, while those above the western horizon descend and finally disappear. Turning towards the south, we see that the groups of stars which pass above the horizon somewhat to the east of the south attain but a slight elevation when at their highest in the south, and then descending set as far to the west of the south point as they had risen to the east of it. Turning to the north, we see that there are groups of stars which remain visible the whole night, wheeling around a fixed point, and describing circles of greater or less magnitude according as they are at a greater or less distance from that point. Supposing our stand point to be in or near London, the point thus remaining fixed is due north, and about $51\frac{1}{2}°$ above the horizon,—therefore, about $38\frac{1}{2}°$ from the point directly overhead. If the heavens be observed night after night, similar phenomena are seen; and we recognise the uniformity of the motion of the (imaginary) star-sphere about its (imaginary) axis; for in any assigned interval, on any night in the year, the star-sphere turns by the same amount. It is soon found that the rate of turning is such that a complete rotation is effected in the course of about one day. But before many days have passed we find that this uniform turning motion does not correspond exactly to our common day. For though on several successive nights the stars may appear to be nearly in the same situation with respect to the horizon at any assigned hour, yet before long (or even in twenty-four hours if exact observation be made) it is found that the stars occupy the same position, *not* at the same hour on successive nights, but about four minutes earlier night after night. Thus, in the course of about fifteen days the star-sphere has gained one hour's rotation; in about thirty days, two hours' rotation, and so on: until in the course of a year the star-sphere has gained a complete rotation, and the stars have the same apparent position at any assigned hour of the night as they had when the observations were commenced.

Limiting our attention for the present to the stars,—though already, in speaking of the common day, we have in fact referred to the sun,—the idea suggested by the observed phenomena is that the apparent star-sphere revolves around the earth precisely as it seems to do, turning about an axis, with a perfectly uniform motion, completing one rotation in twenty-four hours, less about four minutes. The natural steps for determining whether this really is the case, are—first, a series of careful observations at one fixed station; and, secondly, a study of the effects produced by change of station.

For the former purpose we require to adopt certain fixed points or circles on the concave hemisphere visible above the horizon, in order that we may refer the apparent motions to these points or circles as unmoving standards.

Definitions. Let, then, NESW (fig. 1) represent the seemingly circular horizon line around the observer at O; N being the north point, S the south, E the east, and W the west, so that the lines SON and WOE are at right angles to each other. Let Z be the point immediately overhead; and let P, so placed on the quadrant ZPN that PN is an arc of $51\frac{1}{2}^\circ$, be the apparently fixed point on the heavens already described, so that POP′ is the imaginary axis about which the star-sphere appears to revolve. Then the points P and P′ are called the *poles* of the heavens. P is distinguished as the *visible pole* from P′, which is the *invisible pole*, for the station of the observer at O; PP′ is called the *polar axis*.

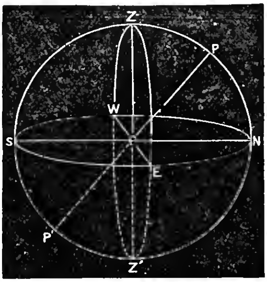

Fig. 1.

Poles.

Zenith. The point Z immediately overhead, or geometrically defined by the fact that OZ is perpendicular to the *plane of the horizon* NESW, is called the *zenith*; and Z′, the point in which ZO produced intersects the invisible hemisphere, is called the *nadir*. The line OZ is called the *vertical*. Any great circle of the sphere, whose plane passes through ZZ′, as the circle SZNZ′ or the circle EZWZ′, is called a *vertical circle*. The vertical circle SZPNZ′, which passes through the pole, is called the

Meridian. *meridian circle*, and its plane is called the *meridian*; because when the sun is on this circle it is true mid-day. The points N and S, in which the meridian circle meets the horizon, are called the *north* and *south points of the horizon*, the north point being distinguished from the south as being the extremity of the quadrant ZPN, on which is the visible pole P. (Reference is here made to the pole seen at the supposed station of the observer; that pole is the north pole of the heavens, and the north point of the horizon is N on the quadrant ZPN through the north pole.) The points N and S divide the horizon into halves, SEN, SWN—the former being the half along which the stars rise, the latter being the half along which they set. A vertical circle EZWZ′, having its plane at right angles to the meridian, is called the *prime vertical*, and intersects the horizon in two points, E and W, called respectively the *east* and *west points of the horizon*, the east being distinguished from the west as being on the part of the horizon crossed by rising stars, while the west is on the part crossed by setting stars.

Next, let EMWM′ (fig. 2) represent the path of a star which rises due east. Then EMWM is a circle whose plane passes through WOE, and is therefore a great circle of the sphere. The diameter WOE divides this circle into the semicircles EMW and WM′E, one above, the other below the horizon circle NESW,—that is to say, a star which rises in the east has one-half of its course above the horizon, and the other half below the horizon. Again, since the circle SZNZ′ has the points E and W for its poles, the arcs EM, MW, WM′, and M′E are quadrants,—that is to say, when a star rises in the east, one-fourth of a complete rotation brings it to the meridian, another fourth brings it to the west point, the next fourth part brings it again to the meridian at M′ below the horizon, and the remaining fourth part brings it to the east point again. The circle EMWM′ is called the *celestial equator*. It is the great circle having for its poles the points P and P′, which are the poles of the heavens. (It is sometimes, but perhaps not very correctly, called the *equinoctial*, because when the sun is on this circle, one-half of his course is above and the other below the horizon, and therefore day and night are equal; but, strictly speaking, the term equinoctial is applied to the geographical equator because there all the year round the nights are of equal length.) Equator

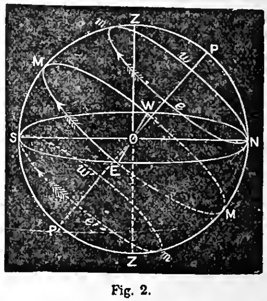

Fig. 2.

A star at N will clearly be carried by the diurnal motion round the circle N*emw* to N again, not passing below the horizon; and any star on the segment of the sphere PN*emw* will be always above the horizon. Hence the circle of N*emw* is called the *circle of perpetual apparition*, as limiting the region of the stars which never set. Such stars are called *circumpolar* stars. There is evidently an equal opposite region, P′S*w′m′e′*, around the invisible pole, the stars in which are never seen above the plane of the horizon. It is clear that any circle parallel to the equator, between the circle of perpetual apparition and the equator, has more than its half above the horizon, and so much the more as it lies nearer to the circle of perpetual apparition; that is to say, stars rising in the quadrant EN are above the horizon for more than half the time of a complete rotation of the star-sphere, and the nearer they rise to N the longer they continue above the horizon. In like manner stars rising in the quadrant ES are above the horizon for less than half the time of a complete rotation, and the nearer they rise to S the shorter is the time during which they are above the horizon.

Let us suppose the sphere of fig. 2 so placed (fig. 3) that the horizon plane appears as a straight line SON, O being the place where the east and west points coalesce. Thus the equator appears as the straight line MOM′ at right angles to the polar axis POP′; the circles *m*N, S*m′* of fig. 2 become the straight lines *m*N, S*m′* parallel to MM′ in fig. 3. And parallel circles intermediate between these two and the equator appear as the parallel straight lines ACB, A′C′B′; while parallel circles outside the circles *m*N and S*m′* appear as the parallel straight lines *acb* and *a′c′b′* All these parallels being at right angles to PP′ are bisected by PP′. Now, if we consider that the straight line AHB represents a circle seen edgewise, we perceive that AH represents two equal arcs of the circumference of this circle, one arc being that on which a star moving along that circle by the diurnal motion is carried from the horizon to the meridian at A, and the other being the arc on which the star is carried from A to the horizon again. In like manner H′A′ represents two equal arcs of a star's diurnal course,—that is to say, the arcs of a star's visible path on the two sides of the meridian are equal to one another. Similarly the meridian divides the invisible part of a star's course into equal parts. In the case of a star within the circle of perpetual apparition we perceive that *acb* represents two semicircles of such a star's diurnal circuit, one-half lying on the east of the meridian, the other lying on the west; in this case, then, as in the former, the meridian separates the ascending from the descending paths, which are equal, but the ascent is from a point on the meridian below the pole, *not* from the horizon, and the descent is to the same point of the subpolar meridian. It will be noticed that a in fig. 3 lies to the north of the zenith Z; but it is also clear from the figure that some of the circumpolar stars cross the meridional arc SMP to the south of the zenith.

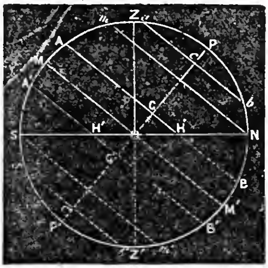

Fig. 3.

We see from fig. 3 that a star is always at its highest above the horizon when on the part PZS of the meridional circle. A star is said to *culminate*, or to reach its *culmination*, when on the meridian. The arc of the meridian intercepted between the star and the south point is called the star's *meridian altitude;* and the arc of the meridian between the star and the zenith is called the star's *zenith distance*, or more correctly, the *meridional zenith distance*. The arc-distance of a star from the equator is called its *declination*, and is northern or southern according as the star is in the northern or southern of the two hemispheres into which the equator divides the celestial sphere. The arc-distance of a star from the north pole is called the *north polar distance*, the supplement of this arc (the arc-distance from the south pole) being called the south polar distance. It is evident that the north polar distance of a star having northern declination is complementary to the declination,—that is, N.P.D. = 90° − N. Dec. But when a star has southern declination N.P.D. = 90° + S. Dec. When we know the declination or polar distance of a star, we know where it will culminate. For we see from fig. 3 that

$$\text{Arc SA} = \text{SM} + \text{MA}.$$

In other words, the altitude of a star culminating at A is equal to the altitude of the equator on the meridian added to the northern declination of the star. (The arc SM is obviously equal to ZP, the zenith distance of the pole, or the complement of the pole's altitude above the horizon.) Again

$$\text{Arc SA} = \text{SM} - \text{MA}',$$

or the altitude of a star culminating at A′ is equal to the altitude of the equator on the meridian diminished by the southern declination. These relations hold so long as the star culminates on the arc SZ. For a star culminating at a we have still

$$\text{S}a = \text{MS} + \text{M}a.$$

But the altitude of the star, being in this case measured from the north point N, is the supplement of the arc obtained by thus adding the north declination to the meridional altitude of the equator.

We see then that the declination of a star (or its north polar distance) determines the altitude of its culminating point. To determine the time at which the star culminates it is necessary that another co-ordinate should be known.

As we measure the declination from the equator, or in other words, determine the altitude of culmination by a reference to the equator, it is manifestly convenient to measure the time of a star's culmination by referring it to the time of culmination of some selected point on the equator. This is the course adopted by astronomers. The point selected for the purpose is one of the two points in which a great circle on the celestial sphere, called the ecliptic, and presently to be more particularly described, cuts the equator. This point is called the first point of Aries, and is indicated by the sign ♈. At present it is only necessary to note that this point is in reality affected by a slow motion on the star-sphere, due to the fact that the axis on which the star-sphere apparently turns undergoes a slow change of position within the star-sphere itself, so that the equator is not really a fixed circle on the heavens. But for the purpose we have at present in view this slow change may be neglected; and we assume that the observer on earth has the equator as a fixed circle from which to measure the declination of stars, and that he also has a fixed point on the equator by which to time the culmination of each star. Knowing the declination of a star, he knows at what altitude it will culminate as viewed from the fixed station at which thus far we have supposed him to be placed. Let him now note the exact moment at which the first point of Aries culminates, and let him observe the precise interval in time between that moment and the moment when a star of known declination culminates; this interval is constant, and thereafter he will always know not only at what altitude that star will culminate, but at what time after the culmination of the point ♈. The interval in time between the culmination of ♈ and the culmination of a given star is called the *right ascension* of the star. It may be measured, indeed, as an arc, viz., as the arc on the equator intercepted between ♈ and that point in which a meridian circle through the star intersects the equator, the arc being measured in the direction opposite to that in which the star-sphere rotates. But the right ascension is more conveniently and now almost always measured in time.

The time measurement employed is the rotation of the star-sphere itself. The interval in time between the successive culminations of ♈ is called a *sidereal day*. It is divided into 24 hours (numbered 0, 1, 2, 3 . . . to 24), each hour into 60 minutes, each minute into 60 seconds. If we have a clock showing 24 hours, and so rated as always to show 0 hour 0 min. 0 sec., when ♈ is at its culmination, that clock will always show true sidereal time. Such a clock would gain nearly 4 min. a day as compared with an ordinary clock; but we need not at present dwell upon this point. Now the right ascension (or, as it is written, the R.A.) is indicated in sidereal time, and therefore corresponds to the time shown by the sidereal clock when that star is culminating. Thus, if a star's right ascension is 3 h. 2 m. 6 s., then when the sidereal clock shows time 3 h. 2 m. 6 s., that star is culminating. Whether it be day or night the astronomer knows this certainly, that is, if his sidereal clock is trustworthy.

It will be manifest that an observer at a fixed station as we have thus far supposed our observer to be, requires to have the means of determining—(1) the moment at which a star culminates (or is on the meridian), and (2) the star's altitude when at its culmination. We have seen how the movement of the star-sphere determines the *cardinal points* of the horizon. Suppose now a telescope or pointer, so set as to turn upon a horizontal axis lying exactly east and west, as in fig. 4. We see that when the telescope is rotated on this axis, the line of sight, *es*, or the optical axis of the telescope, sweeps round in the plane of the meridian. It can be directed due south towards S, or to Æ (the culminating point of the celestial equator), or to *s*, a star on the meridian, or to the zenith Z, or to the pole P, or to the north point N,—in fine, to any point on the celestial meridian.

Transit instrument.

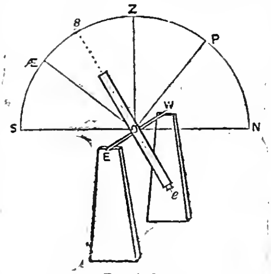

FIG. 4.—Transit Instrument.

Now, if any contrivance be adopted to enable the observer to note the exact moment of sidereal time when a star crosses the middle of the field of view of such a telescope, then the right ascension of that star is known at once. If also the angle ZO*s* can be determined, we learn the star's zenith distance. This added to ZP, the zenith distance of the pole, is the star's north polar distance, PZ*s*; and in this instance the complement of the zenith distance is the north declination. Such an instrument, if devised simply or mainly for noting the moment of culmination, is called a *transit instrument.* If arranged with circles so that angles—as the zenith distance Z*s*—can be determined, the instrument is called a *transit circle.* An arrangement, now little used, in which a meridional circle bearing a telescope works against a fixed plane surface or wall (necessarily standing in a north-and-south position) is called a *mural circle.* At present, however, we need not discuss these varieties of construction. The point to be specially noted in this plan is that, from observations of the star-sphere, we determine the cardinal points; and then the position of any star in the heavens can be determined by an instrument contrived so as to swing in the plane of the meridian. This done, a clock, carefully rated to show sidereal time, enables the astronomer at a fixed station to turn his transit instrument to the point of culmination of a star at the exact time when the star will culminate, and at the true place of such culmination.

CHAPTER II.—*The Earth shown to be a Globe within the Star-Sphere.*

But now let us suppose our observer to travel in a north-and-south direction, in order to determine what change, if any, will be produced by such voyages. The first effect noticed is that the pole of the heavens rises higher and higher above the northern horizon, as he travels farther and farther north, whereas the pole sinks lower and lower down towards the northern horizon the farther the observer travels towards the south. Close observation shows that the change of the pole's elevation is either exactly proportional to the observer's change of place in a north-and-south direction, or so nearly so that any discrepancy will require the closest and most exact scrutiny. The observer also notices that the stars retain their relative positions absolutely unaltered, but that new stars are seen in the south when he travels southward. This shows that the star-sphere is either truly a spherical enclosure,—all the stars lying at the same distance,—or else that the distances of the stars are so enormous that the displacement of the observer on the earth, even by several hundred miles, is as nothing by comparison. The uniform change in the pole's elevation cannot be explained, however, by merely supposing the stars very far away compared with terrestrial distances. For let us suppose that A, B, C, D (fig. 5) represent four equidistant stations along a *straight* north-and-south line SN, and that AP is the direction in which the polar axis seems to lie, as seen from the station A, then from D it is seen at a greater elevation, or as in direction DP. Now, if we suppose P to be the actual pole of the heavens, then BP and CP should represent the polar axis as observed at B and C; but the angles PAN, PBN, PCN, PDN, do not increase uniformly, for this would imply that the angles APB, BPC, and CPD are equal, which we know from geometry not to be the case. Moreover, the star-sphere cannot rotate uniformly about two different axes, as PA and PD.

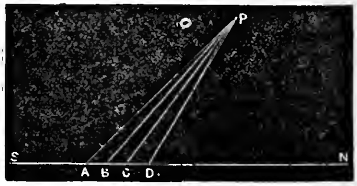

Fig. 5.

It is manifest that we can only explain the observed facts by assuming that the course pursued by the supposed observer is not a straight line as SN (fig. 5), but curved, and that it is curved uniformly, since the polar elevation changes uniformly when the observer travels at a uniform rate. It follows, therefore, that the path of the observer must be part of a circular arc such as d a g in fig. 6. Here suppose a the first position of the observer, and that when

Earth's surface curved north and south.

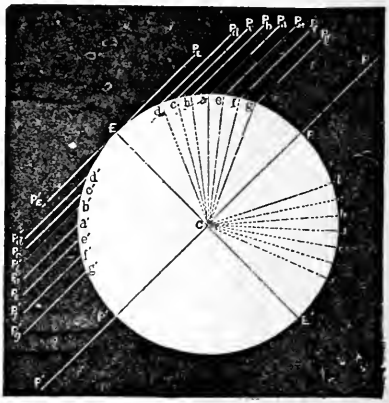

FIG. 6.—Diagram to show Curvature of Earth.

he travels southwards he passes over the equal arcs a b, b c, c d, &c., while his northward course from a carries him over the equal arcs a e, e f, f g. From a let the north pole of the heavens be seen in the direction aP$_a$, and for convenience, instead of drawing the south-and-north horizon line at a (which would be a tangent to the arc d g at a, and would be confused with other tangents required to be drawn from b, c, d, &c.), let us draw a vertical line downwards from a to C, that is, towards the *nadir*, and let us draw C*a* at right angles to aC, meeting the circle EaE′, of which dg is an arc, in *a*. Through C, the centre of this circle, draw PCP′ parallel to aP_a. Then we suppose throughout that the pole of the celestial sphere is so far off compared with the dimensions of the circle EaE′, that the apparent direction of the polar axis at all points of the arc d g is the same, and therefore parallel to CP. Thus the polar axis at b is represented by the line bP_b, at c by the line cP_c, and so on. Draw the vertical lines bC, cC, dC, &c., and at right angles to them, through C, draw C*b*, C*c*, C*d*, &c.; then clearly the angular elevation of the pole at a, or the angle $P_a ac$, is equal to the angle PC*a*; at b the elevation of the pole, or the angle $P_b ba$, is equal to the angle PC*b*; at c to PC*c*, and at d to PC*d*. But these angles PC*a*, PC*b*, PC*c*, PC*d*, diminish uniformly. In other words, to an observer travelling uniformly along an arc a b c d towards the south, the angular elevation of the pole would diminish uniformly, as it is observed to do, *if* (1) the arc d a is circular, and (2) the pole of the heavens so far from the observer that lines drawn to it are appreciably parallel. Similarly the uniform increase of the polar elevation, to an observer travelling northwards along the arc a g, is explained, since the elevation of the pole, as he passes to the stations e, f, and g, changes through the values PC*e*, PC*f*, PC*g*, increasing therefore uniformly.

Continuing this voyage beyond ad, southwards, the observer finds the pole continues to sink, until at length when he has arrived at a station E, the north pole of the heavens is on the horizon due north, or in direction EP_E. All the phenomena of celestial rotation continue unchanged, except that towards the south many new stars have come into view. Moreover, the south pole of the heavens has now risen to the horizon, and lies due south, or in direction EP'_E. If the observer were now to retrace his course, he would, of course, find the north pole of the heavens rising uniformly again. But if instead of this he continue his journey southwards, he finds the south pole of the heavens rising uniformly. As he travels onwards to the successive stations d′, c′, b′, a′, &c., so placed that Ed′ = Ed, Ec′ = Ec, &c., the phenomena presented may be described exactly as for the northern stations d, c, b, a, &c., respectively, except that for northern must be written southern, and for southern northern, throughout.

The difference in the position of observers on the northern and southern sides of E, fig. 6, may be conveniently illustrated as in fig. 7, where G represents the place of an observer near Greenwich, and C the place of an observer near Cape Town, but due south of the former, and HZ*h*, H′Z′*h*′, are supposed to represent the apparent hemispherical dome of the heavens above and around these respective observers. (These hemispherical domes should, of course, be very much larger in proportion, each being here represented with a radius of about 3500 miles, whereas the nearest of the celestial bodies, our moon, is nearly 240,000 from us.) G*p* represents the apparent direction of the northern celestial pole as seen from Greenwich, raised about $51\frac{1}{2}°$ above the north point of the horizon at *h*, and G*e* is the direction of the southern or culminating point of the celestial equator, about $38\frac{1}{2}°$ above the south point H of the Greenwich horizon. (The east and west points of the horizon-circle are projected at the point G.) At C, C*p*′ is the direction of the southern celestial pole, about $34\frac{1}{2}°$ above the southern horizon at H′; C*e*′ is the direction of the culminating or north point of the celestial equator, about $55\frac{1}{2}°$ above the northern horizon at *h*′.

Measurement of the earth. We see that journeys taken in a north-and-south direction lead to apparent changes of the dome of the heavens, only explicable on the assumption that the path traversed is a circular arc, or nearly so. It is clear also that the radius of this circular arc is determinable if the observer notes how much the elevation of the pole is

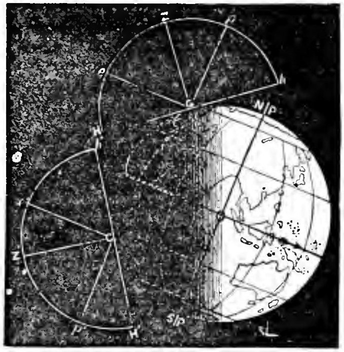

FIG. 7.—Domes of Heavens near Greenwich and near Cape Town.

changed for any given distance traversed by him in a north-and-south direction. Suppose, for instance, that in travelling from a to b (fig. 6) he finds the elevation of the pole diminished by 7°, and that he has travelled about 480 miles, then (as already shown) he knows that ab = *ab* = change in polar elevation = an arc of 7° of the circumference of the circle along which he is travelling. Hence the whole circumference $= \frac{360}{7} \times 480$ miles = 24,686 miles; whence the diameter of the circle = (roughly) $24{,}686 \times \frac{7}{22} = 7855$ miles. This is not the true diameter of the earth's globe, being supposed to be the result of only a rough observation; but the method serves sufficiently to show how in very early times astronomers obtained a measure of the earth. For from whatever station the observer starts on north-and-south journeys, the same uniform elevation or depression of the visible pole as he travels towards or from it is observed; and the inference, therefore, is that the earth is a globe, since all the lines drawn on it in a north-and-south direction are circular arcs of equal radius. The points corresponding to E, where the poles are both on the horizon, mark the place of the *terrestrial equator*; and the points on the earth, P and P′ (which have never yet been reached), where the north and south celestial poles are respectively vertical, are the *terrestrial* or *geographical poles*.

Earth's surface curved east and west. Thus far we have considered only journeys made along a north-and-south course. Journeys pursued due east or due west, that is, always towards the point of the horizon which is 90° to the right or to the left of the north point, show equally that the observer is travelling on the surface of a globe, though they produce no apparent change either in the elevation of the pole or in the position of the points at which known stars rise, culminate, and set. We have seen that the observer who remains always at one station can determine the absolute time when any given star will culminate. Let us suppose that when journeying eastward or westward he can carry with him his sidereal time-measurer, and that this continues throughout to show the true sidereal time of his original station. Then if he is travelling eastward he will find that any given star, instead of culminating at the time noted for that star as observed at his original station, will culminate earlier. The right ascension of the star will remain unchanged, for this is the difference between its time of culmination and the time when the point ♈ culminates. But instead of ♈ culminating when the clock points to 0 h. 0 m. 0 s. of sidereal time, it will culminate *before* the clock so points; and each star will culminate as much before *its* sidereal time, that is, before the sidereal time corresponding to its right ascension. On the contrary, if the observer travels westwards from his original station, he finds that each star culminates later. Moreover, the observer finds that the amount of change in point of time corresponds to the distance he travels. Suppose a, fig. 8, to be his original station, and let aa' be a small circle of a globe, having P and P′, as before determined (see fig. 6), for poles. Then the observer finds that the change in the time of a star's culmination corresponds exactly to the length of arc traversed by him round the circle aa', on the assumption that a complete circumference of this circle corresponds to 24 hours of sidereal time. Thus, if a is at Greenwich, the polar elevation is $51\frac{1}{2}°$, and, therefore, Ea (from what has been already shown in explaining fig. 6), is an arc of $51\frac{1}{2}°$; ao, the radius of aa', = EO sin. $51\frac{1}{2}°$, and the observer finds that T, the change of time in the culmination of ♈, or any given star, for a given easterly or westerly distance d traversed from Greenwich, is such that

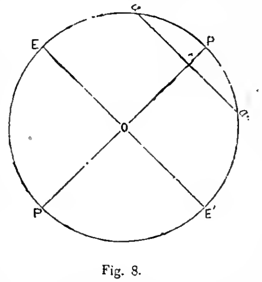

Fig. 8.

$$T : \text{a sidereal day} :: d : 2\pi . \text{EO} . \sin. 51\tfrac{1}{2}°$$

This corresponds with the result of the former series of observations in showing that the earth is a globe, suspended, as it were, within the star-sphere; and that either the star-sphere turns uniformly around this terrestrial globe from east to west once in 24 sidereal hours, or else the terrestrial globe turns uniformly round the axis PP′ (fig. 6) once in 24 sidereal hours from west to east.

Chapter III.—*Of the Apparent Motions of the Sun.*

The earth has now been shown to be a globe within the star-sphere, and whether the earth rotates within the star-sphere, or the star-sphere rotates round the earth, or both the earth and the star-sphere rotate, it is known that, *relatively to the earth*, the star-sphere rotates from east to west once in 24 sidereal hours. This rotation, whether apparent or real, takes place without any appreciable change in the relative position of the fixed stars. And the law of rotation having once been ascertained, it follows that the time of culmination of any star, and the position of the star at the time, are known, insomuch that a telescope or pointer can be directed to the place of the star at the moment of culmination with perfect exactness. Moreover, a star can be followed by an instrument properly devised, in such sort that a pointer shall continue directed upon the star all through the 24 sidereal hours. Suppose, for example, that

Equatorial instrument.

PP′ (fig. 9) is a rod turning on pivots P and P′ so placed that the axis of the rod points to the pole of the heavens; then if TT′ be a telescope so attached to an axis in or on PP′ (as at O) that it can be turned in any angle to PP′; then if this telescope be placed so that $e\,s$, its optical axis, is directed towards a star (in which case, necessarily, the angle POs will be equal to the star's north polar distance), it is clear that by rotating the axis PP′ uniformly once in 24 sidereal hours, and in the direction corresponding to the rotation of the heavens, the optical axis es will continue to be directed towards the star throughout the whole of those 24 hours, even when the star is below the horizon. If a star's north polar distance be known, a telescope thus mounted can be placed so that POs is the proper angle, without seeing the star. If, further, we know the star's right ascension, and also the true sidereal time, we can not only set the telescope so that POs shall be the proper angle, but can rotate the axis PP′ in such sort that the telescope shall be pointed directly towards the star. Suppose, for example, that the star's N.P.D. = 75°, and the R.A. = 1 hour 26 min. (or $21\frac{1}{2}°$), (in other words, the star is close to η of the constellation Pisces); and let the time indicated by the sidereal clock be 3 hours 10 min. Then set TT′ (fig. 9) so that the angle POs = 75°, turn the axle PP′ so that TT′ or es lies in the meridian,—in other words, let the telescope be directed due south, only with an elevation of $53\frac{1}{2}°$, which is the supplement of 75° + the polar elevation at Greenwich, where the observation is made. Then, since the sidereal time is 3 hours 10 min., we know that the point ♈ was on the meridian 3 hours 10 min. before the moment of observation; and since the star's R.A. = 1 hour 26 min., we know that the star was on the meridian 1 hour 26 min. after ♈; hence the star was on the meridian 1 hour 44 min. (3 hours 10 min. − 1 hour 26 min.) before the moment of observation. We have then only to rotate the axis PP′ so as to follow the rotation of the star-sphere through an angle of 26° (the angle corresponding to 1 hour 44 min., since 360° corresponds to 24 hours) to have the telescope directed upon the star. And as we can thus direct a telescope, mounted as shown in fig. 9, towards a star at any hour (even when a star is below the horizon, in which case, of course, the telescope will be directed downwards), so conversely, it is clear that when the telescope is directed in any manner we can tell towards what point of the star-sphere the tube is turned. Thus, if the time shown by the sidereal clock is 3 hours 10 min., and the telescope be in such a position that, in order to bring it to the meridian, it would have to be turned round the polar axis backwards through an arc of 26°, corresponding to the rotation of the heavens in 1 hour 44 min., then we know that it is directed to a point in the star-sphere whose right ascension is 3 hours 10 min. − 1 hour 44 min., or 1 hour 26 min. If, further, we note that the angle POs is one of 75°, we know that the north polar distance of the point towards which the telescope is directed is 75°. The point, therefore, is known, and is close to the star η Piscium.

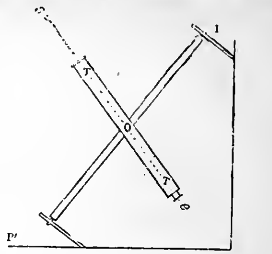

Fig. 9.—Equatorial Instrument.

We perceive, then, that if any celestial object is visible, whether by day or night, then by simply directing towards it such a telescope as is shown in fig. 9, we can ascertain in what part of the stellar heavens that celestial object lies. And if the object is moving upon the stellar heavens,—or, in other words, if it is other than one of these fixed stars with which we have hitherto been dealing,—then by turning a telescope towards it from time to time we can determine its apparent path among the stars. So that in the case of the sun, which is never seen in company with the stars simply because his light, by illuminating our air, veils the stars from view, we can nevertheless ascertain exactly along what path on the star-sphere he seems to move, at what rate, and whether the rate is uniform or variable.

Refraction. But before we examine the results of observations carried out for this purpose, it will be well to consider a circumstance affecting observations made in this manner. We refer to the refractive action of the earth's atmosphere, by which the apparent positions of the celestial bodies are to some degree affected. This is the proper place to mention the effects of refraction, because there can be little doubt that it was during observations of the sun that the refractive action of the atmosphere was first discovered. However, in explaining this action reference will be made to the stars as heretofore, in order that the inquiry into the sun's apparent motions may be referred solely to the sphere of the fixed stars.

By a well-known optical law, a ray of light in passing obliquely from one medium to another of greater density is refracted or bent towards the normal to their common surface. We may regard our atmosphere as composed of an infinity of concentric spherical shells, whose densities increase the nearer they are to the earth's surface. When a ray of light from a star enters the atmosphere, therefore, it is inflected towards the earth, and the inflection is increased by every successive stratum of the atmosphere through which the light passes. In fig. 10, let AA′, BB′, CC′,

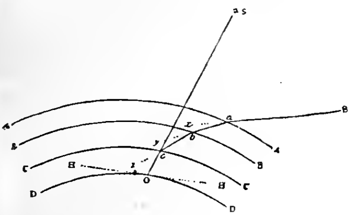

Fig. 10.

represent the boundaries of successive strata, supposed for convenience to have a finite thickness. A ray of light from S, reaching the highest stratum at a, leaves its original direction Sax, and travels in the direction aby; reaching the next stratum at b it is further bent, viz., from direction aby to the direction bz; and at c it is deflected in the direction cO. In its progress from a to O, it has therefore successively moved in the direction of the sides of the polygon abcO; and to the spectator at O, the star from which it proceeded, instead of appearing in its true place at S, will appear to be at S, or in the last direction of the visual ray. Now if AA is the most elevated stratum of the atmosphere into which the ray enters in the direction Sa, it is clear that the whole effect is produced by the atmospherical strata situated below AA, and that the length of Sa is perfectly indifferent; hence the refraction is entirely independent of the distance of the stars, provided they are beyond the limits of the earth's atmosphere.

The decrease of the density of the atmosphere, from the surface of the earth upwards, follows the law of continuity, or takes place by insensible degrees; so that the luminous ray, in traversing the atmosphere, enters at every instant into a denser medium, and is therefore continually brought nearer and nearer to the vertical direction. Hence the true path of the ray is curvilinear, and concave towards the earth, as represented in fig. 11. This is equivalent to the supposition that the thickness of the different concentric strata of uniform density is infinitely small, and that the light, as it successively penetrates each, deviates from its former path by an infinitely small angle, which may be considered as the differential of the refraction, the total amount of which will therefore be obtained by integration. The direction of the ray, when it reaches the eye of the observer, is the tangent to the last portion of its curvilinear path; and the apparent zenith distance of the star will be ZOS, while the real zenith distance is ZOS. The difference of these two angles, namely S′OS, is what is denominated the *Astronomical Refraction*. It is evident that the whole path of the ray is confined to the vertical plane in which the star and the eye of the observer are situated; for the earth and its atmosphere being very nearly spherical, that plane will divide the strata symmetrically; there will, therefore, be no displacement in a lateral direction, *i.e.*, no refraction out of the vertical plane. When the observed star is due north or south, the vertical plane is the plane of the meridian; hence, in meridional observations, the whole of the refraction takes place in declination, while the right ascension remains unaltered.

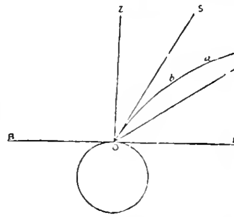

Fig. 11

It is evident that the amount of the refraction is greater in proportion as the observed star is nearer to the horizon; for in this case the luminous rays strike the tangent planes of the atmospherical strata more obliquely, and have besides to traverse a greater extent of atmosphere before they arrive at the eye of the observer. On determining by experiment the refraction at every altitude from zero to 90°, tables of *Refraction* may be constructed, which will furnish the means of discovering the law of its diminution; but as such a process would be exceedingly tedious, and likewise apt to lead to erroneous results on account of the inevitable errors of observation, it is found more convenient to assume some hypothesis for a basis of calculation, and to verify the results which it leads to by comparing them with observation. In regard to media which may be said to be permanent,—such, for instance, as water and glass,—the determination of the refraction is not attended with great difficulty; but the circumstances are greatly altered when we come to make experiments on the atmosphere. In this case the difficulty arises from the incessant changes which the atmosphere is undergoing relatively to its refractive power,—changes which it is impossible for the observer fully to appreciate, inasmuch as he can only determine its physical state within a short distance of the earth, while that of the upper strata remains wholly unknown to him. The refractive power of the atmosphere is affected by its density and temperature. The effects of the humidity are insensible; for the most accurate experiments seem to prove that the watery vapours diminish the density of the air in the same ratio as their refractive power is greater. It is therefore only necessary, even in delicate experiments, to have regard to the state of the barometer and thermometer at the time the observation is made. At a medium density, and at the temperature of melting ice, it was found by Biot and Arago, from a great number of exact experiments, that at any altitude between 10° and the zenith the refraction is very nearly represented by the formula $r = 60''\cdot 6$ tan. $(Z - 3\cdot 25 \times r)$, in which r is the refraction corresponding to a given zenith distance Z. With the exception of the numerical coefficients, this formula was first given by Bradley; but whether it was deduced from theory by that astronomer, or was only empirical, is uncertain. Bradley's formula was $r = 57'' \tan. (Z - 3 \times r)$. When the direction of the luminous rays makes a smaller angle than 10° with the horizon, it becomes indispensable to take into account, in the calculation of the refraction, the law of the variation of the density of the atmosphere at different altitudes,—a law which is subject to incessant variation, from the operation of winds and other causes which agitate the atmosphere, as well as the decrease of temperature in the superior regions. For this reason all astronomical observations which have not refraction directly for their object, or which are not by their nāturo independent of its influence, are made at an elevation exceeding 10°. For lower altitudes it is to be feared that no theory will ever be found sufficiently exact to entitle the observations to much confidence.

[It may be explained here in passing that the refraction of the rays of light in traversing the earth's atmosphere is the cause of *Twilight*, which sensibly lengthens the duration of the day, and prevents a sudden transition from light to darkness on the disappearance of the sun. When the sun is more than 33′ below the horizon, the refraction is not powerful enough to bring his rays sufficiently near the earth to reach our eyes; they pass over our heads, and are irregularly reflected by the molecules of the atmosphere. By this means a portion of the celestial vault is enlightened, while the sun is invisible. This illumination of the upper regions is called the twilight. It commences as soon as objects can be distinguished before sunrise, and terminates when they cease to be visible after the sun has set. The time, however, at which the twilight commences and terminates cannot be assigned with any degree of precision. It is generally supposed to be limited by the depression of the sun 18° below the horizon. Lacaille found the limit in the torrid zone to be between 16° and 17°. According to Lemonnier, it varies in France between 17° and 21°. The duration of the twilight will evidently be longer or shorter according as the inclination of the sun's motion to the horizon is more or less oblique.

Enlargement of sun and moon near horizon.

The apparent enlargement of the sun and moon near the horizon is an optical illusion, connected in some measure with the atmosphere, of which various explanations have been given since the time of Ptolemy. According to the ordinary laws of vision, the celestial bodies, particularly the moon, which is nearest to the earth, ought to appear largest in the meridian, because their distance is then less than when they are near the horizon; yet daily experience proves that the contrary takes place. To an observer placed at E (fig. 12), the visual angle subtended by the moon, in the horizon at M, is somewhat less than that under which she appears in the zenith at O; and this fact, a consequence indeed of her circular motion, is proved by accurate measurement of her diameters in those circumstances by the micrometer. The mean apparent diameter of the moon, at her greatest height, is 31′ in round numbers, but in the horizon she seems to the eye two or three times larger. The commonly received explanation of this phenomenon was first given by Descartes, and after him by Dr Wallis, James Gregory, Malebranche, Huyghens, and others, and may be stated as follows:—The opinion which we form of the magnitude of a distant body does not depend exclusively on the visual angle under which it appears, but also on its distance; and we judge of the distance by a comparison with other bodies. When the moon is near the zenith there is no interposing object with which we can compare her, the matter of the atmosphere being scarcely visible. Deceived by the absence of intermediate objects, we suppose her to be very near. On the other hand, we are used to observe a large extent of land lying between us and objects near the horizon, at the extremity of which the sky begins to appear; we therefore suppose the sky, with all the objects which are visible in it, to be at a great distance. The illusion is also greatly aided by the comparative feebleness of the light of the moon in the horizon, which renders us in a manner sensible of the interposition of the atmosphere. Hence the moon, though seen under nearly the same angle, alternately appears very large and very small. Desaguliers illustrated the doctrine of the horizontal moon by the supposition of our imagining the visible heavens to be only a small portion of a spherical surface, as *mnop* (fig. 12), in which case the moon, at different altitudes, will appear to be at different distances, and will therefore seem to vary in magnitude, as at *m*, *n*, *o*.]

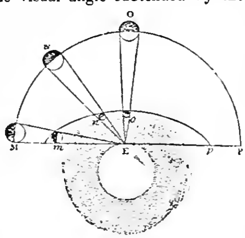

Fig. 12.

Correction being made for refraction, the true position of the sun on the star-sphere can be ascertained day after day; and thus his apparent motions, as we have said, can be determined.

Apparent motion of the sun. The year.

The result of such observations is to show that in a period of about 365 days the sun traverses a great circle of the star-sphere inclined to the equator. This period is called a *year*, and is familiar to all as the period in which the sun's varying positions, alternately north and south of the equator, bring about the circuit of the seasons. For we have already seen that a star to the north of the equator is above the horizon more than half the sidereal day, and at its meridian culmination has an altitude exceeding that of the south point of the equator. When the sun is north of the equator he has a daily arc like that of a star similarly placed, so that day lasts longer than night, and at mid-day the sun pours his heat more directly on the earth than if he were on the equator. In like manner it is shown that, when the sun is south of the equator, night lasts longer than day, and the sun at mid-day has a smaller altitude than if he were on the equator. The result of constant experience shows, that the sun's declination reaches its maximum on the south side of the equator about the 22d of December, when it amounts to 23°·465. From this time it gradually diminishes till about the 21st of March, when the sun reaches the plane of the equator. At this time the days and nights are of equal length all over the earth, and the instant of time at which the sun's centre is in the equatorial plane is called the instant of the equinox. The sun then passes to the northern side of the equator, and his declination or meridional altitude continues to increase till about the 22d of June, when he becomes stationary, and then again shapes his course towards the equator. His maximum declination on the north side of the equator is exactly equal to that on the south, amounting to 23°·465. The sun now continues to approach the equator till about the 24th of September, when he again reaches that plane, and a second equinox succeeds. Continuing still to move in the same direction, he declines from the equator southward, till he reaches his former limit about the 22d of December; and so on continually.

Tropics.

The two small circles of the sphere, parallel to the equator, which pass through the two points where the declination is greatest, are called the *Solstices* or the *Tropics*; that on the northern hemisphere is called the *Tropic of Cancer*, and the other is called the *Tropic of Capricorn*.

These two parallels, which mark the extreme limits of the sun's declination, are, as has just been stated, equally distant from the equator, with regard to which the variations of declination on either side are perfectly symmetrical and uniform.

The observations of the sun's right ascensions and meridional altitudes, which have been made daily during so great a number of years, and under so many different meridians, furnish complete proof that the projection of the sun's orbit is a great circle of the celestial sphere, and that the orbit itself is wholly confined to the same plane.

Ecliptic. The great circle which the sun describes in virtue of his proper motion is called the *Ecliptic.* It has received this name from the circumstance that the moon, during eclipses, is either in the same plane or very near it. These phenomena can, in fact, only happen when the sun, earth, and moon are nearly in the same straight line, and, consequently, when the moon is in the same plane with the earth and the sun. The angle formed by the planes of the ecliptic and equator, which is measured by the arc of a circle of declination intercepted between the equator and **Definitions** tropic, is called the *Obliquity of the Ecliptic.* The two points in which the equator and ecliptic intersect each other are called the *Equinoctial Points;* they are also denominated the *Nodes of the Equator;* and the straight line conceived to join them is the *Line of the Equinoxes,* or the *Line of the Nodes.* The node through which the sun passes on coming from the south to the north of the equator is called the *Ascending Node,* and is usually distinguished by the character ☊; the opposite node is the *Descending Node,* and is marked by ☋. A straight line passing through the centre of the earth, perpendicular to the plane of the ecliptic, is called the *Axis of the Ecliptic,* and the points in which its prolongation meets the sphere are called its *Poles*—these denominations being analogous to those of the axis and poles of the equator. The two small circles of the sphere which pass through the poles of the ecliptic, and are parallel to the equator, are called the *Polar Circles.*

Zodiacal signs. The ecliptic has been divided by astronomers, from time immemorial, into twelve equal parts, called *Signs,* each of which consequently contains 30 degrees. The names and symbols by which they are characterised are as follows :—

North of the Equator.		South of the Equator.	
Aries, ...	♈	Libra, ...	♎
Taurus, ...	♉	Scorpio,..............	♏
Gemini,............	♊	Sagittarius,.........	♐
Cancer, ...	♋	Capricornus, ...	♑
Leo, ...	♌	Aquarius............	♒
Virgo,....	♍	Pisces, ...	♓

In each of these signs the ancients formed groups of stars, which they denominated the *Zodiacal constellations* (*ζώδια, animals*), not confined to the ecliptic, but included within an imaginary belt, extending 9° on each side of it, to which they gave the name of *Zodiac* (*ζωδιακός κύκλος, circle* or *zone of the animals*). The term *sign* is now employed only to denote an arc of 30°, and will probably soon be banished entirely from astronomical tables. It is now seldom used even for tables of the planets. Formerly, to denote that the longitude of a planet is 276° 12′, it was usual to write $9^s\ 6°\ 12'$; or even to employ the characteristic symbol, and to write ♑ 6° 12′, meaning that the planet was 12′ in the 6th degree of Capricornus, or the tenth sign. The latter inconvenient practice is now laid aside, and the signs, when they are employed, are simply distinguished by the ordinal numbers.

As the greater part of the celestial phenomena connected with the planetary system take place either in the ecliptic or in planes not greatly inclined to it, it is found to be most convenient to refer the positions of the planets, and frequently those of the stars also, to that plane. The first point of Aries, which is the technical expression for the intersection of the ecliptic and equator, or the place of the sun at the vernal equinox, is assumed as the origin from which the degrees of the ecliptic, as well as of the equator, are counted from west to east, or in the direction of the sun's annual motion. The angular distance of the sun **Celestial latitude and longitude.** from this point is called his *Longitude,* and the longitude of a star is the arc intercepted on the ecliptic between the same point and a great circle passing through the star perpendicular to the ecliptic. The arc of this circle intercepted between the star and the ecliptic, or, which is the same thing, the complement of the star's distance from the pole of the ecliptic, is called the *Latitude* of the star; so that longitude and latitude bear the same relation to the ecliptic that right ascension and declination bear to the equator.

The sun's motion along the ecliptic is found not to be strictly uniform, a circumstance into which we shall have to inquire more particularly farther on. In this place, let it suffice to notice that the sun is found to move more quickly in winter than in summer, the rate of motion changing from its maximum nearly in mid-winter to its minimum nearly in midsummer, and thence to its maximum again. But at no time does the motion differ greatly from its mean rate of very nearly 59′ in a sidereal day. If we call the mean rate 10,000, then the greatest and least rates of motion are represented by the members 10,336 and 9664 respectively.

The direction in which the sun travels round the ecliptic, and in which longitude is measured, is from west to east, that is, it is contrary to the direction in which the star-sphere rotates.

CHAPTER IV.—*The Solar Day—Equation of Time—The Seasons.*

Since the sun travels thus around the celestial sphere, it is manifest that the successive returns of the sun to the meridian cannot recur after the same interval of time as the successive returns of any given star. If on any day the sun's centre when he is crossing the meridian has a particular position on the star-sphere, then when that point of the star-sphere next returns to the meridian,—that is, one sidereal day later,—the sun has travelled about 1° from that point, moving along the ecliptic in a direction opposed to that in which the star-sphere rotates. The star-sphere must, therefore, rotate a little further round before the sun will be on the meridian. As a convenient first approximation to the actual effects, let us make the supposition that the sun moves along the equator instead of the ecliptic, and that he moves exactly 1° in a sidereal day. In this case he would be exactly 1° from the meridian when the point he had occupied on the meridian the day before had reached the meridian. That point on the star-sphere would have completed the full circuit of 360° of rotation while the sun had completed only 359°, and his diurnal motion being therefore only $=\frac{359}{360}$ of the star-sphere's, it follows that the solar day (or the interval between the sun's successive returns to the meridian) would be greater than the sidereal day in the ratio of 360 : 359. Therefore, the solar day being divided into 24 × 60 minutes, the sidereal day would manifestly be 4 min. shorter.

But as the sun moves in a circle inclined more than 23° to the equator, and as the sun's motion is slightly variable, and the mean rate less than 1° per sidereal day, these relations are not exactly presented.

Let us, as a next approximation, suppose the sun to move uniformly round the equator once in the course of a year of $365\frac{1}{4}$ days, and determine the length of a solar day on this assumption. It is clear that whatever the sun's daily retardation may be, he loses one complete circuit of the heavens in a year of $365\frac{1}{4}$ solar days. In other words, while the sun has been carried round $365\frac{1}{4}$ times by the diurnal rotation, the star-sphere has been carried round $366\frac{1}{4}$ times. Therefore, on our assumption

$$365\tfrac{1}{4} \text{ solar days} = 366\tfrac{1}{4} \text{ sidereal days}$$

$$\text{and a sidereal day} = \frac{365\frac{1}{4}}{366\frac{1}{4}} \text{ solar day}$$

$$23 \text{ h. } 56 \text{ m. } 4 \text{ s., approximately.}$$

This, in fact, indicates roughly the manner in which the mean solar day is connected with the sidereal day. It is only necessary in the above process to substitute the true length of the year for the value $365\frac{1}{4}$ days,—meaning by the year, the year of seasons, measured by the successive returns of the sun to the equator as he crosses that circle with northward motion. But it will not be until we consider the actual nature of the motion by which the sun's annual apparent motion is explained, that we need inquire into the exact relation between the mean solar day and the sidereal day.

Variations of sun's motion.

As the sun moves at a varying rate, it is manifest that the actual solar day measured by the successive returns of the sun to the meridian could not be constant in value, even if the sun moved round the equator. For the excess of a solar day over the sidereal day is caused by the motion of the sun on the star-sphere, and will be therefore greater or less according as the sun's motion on the star-sphere is greater or less. The actual solar day, therefore, exceeding the constant sidereal day by a variable quantity, must necessarily be itself variable. It is greater than the mean in December and January, when the sun is moving at a rate greater than his mean rate, and less in June and July when he moves at a less rate. And it is clear that if at the end of December the moment of the real sun passing the meridian were taken as the beginning of the mean solar day of twenty-four hours, then the next passage of the meridian by the actual sun would occur after the twenty-four hours of mean solar time had elapsed. Day after day the sun would come to the meridian at a later and later hour of mean solar time, until towards the end of March, when, the sun's rate having acquired its mean value, the actual sun would not lag any farther behind. From this time he would gain, until towards the end of June he would come to the meridian at noon of mean solar time. In the remaining half year he would be in advance, that is, he would cross the meridian before noon of mean solar time. Towards the end of September he would have made his greatest advance compared with mean time, and in the remaining quarter of the year he would gradually lose more and more of that gain, until at the end of December he would again cross the meridian at noon of mean solar time.

But besides this cause of variation in the length of the true solar day, there is another depending on the inclination of the sun's apparent path on the heavens to the celestial equator. To conceive the effect of this cause, it is necessary to have regard to the motion of the sun with reference to the equator. The sun describes every day a small arc of the ecliptic. Through the extremities of this arc suppose two meridians to pass; the arc of the equator, which they intercept, is the sun's motion for that day referred to the equator, and the time which that arc takes to pass the meridian is equal to the excess of the astronomical day over the sidereal. But it is obvious that at the equinoxes the arc of the equator is smaller than the corresponding arc of the ecliptic, in the proportion of the cosine of the obliquity of the ecliptic; at the solstices, on the contrary, it is greater in the proportion of the secant of the same obliquity. The astronomical day is diminished in the first case, and lengthened in the second.

Mean sun.

To have a mean astronomical day independent of these causes of inequality, astronomers have supposed a second sun to move uniformly on the ecliptic, and to pass over the extremities of the axis of the sun's orbit at the same instant as the real sun. This removes the inequality arising from the inequality of the sun's motion. To remove the inequality arising from the obliquity of the ecliptic, conceive a third sun to pass through the equinoxes at the same instant with the second sun, and to move along the equator in such a manner that the angular distances of the two suns at the vernal equinox shall be always equal. The interval between two consecutive returns of this third sun to the meridian forms the *mean astronomical day. Mean time* is measured by the number of the returns of this third sun to the meridian; and *true time* is measured by the number of returns of the real sun to the meridian.

Equation of time.

The arc of the equator, intercepted between two meridian circles drawn through the centres of the true sun and the imaginary third sun, when reduced to time, is what is called the *Equation of Time.* This will be rendered plainer by the following diagram.

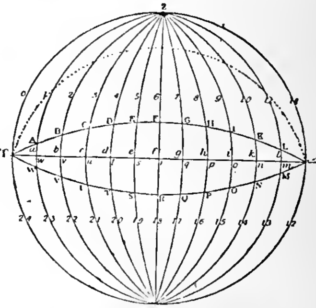

FIG. 13.—Motions of real and mean Sun.

Let Z ♈ z ♎ (fig. 13) be the star-sphere; Zz its axis; *abcde*, &c., the equator; ABCDE, &c., the northern half of the ecliptic from ♈ to ♎, on the side of the globe next the eye; and MNOP, &c., the southern half on the opposite side from ♎ to ♈. Let the points at A, B, C, D, E, F, &c., mark off equal portions of the ecliptic gone through in equal times by the real sun, and those at *a*, *b*, *c*, *d*, *e*, *f*, &c., equal portions of the equator described in equal times by the fictitious sun; and let Z ♈ *z* be the meridian.

As the real sun moves obliquely in the ecliptic, and the fictitious sun directly in the equator, any point between ♈ and F on the ecliptic must be nearer the meridian Z ♈ *z*, than the corresponding point on the equator from ♈ to *f*, that is to say, than the point whose distance from ♈ is expressed by the same number of degrees; and the more so, as the obliquity is greater; and therefore the true sun comes sooner to the meridian every day whilst he is in the quadrant ♈ F, than the fictitious sun does in the quadrant ♈ *f*; for which reason the solar noon precedes noon by the clock, until the real sun comes to F, and the fictitious to *f*: which two points being equidistant from the meridian, both suns will come to it precisely at noon by the clock.

Whilst the real sun describes the second quadrant of the ecliptic FGHIKL from Cancer to ♎, he comes later to the meridian every day than the fictitious sun moving through the second quadrant of the equator from *f* to ♎; for the points at G, H, I, K, L, being farther from the meridian, their corresponding points at g, h, i, k, l, must come to it later; and as both suns come at the same moment to the point ♎, they come to the meridian at the moment of noon by the clock.

In departing from Libra through the third quadrant, the real sun going through MNOPQ towards ♑ at R, and the fictitious sun through $mnopq$ towards r, the former comes to the meridian every day sooner than the latter, until the real sun comes to R, and the fictitious to r, and then they come both to the meridian at the same time.

Lastly, as the real sun moves equably through STUVW, from R towards ♈, and the fictitious sun through $stuvw$, from r towards ♈, the former comes later every day to the meridian than the latter, until they both arrive at the point ♈, and then they make it noon at the same time with the clock.

It is now easy to conceive the effect of taking into account the variable motion of the sun in his annual circuit of the ecliptic. The effect already explained as arising from this cause, on the supposition that the sun moved in the equator, must simply be added to that just shown to arise from the obliquity of the ecliptic.

Let us combine the two causes, starting from December 31, on the assumption (near enough to the truth for our present purpose), that the sun moves most rapidly when at his greatest southerly declination. The effect due to variation of the sun's motion may be called A, and that due to the obliquity of the ecliptic may be called B; and each may be considered positive or negative according as, considered alone, it sets the real sun later or earlier than the mean sun.

We find, then, from January 1 to March 31, A and B both positive, A increasing from 0 to its maximum, B passing from 0 through its maximum to 0 again. All this time, then, $A+B$ is positive. At the beginning $A+B=0$. About the middle of February B has its maximum value, and A a value less than its maximum; at March 31, B is zero and A has its maximum value.

From April 1 to June 30, A is positive and B negative, A diminishing from its maximum to zero, B passing from 0 through its maximum negative value to 0 again. At the beginning, then, of this quarter, $A+B$ is positive and equal to the maximum value of A. In the middle of May, B has its maximum negative value, and A has a value less than its maximum positive value. The maxima due to A and B being not far from equality, it follows that $A+B$ is now negative, and therefore some time before this $A+B$ must have passed through the value 0. At the end of the quarter $A+B$ is again 0, because $A=0$ and $B=0$.

From July 1 to September 30, A is negative and B positive, A increasing from 0 to its maximum negative value, B passing from zero through its maximum positive value to zero again. Hence, at the beginning of the quarter $A+B=0$; at the end $A+B=$ the maximum negative value of A. But about the middle of August, B has its maximum positive value while A has not its maximum negative value; hence at this time $A+B$ is positive, and therefore between then and September 30, $A+B$ vanishes.

Lastly, from October 1 to December 31, both A and B are negative, A passing from its maximum value to zero, and B from zero to its maximum value, and thence to zero again. Throughout the quarter, then, $A+B$ is negative. About the middle of November $A+B$ is the sum of the maximum value of B and a value of A less than the maximum. At the end of the quarter $A+B=0$.

Owing to the fact that the time when the sun moves most rapidly follows by a few days the date (December 21) when the sun is at his greatest distance from the meridian, the dates above given are not strictly correct. The equation of time, or $A+B$, is zero nearly midway between December 21 and the end of the year, or about Christmas day, and it vanishes again on or about April 16, June 16, and September 1st. The equation of time has four maxima. On February 11, the real sun is later than the mean sun by a maximum interval of 14 min. 31 sec.; on May 14, the real sun is earlier than the mean sun by a maximum interval of 3 min. 53 sec.; on July 16, the real sun is later than the mean sun by a maximum interval of 6 min. 13 sec.; and lastly, on November 3, the real sun is earlier than the mean sun by a maximum interval of 16 min. 19 sec.

The inclination of the ecliptic to the equator results necessarily, as already mentioned, in a difference of seasons. The seasons.
When on the equator, the sun, like an equatorial star, is above the horizon during one-half of the day, and below the horizon during the other half. When he is north of the equator he is above the horizon for more than half the day, and reaches a higher altitude at noon than when on the equator. When south of the equator he is below the horizon for more than half the day, and does not reach so great an altitude at noon as when he is on the equator. As he is perceptibly the source of light and heat, it follows that when he is north of the equator we receive (in our northern latitudes), more light and heat than when he is on the equator, and so much the more as his northerly declination is greater; while when he is south of the equator we receive less light and heat than when he is on the equator, and so much the less as his southerly declination is greater. These results are equally accounted for whether we regard the earth as fixed, and the sun as really travelling round the heavenly sphere on his inclined path, or whether we suppose the sun to be fixed, and the earth to travel around him on a correspondingly inclined path after the manner illustrated in fig. 14. Here, while the earth

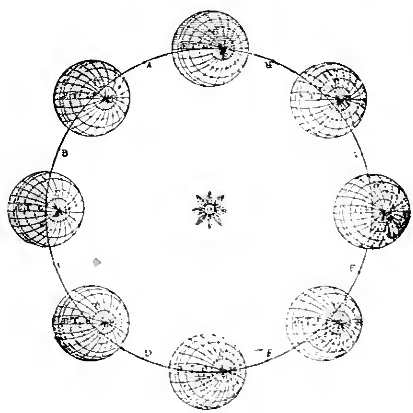

FIG. 14.—Diagram illustrating the Seasons

goes round the sun in the order of the letters A, B, C, D, its axis preserves its obliquity and always continues parallel to its first direction. At c the north pole inclines towards the sun, and brings all the northern places more into the light than at any other season of the year. But when the earth is at g, the opposite point of the orbit, the north pole declines from the sun, and a less portion of the northern hemisphere receives his light and heat. At *a* and *e* the axis is perpendicular to the plane of the orbit, so that the poles are situated in the boundaries of the illuminated hemisphere, and, the sun being directly over the equator, the days and nights are equal at all places. In this figure Æ is the terrestrial equator, T the tropic of Cancer, the dotted circle the parallel of London, U the arctic or north polar circle, and P the north pole, where all the meridians or hour-circles meet. The spectator is supposed to be placed at the pole of the ecliptic.

It is also manifest that if the earth circles around S, as in fig. 14, the observed phenomena of apparent solar motion will be precisely the same as though the sun circled around the fixed earth. Let us follow the earth round from the position *a*, noting how the sun would appear to move on the ecliptic, and also how the length of day would be affected by the varying position of the earth's axis with respect to the sun. When the earth is at *a*, the beginning of Libra, about the 20th of March, the sun, as seen from the earth, appears at the beginning of Aries in the opposite part of the heavens, the north pole is just coming into light, and the sun is vertical to the equator, which, with all its parallels, is divided into two equal parts by the circle which forms the boundary between the dark and illuminated hemispheres, and therefore the days and nights are equal all over the earth. As the earth moves in the ecliptic, according to the order of the letters A, B, C, D, &c., the north pole P comes more and more into the light, and the days increase in length at all places north of the equator Æ. When the earth comes to the position between B and C, or the beginning of Capricorn, the sun, as seen from the earth, appears at the beginning of Cancer about the 21st of June; and the north pole of the earth inclines towards the sun, so as to bring into light all the north frigid zone, and more of each of the northern parallels of latitude in proportion as they are farther from the equator. As the earth advances from Capricorn towards Aries, and the sun appears to move from Cancer towards Libra, the north pole recedes from the light, which causes the days to decrease and the nights to increase in length till the earth comes to the beginning of Aries, and then they are equal as before,—the boundary of light and darkness cutting the equator and all its parallels equally. The north pole then goes into the dark, and does not emerge till the earth has completed a semi-revolution of its orbit, or from the 22d of September till the 20th of March. Similar changes occur, *mutatis mutandis*, in the southern hemisphere.

It may be well to advise the reader not to allow his mind to be led astray by the *proportions* indicated in such pictures as fig. 14. It is absolutely impossible to illustrate the seasons, either by diagrams or by the use of a globe, without introducing incorrect relative dimensions; but by combining two sets of pictorial illustrations, the mental error apt to arise from the study of such pictures as fig. 14 may be got rid of. Thus, after carefully studying the relations illustrated in that figure, the reader should turn to Plate XXVII., and after noting that the figure of the earth there shown is the same as that in fig. 14 (held so as to have G*g*F uppermost), he should endeavour to picture to himself such a figure of the earth as is shown in the plate, travelling around the path EE′, but so reduced in dimensions that its whole disk would have a diameter less than the hundredth part of that of the small white disk, at the centre of the plate, which represents the sun. It will then be instructive to extend this method to Mars, as figured in Plate XXVII., carrying this planet (after first imagining his disk reduced 5000 times) round his path MM′, with constant axial pose. The planets pictured in Plate XXVIII. can be dealt with in like manner. From a careful study of the two plates, with special reference to the indicated scales, the general relations of the entire solar system can be inferred, and to some degree conceived. But for the purpose of actually picturing these relations to his mind, the reader may conveniently use Sir J. Herschel's illustration, as follows:—Choose any well-levelled field. On it place a globe 2 feet in diameter to represent the sun; Mercury will be represented by a grain of mustard seed, on the circumference of a circle 164 feet in diameter for its orbit; Venus a pea, on a circle 284 feet in diameter; the earth a [somewhat larger] pea, on a circle of 430 feet, Mars a rather large pin's head, on a circle of 654 feet; the asteroids grains of sand, in orbits of from 1000 to 1200 feet; Jupiter a moderate-sized orange, on a circle of half a mile; Saturn a small orange, on a circle of $\frac{4}{5}$ths of a mile; Uranus a full-sized cherry, on a circle more than $1\frac{1}{2}$ miles; Neptune an extra-sized cherry, on a circle of $2\frac{1}{2}$ miles in diameter.

CHAPTER V.—*Apparent Motions of the Moon and Planets—Parallax.*

We have seen that while the stars remain fixed, to all appearance, on the celestial concave, the sun circuits around a great circle of the star-sphere, moving always in one direction, and at a rate which, though variable in different parts of the circuit, does not vary largely, and is constant for each part of the ecliptic. Moreover, to ordinary observation, continued for periods of a few years, the sun's path in the heavens appears to remain always the same, and to bear the same relation to the poles and equator of the rotating star-sphere.

But we have now to consider bodies which neither remain fixed like the stars, nor move in a constant apparent path like the sun.

The moon is the most noteworthy of these bodies, because of her apparent size and brightness, and also because of the remarkable changes of appearance which she presents according to her varying position with reference to the sun. When she is seen near him in the heavens, she appears always like a fine sickle of light, with the horns turned away from him. When she is in the part of the heavens directly opposite to the sun, she appears with a full orb. When she is exactly midway between the point occupied by the sun and that opposite to him, she appears as a semicircle of light, with the convexity towards the sun; and in positions intermediate to these she appears with more or less of her circle illuminated, according as she is nearer to or further from the point directly opposite the sun. All this corresponds with what would happen if the moon were an opaque orb nearer to the earth than the sun, and illuminated by him. Moon's phases.

Now, when the moon is watched, even for a few hours only, she is found to be travelling on the star-sphere in the same direction as the sun (and, like him, on a path inclined to the equator), but much more rapidly than the sun travels. It is impossible to watch the moon completely round the heavens, because she is found to pass close to the sun once in each circuit, and when very near to him cannot be seen. But while she is visible, she travels continuously in one direction, and when she reappears, after having been for a day or two lost in the sunlight, she is seen to have shifted her place as though, during that interval, she had travelled continuously onwards.

The moon's circuit of the star-sphere is found to be completed in about $27\frac{1}{3}$ solar days. But her circuit, considered with reference to the sun, occupies a longer interval. Thus, suppose we observe her when she is opposite to the sun, or "full." Then she is in the same (or very nearly the same) place among the stars about $27\frac{1}{3}$ days later. But in the meantime the sun has advanced along the ecliptic Sidereal month.

about 27°, and the point now directly opposite the sun has, of course, advanced by the same amount. The moon has, therefore, to travel further on before she is again exactly opposite the sun. It is found that this happens rather more than 2 days later; or in other words, that the interval between successive full moons amounts to about $29\frac{1}{2}$ days. This interval is called a *lunar month*, or *lunation;* the period during which the moon completes the circuit of the heavens being called a *sidereal month.* The lunation is also called a *synodical month.*

Lunar orbit. The path in which the moon travels is found to be inclined at an angle of about 5° 9′ to the ecliptic. But continued observation shows that the path, while retaining this inclination, shifts slowly in position—the points where it intersects the ecliptic gradually retrograding (on the whole) until, in the course of about $18\frac{1}{2}$ years, they have made a complete circuit of the ecliptic. It is also found that the moon moves, like the sun, with variable velocity in her apparent course. The parts of her path, however, where she moves most and least rapidly are not fixed in position like the corresponding parts of the sun's apparent circuit, but advance, travelling round in 8·85 years.

It follows, from the varying position of the moon's apparent path with respect to the ecliptic, that her range north and south of the equator is variable. When she crosses the ecliptic, at or near the two points where the ecliptic crosses the equator, the inclination of her path to the ecliptic is either added to or subtracted from the inclination of the ecliptic to the equator, so that her range in declination is, in one case, 23° 27′ + 5° 9′, or 28° 36′, and in the other, 23° 27′ − 5° 9′, or 18° 18′. When she crosses the ecliptic at or near the two points where the ecliptic is furthest from the equator, the inclination of her path to the equator is nearly the same as that of the ecliptic, the two paths—the ecliptic, or sun's path, and the apparent lunar path—crossing the equator at different points.

Thus far there is nothing in the observed celestial motions which opposes itself to the belief that the earth is a fixed centre around which the celestial bodies are carried—the star-sphere by the diurnal rotation, the sun circling round the earth in his yearly course on the ecliptic, and the moon in her monthly (lunar) course on a variable path, and both these orbs partaking in the diurnal rotation of the star-sphere, just as bodies in a moving vehicle partake in the motion of the vehicle, even though they may also be in motion among themselves.

One circumstance in the moon's apparent motions serves, however, to show that the bodies thus far observed lie at different distances, and falls properly to be considered in this place, seeing that the attention of astronomers must first have been directed to it when they were engaged in determining the moon's motions.

The earth being, as we have seen, a globe, and the sun and moon being apparently carried round this globe by the daily rotation, which is uniform, it would naturally occur to astronomers that, if these motions take place around the centre of the earth, they cannot appear altogether uniform as seen from the eccentric position of an observer placed anywhere on the surface. The stars, indeed, seem to be carried uniformly round, but that has been explained as due to their enormous distance. The sun moving manifestly within the stellar concave, and the moon travelling

Lunar parallax apparently within the sun's orbit (as may be inferred from her phases), it might well be that their motions would be found affected by the eccentricity of the observer's position. Suppose, for example, that the centre of the earth is at P, fig. 15, and the observer is at E, and let EM_h represent a line of sight from E to the moon's centre when she is in the horizon (refraction being neglected). Then a line PM_h from the centre of the earth to the moon is inclined to the horizon line EM_h; and if we draw Pm_h parallel to EM_h so that either line represents the direction of the moon as observed from E, we see that, if she were observed from P, she would appear *raised* by the angle included between the lines PM_h and Pm_h. From E, then, she is seen lower down than her true geocentric position by the angle M_hPm_h; and similarly it is seen that, if the moon be at M, the direction EM in which she is seen is lower down

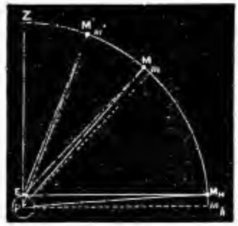

Fig. 15.—Diagram illustrating Lunar Parallax.

—that is, is less inclined to the horizon line Em_h—by the angle EMP, or its equal, MPm; if the moon were at M′, the displacement would be equal to the angle EM′P, and only when she is at the zenith Z does her direction EZ agree with her geocentric direction PZ. Her observed path from horizon to horizon, when she rises high in the south, but does not reach the zenith, will be as the path $m_1m_3m_5$ (fig. 16), where her geocentric path is as $M_1M_3M_5$. This will happen if she is near enough to the earth for the angle EM_hP (fig. 15), to be appreciable; and all that has here been said of the moon is equally true of the sun.

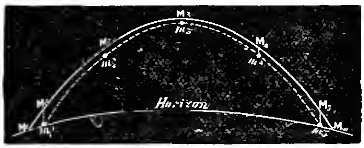

Fig. 16.—Observed and Geocentric Paths of the Moon.

or any other celestial body. But in their case no appreciable displacement occurs (at least none which the earlier modes of observation could indicate). In the case of the moon the displacement is very marked, being found to amount nearly to a degree when the moon is on the horizon. Such displacement is called *parallax.* Thus, when any celestial body is at M (fig. 15), the angle EMP (or MPm), between the geocentric direction PM, and the apparent direction EM, is called the parallax of the body. When the celestial body is at M_h, so that its true direction is horizontal, the parallax EM_hP, is manifestly greater than for any other position of the body at the same distance from P. This maximum parallax is called the *horizontal parallax*, and may be defined as the maximum angle subtended by the earth's radius, as supposed to be seen from the body.

It may be noticed, in passing, that if the geocentric distance of a celestial body $= d$, the earth's radius $= r$, and the horizontal parallax $= p$, then Parallax.

$$\sin p = \frac{r}{d} \qquad (1).$$

This is manifest from fig. 15, where $\sin PM_hE = \frac{EP}{PM_h}$.

Again, in the case of a body at M, using the same symbols, and calling the apparent altitude MEM, a, and the parallax p', we have

$$p' = MPm$$

$$\sin p' = \frac{EP \sin EPm}{MP} = \frac{r \sin a}{d}$$

That is, $\sin p' = \sin. a \ \sin. p \quad . \quad . \qquad (2).$

For every celestial body, except the moon, the parallax is so small that its arc-measure may be substituted for its sine; hence, for (1) and (2) we may write

$$p = \frac{r}{d} \quad . \ . \ . \ . \ (3); \quad \text{and } p' = p \sin. a \quad . \ . \ (4),$$

for all the heavenly bodies except the moon.

From the observed parallactic displacement of the moon it is manifest, apart from the lunar phases, that the moon's orbit relatively to the earth lies within the sun's.

We have now, however, to consider bodies which, if they be regarded as moving around the earth, must move in orbits of very singular shape.

Planetary motions.

While observing the stars, which maintain apparently a constant position on the uniformly rotating star-sphere, the ancients early noted five bodies, which seem to travel among the stars like the sun and moon, but not always in one direction. To these bodies they gave the name of planets, or wanderers (a term which also included the sun and moon, so that there were seven in all). Three could be seen sometimes throughout the night, sometimes in the

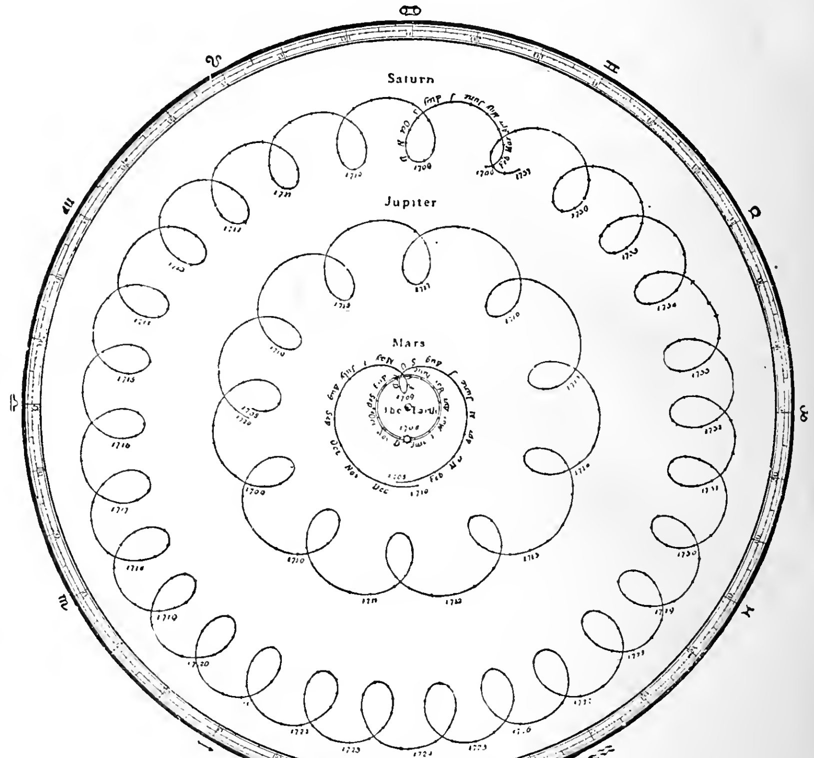

FIG. 17.—The Motion of Saturn, Jupiter, and Mars with respect to the Earth.

morning, sometimes in the evening. To these were given the names Saturn, Jupiter, and Mars; and careful observation showed that these bodies, when visible all through the night, always travel among the stars in a direction contrary to that of the sun's yearly and the moon's monthly motion, but that this retrograde motion continues only for a certain length of time, being preceded and followed by an advancing motion, which is greater in amount than the retrograde motion, so that, on the whole, these bodies are carried round in the same direction as the sun and moon. The nature of these apparent motions will best be understood by referring to fig. 17, and supposing an observer on the earth to watch Saturn, Jupiter, and Mars respectively traversing the twisted paths there indicated, in the order shown by the dates, the loops being supposed to lie very nearly but not quite in the level of the paper, which represents the plane of the ecliptic. But this peculiarity was noticed, that when any planet was at the outermost parts of the successive loops (as, for instance, when Jupiter was as where the date 1712 is placed on his loops), the planet was lost to view in the sun's rays, lying nearly in the same part of the sky, whereas, when a planet was at

the innermost parts of the successive loops (as, for instance, when Saturn was as where the date 1710 is placed on his loops), the planet was always opposite the sun. This exact agreement between the times when the planet and sun were in *conjunction* or in *opposition*, and the tracing out of the apparent planetary loops, should have suggested, it would seem, a connection between the sun and planets; for we see from fig. 17, that if the earth were the centre of the sun's motion, and each of the three planets had its looped path wherein to travel around the earth, there could be imagined no reason why the planet's motion round its loops should synchronise with the sun's motion on his nearly circular path.

This view should have been confirmed by the apparent motions of two other planets, Venus and Mercury, which were found to remain always within a certain apparent distance from the sun, never being seen on the part of the sky opposite to him. Venus, the brighter, was observed to have the greater range on either side of the sun, moving from about 46° on the east of the sun, when she is seen as the Evening Star, to about the same distance on the west of the sun, when she is seen as the Morning Star; while Mercury's greatest range on either side of the sun is more variable, being sometimes as great as 27°, and at other times not greater than 18°. So far as the motion of these planets on the star-sphere could be traced (by using such an instrument as in fig. 9 to determine their right ascension and declination), they appeared to follow looped paths, somewhat like the outer planets; but the nearer and farther parts of the successive loops were *both* lost to view, the two planets being always too near the sun's place in the heavens to be visible when tracing those parts of their paths.

The five planets were found to travel always within a certain range on either side of the ecliptic. Venus, which has the greatest range, being sometimes as far as 9° north, or 9° south of the equator. A zone, or band, having the ecliptic for its central circle, and bounded by circles 9° north and south of the ecliptic, so as to be 18° wide, came thus to be regarded as a sort of celestial roadway, outside of which the planets were never seen. This zone was called the *zodiac*, and it was probably in connection with the planetary rather than the solar motions that the zodiacal constellations were originally formed.

Considering the observed relation between the motions of all the five planets and those of the sun, it is remarkable that any of the astronomers of old time should have regarded the earth as the common centre of solar and planetary movement. It is true that, by supposing each planet to travel around a centre which itself travelled round the earth, the looped paths of the planets might be explained; of this no further evidence need be given than fig. 17, where it is manifest that the loops are such as might be traced by bodies moving round small circles, these being carried round the central earth in large circles. Yet the synchronism between all the movements in these small circles and the sun's supposed motion round the earth was left wholly unexplained by that theory. If the Ptolemaic system could have been really presented as it is commonly pictured (fig. 18), it would have compared not unfavourably with the simplicity of the modern system. But the circles depicted in this figure for the paths of Saturn, Jupiter, Mars, Venus, and Mercury, represent only the paths of moving centres, round which those bodies were supposed to travel, each in a circle of its own, and all synchronising in these subordinate movements with the sun circling in his special orbit; while the movements of the moon, travelling in a different circle, neither corresponded in any way with those of the sun, nor, like his, seemed to influence any of the planetary motions.

Ptolemaic system.

Far more reasonable was the ancient Egyptian system, by some described as identical with, but in any case closely

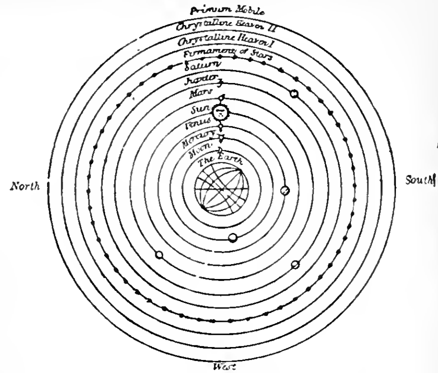

Fig. 18.—Ptolemaic System.

resembling in essentials, the system of Tycho Brahe, shown in fig. 19. Here the earth is the centre of the motions of the sun and moon, but all the planets circle around the sun, Venus and Mercury moving in orbits passing between the earth and sun, while Mars, Jupiter, and Saturn move in orbits passing outside the earth. All the observed movements, and all the peculiarities of the observed relations, were fully explained by this system. Indeed, a

Tychonic system.

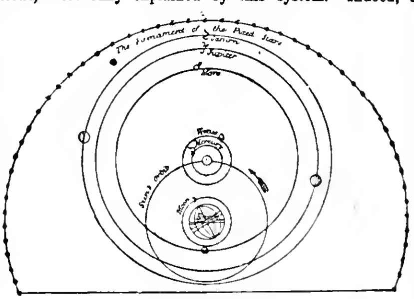

Fig. 19.—Tychonic System.

little consideration will show that the geometrical relations are precisely the same for such a system as is depicted in fig. 19, as they would be in the system pictured by removing the circle showing the sun's orbit in fig. 19, and substituting a circle of equal size around the sun as centre and passing therefore through the centre of the earth. It is not too much to say that Tycho's system is not only fully equal to the Copernican in its fitness to explain the observed relations, but that, until the law of gravitation had been established, the arguments for the Tychonic system, modified so as to correspond to Kepler's discovery of the shapes of the different orbits, were almost equal in weight to those used by the disciples of Copernicus. The slight advantage of the Copernican system in point of simplicity was counterbalanced by the difficulty of accepting, in those days, the belief that the stars lie at so inconceivably vast a distance that the motion of the earth in an enormous orbit around the sun (for the sun was known even then to lie many millions of miles from ns) produces no perceptible change in the appearance and rotation of the star-sphere. That the whole span of the earth's orbit was as a mere point compared with the distance of the stars, so that the earth on one side of the sun was, in effect, at the centre of the star-sphere, while it was equally at the centre when on the opposite side, or many millions of miles from its former position, was not unreasonably regarded by Tycho Brahe as scarcely credible.

CHAPTER VI.—*Copernican System—Kepler's Laws—Gravitation—The Laws of the Solar System.*

Leaving the rotation of the star-sphere out of consideration, the apparent motions of the sun, the moon, and the five planets known to the ancients, are most naturally explained by regarding the sun as the centre around which Mercury, Venus, the earth, Mars, Jupiter, and Saturn revolve in that order as to distance, while the moon revolves round the earth. For though there are thus two centres of motion yet only a small body travelling in a relatively small orbit is set revolving round the earth, now presented as a subordinate orb in the system; and the whole family, including the moon, are set revolving around the sun, for the moon accompanies the earth in her circuit. In the Tychonic system the sun, though presented as a subordinate orb, because travelling round the earth, was yet set as the centre round which all the planets revolved. Either system was, however, altogether more reasonable than the Ptolemaic, in which all the planets were supposed to move around imaginary centres. Copernicus well indicated the superiority of his system when he said, "We find in this arrangement what can be discerned in no other scheme, an admirable symmetry of the universe, an harmonious disposition of the orbits. For who could assign to the lamp of this beautiful temple a better position than the centre, whence alone it can illuminate all parts at once? Here the sun, as from a kingly throne, sways the family of orbs that circle around him."

Theory of Copernicus. It is hardly necessary to point out that the arrangement suggested by Copernicus explains the motions of the sun and moon as readily as the system which presents both these bodies as moving around the earth. Peculiarities in the motions of the earth and moon are indeed left unaccounted for by a simple theory of uniform circular motion around the sun and earth as centres; but so they were in the Ptolemaic system until eccentric and epicyclic movements were provided, and these were as admissible in the Copernican theory as in the Ptolemaic. It is easy to show also that the general motions of the planets—their progressions, stations, retrogressions, &c.—were explained by the Copernican system. Thus, let S (fig. 20) be the sun, $E_1E_2E_3$, &c., the earth's orbit, $P_1P_2P_3$, &c., part of the orbit of a superior planet; and when the earth is at E_1 let the planet be at P_1, so that the planet is in opposition to the sun when at P_1. Starting from these positions, suppose that the earth and planet in the same interval of time pass over the arcs E_1E_2 and P_1P_2, E_1E_2 being greater than P_1P_2. Then obviously E_2P_2 is inclined to E_1P_1; and if these two lines are produced they will meet beyond P_1. Let them be produced beyond their point of intersection O to K_1, K_2 respectively; then the observer on the earth sees the planet in direction E_1K_1 when the earth is at E_1, and in direction E_2K_2 when the earth is at E_2. Hence the planet appears to have moved in direction K_1K_2 or backwards, though it has really moved in direction P_1P_2. Carrying the earth on with her more rapid motion, it is obvious that we come to a part E_3E_4 of the earth's orbit, where her motion is so inclined to the line of sight E_3P_3 or E_4P_4 to the planet, that the effect of the earth's more rapid motion is neutralised, and these lines of sight are parallel. At this time, then, the planet neither seems to advance nor retrograde, but appears to be *stationary*. After this it is manifest that

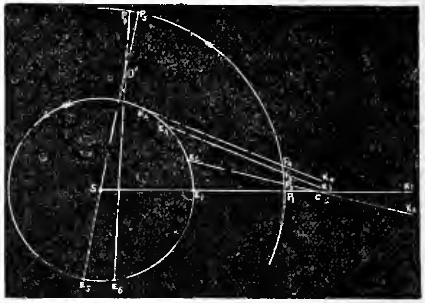

FIG. 20.—Diagram illustrating Apparent Paths of Planets.

the planet will seem to advance, and with gradually increasing rapidity, until when the earth is at E_5 and the planet at P_5 (the planet, however, being then in *conjunction* with the sun, and therefore invisible), the planet lies in direction E_5P_5 far in advance of K_1, K_2. At this time the unseen planet is advancing most rapidly, because the earth's motion, as from E_5 to E_6, and the planet's motion, as from P_5 to P_6, *combine* to cause the advance of the direction of the line E_6P_6,—the centre round which for the moment the direction-line to the planet is turning lying at O′ between the earth and planet, instead of beyond the planet, as at O in the position first considered. Passing from conjunction to opposition, the planet goes through similar changes in a reverse order. Its progressive motion gradually diminishes, till it becomes stationary; thence the planet retrogrades through opposition to its next station; and so on continually, the total result of its motion in each synodical revolution being a progression from west to east. We see also that the planet is in opposition when in the middle of its retrograde arc, while it is in conjunction when in the middle of its larger arc of progression. All this corresponds precisely with the observed relations.

The same reasoning applies to the case of an inferior planet. In fact, we may employ the same figure for this case as for that of a superior planet. Thus, suppose $P_1P_2P_3$ (fig. 20) the earth's orbit, and $E_1E_2E_3$, &c., that of an inferior planet, and let the motions be as in the former case, then the same lines represent the direction-lines, only the observer looks along these lines in the contrary direction. Now we see that the direction-lines P_1E_1, P_2E_2 are carried *backwards* as viewed from P_1, P_2, until they reach the parallel positions P_3E_3, P_4E_4, at which time the observer on P sees the planet E at a stationary point. After that the direction-lines are carried forward, until, when the earth is at P_5 and the interior planet at E_5, this planet is seen in direction P_5E_5, or far in advance of its former direction P_1E_1. And at this time, as is seen by the position of the lines P_5E_5 and P_6E_6, the inferior planet is advancing most rapidly. In fact, all the motions of an inferior planet viewed from a superior one are precisely the same as those of the superior planet viewed from the inferior one, but are traced out on opposite parts of the heavens,—a thesis which needs no other proof than the fact, that the line of sight from the inferior to the superior planet is also the line of sight from the superior to the inferior planet; so that, whatever point the superior planet viewed from the inferior appears to occupy in the star-sphere at any moment, the point directly opposite is that occupied by the inferior planet as viewed from the superior.

The only difference in the apparent motions of the inferior planet is that resulting from the position of this planet with respect to the sun. When P_1 is viewed from E_1 (fig. 20), it is seen directly opposite the sun; but E_1 viewed from P_1 lies in the same direction as the sun, and is therefore invisible. This corresponds with the observed fact that Venus and Mercury are in conjunction with the sun, not only in the middle of their advancing arcs, but also in the middle of their arc of retrogradation.

But although the Copernican theory explains the general features of planetary motion, it could not, as originally advanced, explain those features which had rendered necessary the eccentrics and the subordinate epicycles of the Ptolemaic system. It was known to Copernicus that the earth does not move uniformly in a circle around the sun as centre, but on an eccentric path with varying velocity. He might, therefore, reasonably assume that the other planets have paths similarly eccentric, and move with varying velocities. But he thought it necessary to explain the planetary motions by uniform motion in circles, using such contrivances to save appearances as the Ptolemaic system had rendered familiar to astronomers. Suppose, for example, that S (fig. 21) is the sun, A the place of a planet when at its greatest distance from the sun, and A′ its

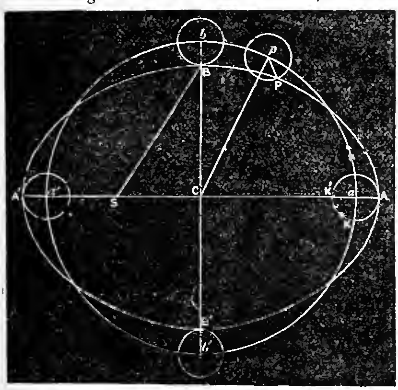

Fig 21.

place when nearest to the sun, C being the bisection of AA′; draw a circle $aba'b'$ with centre C, and any radius less than CA, and with a as centre draw circle AKK′; then if a point revolve round the circle AKK′ in that direction *in the same time* that the centre of this circle travels round the circle $aba'b'$ in that direction, the point will trace out an ellipse, having C as centre. This is easily proved. For let $Ca = R$, $aA = r$, and put $CA = R + r = a$ and $CK' = R - r = b = CB$. When the moving point is at P, let the centre of the small circle be at p. The angular velocities being equal, pC and pP are inclined to aC at the same angle; let this be α. Then the co-ordinates of P parallel to CA and Cb are—

$$x = (R + r)\cos.\alpha = a\cos\alpha$$
$$y = (R - r)\sin.\alpha = b\sin.\alpha$$

Whence $b^2x^2 + a^2y^2 = a^2b^2$, the equation to an ellipse having C as centre, CA and CB as semi-axes. S will not be the focus of this ellipse, unless $SB = CA$; and even then the velocities will not be those observed of a planet revolving around S in the elliptic orbit ABA′B′—for the time from A to B will be one-fourth of the period, whereas in the case of a planet the time from A to B bears to the period the ratio of the area ASB to the area of the ellipse, a ratio exceeding one-fourth. Nevertheless, observed appearances were to some degree explained by the motion illustrated in fig. 21, seeing that at A, or when farthest from the centre S, the tracing point moves most slowly, having there the difference of the velocities due to the two circular motions; while at A′ the point moves most quickly, having there the sum of these velocities. And when Copernicus advanced his theory, observations had not been made with sufficient exactness to prove the insufficiency of such an explanation in any case save that of the moon's motion round the earth.

Tycho Brahe, however, having completed a series of observations of Mars, the nearest planet moving on a manifestly eccentric orbit, Kepler tested the theory of Copernicus in order to ascertain whether any ellipse, described as ABA′B′ in fig. 21, could account for the observed positions of the planet. It will be seen that, while the points S, A, and A′ in his inquiry were fixed, and therefore C also fixed, the point a might be taken nearer or further from A within certain limits, these limits being determined by the observed fact, that when near B and B′ the planet was not nearer to C by a distance Bb exceeding a certain moderate amount, such as the probable error of Tycho Brahe's observations permitted Kepler to assume.

Laws of Kepler

It was after trying nineteen such arrangements, and rejecting them one after the other as he found them disproved by Tycho Brahe's observations, that Kepler was led at last to abandon the attempt to explain the motions of Mars by combining circular uniform motions. Passing to the ellipse, as the curve which Mars appeared to follow, and testing various empiric laws of motion in an elliptic orbit, he at length lighted upon the actual relation, presented in his first two laws as true for all the planets, though actually proved only in the case of Mars. The laws are these—

1. *Every planet moves in an elliptical orbit, in one focus of which the sun is situated.*

2. *The line drawn from the sun to a planet, or the radius vector of the planet, sweeps over equal areas in equal times.*

The second law may be thus illustrated. Let ABA′B′ (fig. 22) be the elliptic path of a planet about the sun S, in the focus of the ellipse whose axes are ACSA′ and BCB′

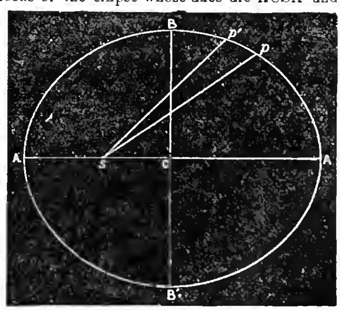

Fig 22.

Let P be the period in which the planet performs the complete circuit of its orbit, and let T be the time occupied by the planet in traversing any arc pp' of its orbit. Then joining Sp, Sp',

T : P : : sectorial area pSp' : area of the ellipse ABA′B′.

It remained now to discover if any law connected the periods in which the planets pursue their different paths. He did not at first try to connect the periods and the distances by any direct numerical relation, probably because he had recognised in the second law the probable existence of geometrical relations. But after many years of inquiry he arrived at the conclusion, that probably the required law connected the powers of the numbers representing the periods and the distances. It affords a strange evidence of the ponderous nature of Kepler's movements, that after this idea had occurred to him, ten weeks, instead of some ten minutes, elapsed before he had verified it. The law connecting the periods and distances—Kepler's third law—is this—

3. *The square of the numbers representing the periodic times of the planets vary as the cubes of the numbers representing their mean distances.*

Or thus, If D, d be the distances of any two planets, and P, p their respective periods, then

$$P^2 : p^2 :: D^3 : d^3 . \quad . \quad . \quad . \quad (1).$$

From this law we can deduce a convenient relation between the velocities in circular orbits (a relation holding approximately for the mean velocities in orbits nearly circular like those of the planets). Let V, v be the velocities in the orbits of planets whose distances are D, d respectively; then, obviously,

$$= c\frac{D}{P}, \text{ and } v = c\frac{d}{p}, \text{ where } c \text{ is some constant.}$$

$$\frac{V}{v} = \frac{D}{d} \cdot \frac{p}{P} = \frac{D}{d} \cdot \frac{d^{\frac{3}{2}}}{D^{\frac{3}{2}}} = \frac{d^{\frac{1}{2}}}{D^{\frac{1}{2}}} \quad . \quad . \quad . \quad (2),$$

that is, *the velocities in circular orbits vary inversely as the square roots of the distances.*

And also,

$$\frac{V}{v} = \frac{P^{\frac{2}{3}}}{p^{\frac{2}{3}}} \quad \frac{p}{P} = \frac{p^{\frac{1}{3}}}{P^{\frac{1}{3}}} \quad . \quad . \quad . \quad . \quad (3),$$

that is, *the velocities in circular orbits vary inversely as the cube roots of the periods.*

It may be well also to notice the following relation between the angular velocities in such orbits. Let these, for the respective planets just dealt with, be Ω and ω. Then,

$$\frac{\Omega}{\omega} = \frac{p}{P} = \frac{d^{\frac{3}{2}}}{D^{\frac{3}{2}}}$$

(It is manifest that $\frac{\Omega}{\omega} = \frac{p}{P}$, because the periods must be inversely proportional to the angular velocities with which they are uniformly described.)

The three laws of Kepler are approximately true for bodies circling around the same centre. They do not apply to bodies circling around different centres. For instance, the moon's distance and period could not be used for p and d in (1). Nor could the distance and period of any one of the satellites of Jupiter pair, according to Kepler's third law, with the distance and period either of our moon or of any planet; but the motions of the satellites were found to accord with the law when compared together.

Gravitation. It was probably the recognition of this fact which first put astronomers on the track of the theory that the law depends on some force residing in the centres round which different bodies move. Newton certainly had given attention to this influence before he dealt with the moon's attraction earthwards as a case of the action of terrestrial gravity. But, be that as it may, it is certain that so soon as the action of the earth's attraction on the moon had been demonstrated by him he extended the law of gravitation to all cases of motion around a central orb. It then became clear that the laws of Kepler are consequences of the general law of gravitation—the law, viz., that

Every particle of matter in the universe attracts every other particle with a force varying directly as the masses, and inversely as the square of the distances.

The proof of the law of gravitation divides itself into three distinct parts:—

First, The proof that the force acting on the moon is equal to the force of terrestrial gravity, reduced as the inverse squares of the distances of the moon and of a point on the earth's surface, from the centre of the earth.

Secondly, The proof that a system of bodies circling around a central body like the sun, attracting them with a force inversely proportionate to their respective distances, would obey the laws of Kepler, or some modification of those laws, giving results according with the motions actually observed.

Thirdly, The proof that the mutual attractions of the several members of any system, and the attractions of members of one system on bodies belonging to another system (as, for instance, of the sun upon the moon regarded as a dependent of the earth), would result in such perturbations from the paths due to the attractions of the central body as are observed actually to take place.

Neither the second nor the third of these arguments can be given here, though certain simple relations involved in them, as also certain consequences, will be mentioned.

The first part of the proof is altogether simple.

The moon is, roughly, at a distance from the earth's centre equal to 60 radii of the earth, and therefore the earth's moving force is less on her than on a body at the earth's surface as 1 to 3600. Now, regarding the moon's orbit as a circle, it is easily shown that, if at any moment the earth's attraction ceased to act, so that for the next second the moon moved on a tangent to her present course, her distance from the earth's centre at the end of that second would be rather more than $\frac{1}{19}$th of an inch greater than at the beginning of the second. It follows that her fall towards the earth in a second on account of the earth's attraction amounts to rather less than $\frac{1}{19}$ of an inch. But the fall of a body near the earth's surface is about $16\frac{1}{10}$ feet, or nearly 193 inches per second, or nearly 193×19 times greater than the fall of the moon towards the earth per second; that is, about 3600 times greater. In other words, the moon is attracted towards the earth precisely as she would be if the force of gravity acting on bodies near her surface ruled her also, the law of variation of the force with distance being that of the inverse squares.

The second part of the proof is simple for cases of circular motion of various bodies around a common centre. The law of the equable description of areas, indeed, is true for a body moving around a centre attracting according to any law, since it simply implies that there is no force perpendicular to the radius vector. It is easily seen that the increase of the area during any exceedingly short interval of time depends solely on the distance attained by the moving body during that interval from the line representing the position of the radius vector at the beginning of the interval, this distance being measured in a perpendicular direction; for the area of a triangle is measured by the base × perpendicular. Accordingly, if, during the short interval of time, there is no force tending to increase or diminish the perpendicular distance of the moving body from the original radius vector, as compared with the distance which would have been attained had no force at all acted, the area described will be the same as though no force had acted. But if no force acted, the body would move uniformly in a straight line, and the radius vector would sweep out equal areas, because triangles having the same vertex and their bases in one straight line have areas proportional to their bases. Hence, under a force not tending to change at any instant the rate of the moving body's perpendicular departure from the radius vector, the areas swept over in equal times will be equal. But a central force acts always in the direction of the radius vector, and is therefore a force of the kind supposed. Accordingly, a body travelling round an attracting centre will move so that the radius vector sweeps over equal areas in equal times.

Suppose next two bodies describing circles with uniform motion in periods P, p, at distances D and d from a centre of attraction whose force varies inversely as $(\text{distance})^2$. It is required to determine the relation between P, p, D, and d. The velocities of the bodies are $c\frac{D}{P}$ and $c\frac{d}{p}$, where c is some constant. Represent these velocities by V and v respectively for convenience; also call the forces acting on the bodies respectively F and f, which we know to be proportional to $\frac{1}{D^2}$ and $\frac{1}{d^2}$. Clearly, if a body moving in any direction receives a very slight impulse in a direction at right angles to its motion, its direction of motion will be changed through an angle proportional directly to the impulse and inversely to the velocity of the body. So that if we regard the attractive force on the planets as acting by a succession of small impulses, the momentary variation of direction is proportional to $\frac{F}{V}$, and the time, therefore, of completing any given change of direction is proportional to $\frac{V}{F}$. Now, in times P, p respectively, the two planets have their direction changed through four right angles. Hence

$$P : p :: \frac{V}{F} : \frac{v}{f} :: \frac{D}{P} \cdot D^2 : \frac{d}{p} \cdot d^2 .$$

That is, $P^2 : p^2 :: D^3 : d^3$, which is Kepler's third law.

Let us now compare the periods P and p of two bodies, moving at distances D and d, around unequal centres of force, which exert attractions A and a respectively at equal distances, so that instead of the forces F and f actually exerted on the two bodies being proportional to $\frac{1}{D^2}$ and $\frac{1}{d^2}$, they are proportional to $\frac{A}{D^2}$ and $\frac{a}{d^2}$ respectively.

Then the above proportion becomes

$$P : p :: \frac{D}{P} \cdot \frac{D^2}{A} : \frac{d}{p} \cdot \frac{d^2}{a}$$

That is, $$P^2 : p^2 :: \frac{D^3}{A} : \frac{d^3}{a}, \quad \text{or } P^2 \propto \frac{D^3}{A},$$

corresponding to a law which may be thus expressed: *The squares of the periods about different centres of force vary directly as the cubes of the distances, and inversely as the attractions of the centres of force at a unit of distance.*

This relation which is true for elliptic orbits, is general for all systems, and gives the means of comparing the masses of different systems. But it is necessary to observe a modification which Kepler's third law and this extension of it have to undergo to make them strictly true (as regards, at least, the unperturbed motions of the planets). The masses of the planets, though very small, yet bear definite relations to the sun, and instead of considering each planet as swayed by the sun's mass, we must regard each as swayed by the sum of its own mass and the sun's, supposed to be gathered at the sun's centre. Thus we must regard the planets as revolving around centres of different attractive energy; Jupiter round a centre equal in mass to Jupiter and the sun; Saturn round a centre equal in mass to Saturn and the sun, &c. Instead, then, of the ratio $\frac{(\textit{mean distance})^3}{(\textit{period})^2}$ being constant for the solar system, we find that this ratio for any given planet is proportional to the sun's mass added to that planet's. Extending the law to bodies travelling around different centres, it runs as follows:—

If a body of mass m revolves round a centre of mass M in time P, and at a mean distance D, and another body of mass m' revolves round another centre of mass M′ in time P′, and at a mean distance D′, then

$$\frac{D^3}{P^2(M+m)} = \frac{D'^3}{P'^2(M'+m')}$$

This law enables us at once to compare the sums of the masses when we know the mean distances and periods. For it may be written

$$\frac{M+m}{M'+m'} = \frac{D^3}{D'^3} \cdot \frac{P'^2}{P^2}$$

Also, where m and m' are both small, compared with M and M′ respectively, the law becomes simplified into

$$\frac{M}{M'} = \frac{D^3}{D'^3} \cdot \frac{P'^2}{P^2}$$

These laws suffice to enable us to deduce from the observed periods of the planets their true mean distances, velocities, &c., and from the observed period of the satellite of any planet, the ratio of the planet's mass to the sun's. The eccentricities of the planetary orbits are partly deduced from observation, and partly from the law of the equable description of areas. The inclinations of the orbits, and, of course, all elements relating to the planets' own globes, their dimensions, compression, inclination, rotation, and so on, are obtained by telescopic observation and measurement.

The following tables of elements are brought into one place for convenience of reference, and include many items of information referred to in the chapters on the several planets. The illustrative Plates numbered XXVII. and XXVIII. should be studied in combination with the table of planetary elements.

Stability of the Solar System.

We may conveniently add here to the laws of planetary motion presented above the two following theorems (enunciated by Lagrange, but first established by Laplace).

First, *If the mass of each planet be multiplied by the square of the eccentricity, and this product by the square root of the mean distance, the sum of the products thus formed will be invariable.*

Secondly, *If the mass of each planet be multiplied by the square of the tangent of the orbit's inclination to a fixed plane, and this product by the square root of the mean distance, the sum of the products thus formed will be invariable.*

These laws ensure the stability of the system. It is true that the whole eccentricity, if it could by any possibility fall on any one planet (except Jupiter or Saturn), would cause the planet's orbit to interfere with the orbits of other planets, or even, in the case of a small planet, to intersect the sun's globe. Yet the interchange of eccentricities can never lead to this result. In fact, the sum of the products $(\textit{mass}) \times (\textit{eccentricity})^2 \times (\textit{mean distance})^{\frac{1}{2}}$ for Jupiter and Saturn will always largely exceed the sum of all such products for the remaining planets.

The fixed plane from which the inclination is to be measured, in the second law, is nearly identical with the plane of Jupiter's orbit. Its inclination to the ecliptic is about 1° 35½′, and the longitude of the node (in 1850) was about 104° 21′. Comparing these values with the corresponding elements on next page, we see that the inclination of the planetary orbits would have a smaller mean value if estimated from the invariable plane than they had as estimated from the plane of the ecliptic.

CHAPTER VII.—*The Sun—Sun Spots—Rotation of the Sun—His Physical Constitution and Surroundings—Prominences—Corona—Zodiacal Light.*

The sun, the central and ruling body of the planetary system, and the source of light and heat to our earth and all the members of that system, is a globe about 852,900 miles in diameter. So far as observation extends, his figure is perfectly spherical, no difference having been observed between his polar and spherical diameters. It has been well remarked, indeed, by Sir G. Airy, that if any observer could by ordinary modes of measurement satisfy himself that a real difference existed between the diameters, that observer would have proved the inexactness of his own work; for the absence of any measurable compression comes out as the result of comparisons between thousands of observations of the sun's limbs made at Greenwich and other leading observatories. The volume of the sun exceeds the earth's 1,252,700 times. His mean density is almost exactly one-fourth of the earth's, and his mass exceeds hers about 316,000 times. Gravity at the surface of the sun exceeds terrestrial gravity about 27·1 times, so that a body dropped from rest near the sun's surface would fall through 436 feet in the first second, and have acquired a velocity of 872 feet per second.

Sun spots.

Viewed with the naked eye, the sun appears only as a luminous mass of intense and uniform brightness; but when examined with the telescope, his surface is frequently observed to be mottled over with a number of dark spots, of irregular and ill-defined forms, constantly varying in appearance, situation, and magnitude. These spots are occasionally of immense size, so as to be visible even without the aid of the telescope, and their number is frequently so great that they occupy a considerable portion of the sun's surface. Sir W. Herschel observed one in 1779, the diameter of which exceeded 50,000 miles, more than six times the diameter of the earth; and Scheiner affirms that he has seen no less than fifty on the sun's disk at once. Most of them have a deep black nucleus, surrounded by a fainter shade, or *umbra*, of which the inner part, nearest to the nucleus, is brighter than the exterior portion. The boundary between the nucleus and umbra is in general tolerably well defined; and beyond the umbra a stripe of light appears more vivid than the rest of the sun.

The discovery of the sun's spots has been attributed to Fabricius, Galileo, and Scheiner, and has been claimed for the English astronomer Harriot. Amidst these conflicting pretensions it is perhaps impossible to arrive at the truth; but the matter is of little importance; the discovery is one which followed inevitably that of the telescope, and an accidental priority of observation can hardly be considered as establishing any claim to merit.

Sun's rotation.

The solar spots furnish an extensive subject of curious speculation. They are, first, interesting on account of their establishing the fact of the rotation of the sun, and affording the means of determining its period. Let M, M′, M″, fig. 23, be the successive positions of a spot on the surface of the sun on different days. Then, correction being made for the earth's advance during these days, M, M′, M″ will represent the apparent path of the spot on the sun's disk. This path, as thus corrected, is in general an oval slightly differing from an eclipse; and it is found that all the spots observed at the same time describe similar and parallel curves. They also return to the same relative positions in the same time, and their period is about 27⅓ days.

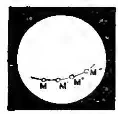

Fig. 23.

The paths described by the spots undergo very considerable changes, according to the season of the year at which they are observed. About the end of November and beginning of December they appear simply as straight lines, M*m*, M′*m*′, M″*m*″ (fig. 24), along which the spots move in

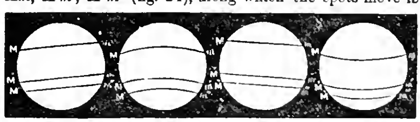

Fig. 24. Fig. 25. Fig. 26. Fig. 27

Diagrams showing motion of sun spots at different seasons.

the direction M*m*; that is, they enter on the eastern and disappear on the western edge of the sun's disk, and the points at which they disappear are more elevated, or nearer the north pole of the ecliptic than those at which they enter. After a certain time the lines M*m*, &c., begin to assume a curved appearance. During the winter and spring the convexity of the ovals is turned towards the north pole of the ecliptic; but their inclination, or rather the inclination of the straight lines joining their extreme points, to the plane of the ecliptic continues to diminish, and about the beginning of March disappears; so that the points at which they seem to enter and leave the sun's disk are equally elevated, as in fig. 25. From this time the curvature of the ovals diminishes; they become narrower and narrower till about the end of May or beginning of June, when they again appear under the form of straight lines (fig. 26): but their inclination to the ecliptic is now precisely in a contrary direction to what it had been six months before. After this they begin again to expand, and their convexity is now turned towards the south pole. Their inclinations also vary at the same time, and about the commencement of September they are seen as represented in fig. 27; the points at which they enter and disappear being again equally elevated. After this period the ovals begin to contract and become inclined to the ecliptic, and by the beginning of December they have exactly the same direction and inclination as they had the previous year.

These phenomena are renewed every year in the same order, and the same phases are always exhibited at corresponding seasons. Hence it is evident that they depend on a uniform and regular cause, which is common to all of them, since the orbits described by the various spots are exactly parallel, and subject in all respects to the same variations. The true explanation of the phenomena was early recognised by Galileo, who maintained that the spots belong to the surface of the sun, and that the sun uniformly revolves round an axis inclined to the axis of the ecliptic.

From four different combinations of equations, derived from eleven observations of the same spot, Delambre computed the following table of the elements of rotation:—

No.	Node.	Inclination.	Revolution.	Synodic Revol.
1	80° 45′ 7″	7° 19′ 17″	25 0h 17m	26d 4h 17m
2	79 21 35	7 12 37	...	...
3	80 33 40	7 16 33	...	...
4	79 47 55	7 29 4	...	...
Mean	80 7 4	7 19 23	Diurnal motion 14°·394	

With regard to observations of the sun's spots, for the purpose of determining the rotation, Delambre remarked that he attached little value to them,—first, because it is impossible to make them well; and secondly, because (as he erroneously supposed) they could only lead to results of little importance. He discussed a hundred different spots, each observed at least three times by Messier, and deduced thirty different determinations of the elements of rotation. The more he multiplied his calculations, the more certain he became of the impossibility of a good solution; of which, indeed, there is no other chance than in a compensation of errors, little probable on account of their enormous magnitudes. These discrepancies have been accounted for in recent times, chiefly through the labours of Mr Carrington. It had been suspected that the spots, besides partaking of the general motion of the solar globe, have also proper motions occasioned either by displacement or by a change of form. Carrington not only succeeded in proving that both these causes operate, but also in recognising systematic proper motions of the spots at rates depending on their solar latitude. It would not be possible to assign definitely the nature of such proper motions, simply because we do not know the normal rotation rate of the sun; and therefore we are compelled, in describing Carrington's results, to speak of varying rotation rates, although it can hardly be doubted that the sun's globe, as a whole, has a definite rate of rotation, and that all the seeming variations from this rate are due to proper motions of the spots. Adopting, however, the only available method of describing Carrington's results, the following table represents the various rotation rates for different solar latitudes in both hemispheres:—

Deg.	Sun's Rotation Period. d.	h.	m.	Rotation per Day
50 N. lat.	27	10	41	787
30	26	9	46	824
20	25	17	8	840
15	25	9	10	851
10	25	3	29	859
5	25	0	42	863
0 Equator	24	2	11	867
5 S. lat.	24	23	18	865
10	25	5	35	856
15	25	13	31	845
20	25	17	52	839
30	26	12	50	814
45	28	11	0	759

It is noteworthy that in each southern latitude the rotation is less than in the corresponding northern latitude, yet the difference is too small to admit of our attaching at present any considerable importance to this indication. Taking the mean between the results for the northern and southern hemispheres, Mr Carrington has deduced the following empiric formula for the rotation rates in different solar latitudes —

Let ξ be the angle through which a part of the sun in latitude λ rotates in one day; then

$$\xi = 14^\circ\, 25' - 165' \sin.^{\frac{7}{4}} \lambda$$

Spörer, who has made similar observations, deduces the law

$$\xi = 16^\circ{\cdot}8475 - 3^\circ{\cdot}3812\, (\sin.\lambda + 41^\circ\, 13')\,.$$

The following elements have been deduced from the results by Carrington and Spörer (for the year 1869):—

Elements.	Carrington.	Spörer.
Longitude of node of solar equator	73° 57′	74° 37′
Inclination of solar equator	7 15	6 57
Mean diurnal rotation	14 18	14 26 64
Mean rotation period.........	25d·38	25d·234

bridge, U.S., in March and April 1870. These views, though showing the spots as they have only been seen with the improved instruments of our day, will serve to illustrate the following account of the history of research into these objects better than pictures resembling the imperfect drawings made by the first observers.

Telescopic study of sun spots. The phenomena of the solar spots, as observed by Scheiner and Hevelius, may be summed up in the following particulars:—1. Every spot which has a nucleus, or comparatively dark part, has also an umbra, or fainter shade surrounding it. 2. The boundary between the nucleus and umbra is always distinct and well defined. 3. The increase of a spot is gradual, the breadth of the nucleus and umbra dilating at the same time. 4. In like manner the decrease of a spot is gradual, the breadth of the nucleus and umbra contracting at the same time. 5. The exterior boundary of the umbra never consists of sharp angles, but is always curvilinear, how irregular soever the outline of the nucleus may be. 6. The nucleus of a spot, whilst on the decrease, often changes its figure

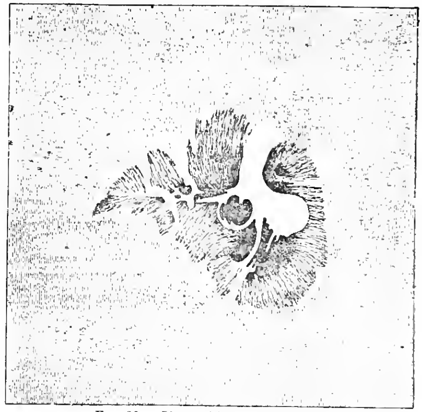

FIG. 31.—Phase of Spot, figs. 29, 30.

by the umbra encroaching irregularly upon it, insomuch that in a small space of time new encroachments are discernible, whereby the boundary between the nucleus and umbra is perpetually varying. 7. It often happens, by these encroachments, that the nucleus of a spot is divided into two or more nuclei. 8. The nuclei of the spots vanish sooner than the umbræ. 9. Small umbræ are often seen without nuclei. 10. An umbra of any considerable size is seldom seen without a nucleus in the middle of it. 11. When a spot which consisted of a nucleus and umbra is about to disappear, if it is not succeeded by a *facula* or spot brighter than the rest of the disk, the place where it was is soon after not distinguishable from the rest.

In the *Philosophical Transactions*, vol. lxiv. (1774), Dr Alexander Wilson, professor of astronomy at Glasgow, gave a dissertation on the nature of the solar spots, in which he mentioned the following appearances:—1. When the spot is about to disappear on the western edge of the sun's limb, the eastern part of the umbra first contracts, then vanishes, the nucleus and western part of the umbra remaining; then the nucleus gradually contracts and vanishes, while the western part only of the umbra remains. At last this disappears also; and if the spot remains long enough to become again visible, the eastern part of the umbra first becomes visible, then the nucleus; and when the spot approaches the middle of the disk, the nucleus appears environed by the umbra on all sides, as already mentioned. 2. When two spots lie very near to one another, the umbra is deficient on that side which lies next to the other spot; and this will be the case, though a large spot should be contiguous to one much smaller; the umbra of the large spot will be totally wanting on that side next the small one. If there are little spots on each side of the large one, the umbra does not totally vanish, but appears flattened or pressed in towards the nucleus on each side. When the little spots disappear, the umbra of the large one extends itself as usual. This circumstance, he observes, may sometimes prevent the disappearance of the umbra in the manner above mentioned; so that the western umbra may disappear before the nucleus if a small spot happens to break out on that side.

These observations led Dr Wilson to adopt the opinion, that the appearances of the spots are occasioned by real excavations in the solar globe. He supposed the sun to consist of a dark nucleus, covered only to a certain depth by a luminous matter, not fluid, through which openings are occasionally made by volcanic or other energies, permitting the solid nucleus of the sun to be seen; and that the umbra which surrounds the spot is occasioned by a partial admission of the light upon the shelving sides of the boundary opposite to the observer. It is evident that, in proportion as these excavations are seen obliquely, their apparent dimensions will be diminished; one of the edges will disappear as it approaches the sun's limb, or come more into view as it advances towards the middle of the disk; when the spot is about to leave the disk, the bottom of the excavation, or the nucleus seen through it, will first disappear, but a sort of faint or obscure spot will remain visible as long as the visual ray penetrates the cavity

Dr Wilson's theory was keenly combated by Lalande, who adduced several observations of his own, and some by Cassini, that could not be explained by means of it; and urged with reason that an hypothesis, founded on the uniformity of appearances which in reality are exceedingly variable, was entitled to little consideration. Lalande himself supposed the spots to be scoriæ which have settled or fixed themselves on the summits of the solar mountains; an opinion which he grounded on the circumstance that some large spots which had disappeared for several years were observed to form themselves again at the identical points at which they had vanished.

Sir William Herschel, with a view to ascertain more accurately the nature of the sun, made frequent observations upon it from the year 1779 to the year 1794. He imagined the dark spots on the sun to be mountains, which, considering the great attraction exerted by the sun upon bodies placed at its surface, and the slow revolution it has upon its axis, he thought might be more than 300 miles high, and yet stand very firmly. He says that in August 1792 he examined the sun with several powers from 90 to 500, when it evidently appeared that the dark spots are the opaque ground or body of the sun, and that the luminous part is an atmosphere, through which, when interrupted or broken, we obtain a view of the sun itself. Hence he concluded that the sun has a very extensive atmosphere, consisting of elastic fluids that are more or less lucid and transparent, and of which the lucid ones furnish us with light. This atmosphere, he thought, cannot be less than 1843 nor more than 2765 miles in height; and he supposed that the density of the luminous solar clouds needs not be much more than that of our aurora borealis, in order to produce the effects with which we are acquainted. The sun, then, if this hypothesis be admitted, "is similar to the other globes of the solar system with regard to its solidity, its atmosphere, its surface diversified with mountains and valleys, its rotation on its axis, and the fall of heavy bodies on its surface; it therefore appears to be a very eminent, large, and lucid planet, the primary one in our system, disseminating its light and heat to all the bodies with which it is connected."

Herschel supposed that there are two regions or strata of solar clouds; that the inferior stratum is opaque, and probably not unlike our own atmosphere, while the superior is the repository of light, which it darts forth in vast quantities in all directions. The inferior clouds act as a curtain to screen the body of the sun from the intense brilliancy and heat of the superior regions, and, by reflecting back nearly one-half of the rays which they receive from the luminous clouds, contribute also greatly to increase the quantity of light which the latter send forth into space, and thereby perform an important function in the economy of the solar system. The luminous clouds prevent us in general from seeing the solid nucleus of the sun; but in order to account for the spots, he supposes an empyreal elastic gas to be constantly forming at the surface, which, carried upwards by reason of its inferior density, forces its way through the planetary or lower clouds, and mixing itself with the gases which have their residence in the superior stratum, causes decomposition of the luminous matter, and gives rise to those appearances which he describes under the name of *corrugations*. Through the openings made by this accidental removal of the luminous clouds, the solid body of the sun becomes visible, which, not being lucid, gives the appearance of the dark spots or nuclei seen through the telescope. The length of time during which the spots continue visible renders it evident that the luminous matter of the sun cannot be of a liquid or gaseous nature; for, in either case, the vacuity made up by its accidental removal would instantly be filled up, and the uniformity of appearance invariably maintained.

Sun-spot period.

But, perhaps, the most important of all the discoveries which have been made respecting the sun spots, are those which relate to the variation of these objects in number, and in the amount of solar area which they cover. We owe the initiation of observations on these points to Schwabe of Dessau. They were commenced in the year 1826, and continued without intermission, except in one case, during the astronomer's illness, for forty-six years. Before many years had elapsed, Schwabe discovered that the spots wax and wane in frequency in a period of about eleven years. At the time of spot-minimum the sun remains often for several days not only clear of spots, but with a singular smoothness of aspect, even the minute mottlings ordinarily seen on his surface either passing away for a time or becoming less conspicuous than usual. From such an epoch there is a gradual return to the spotted condition, and usually in four or five years the maximum of spot-frequency is reached; then there is a more gradual reduction, until, in rather more than eleven years on the average, the minimum is reached. The table on page 787 indicates the facts actually observed by Schwabe between 1826 and 1868, supplemented by observations of a similar kind made at the Kew Observatory to the year 1871.

It will be seen that the law of variation is not uniformly periodic; the intervals between maximum and maximum are not strictly equal, and the maxima are neither equal nor similar.

The researches of M. De la Rue and his assistants Stewart and Loewy have indicated further laws of variation, apparently connecting the changes of spot-frequency with the movements of the planets Mercury, Venus, the earth, and Jupiter. According to their views the great eleven-year period would correspond with the periodic revolution of Jupiter. It is, however, noteworthy that Professor Wolf of Zurich estimates the spot period at 11·11 years,—a period differing too much from Jupiter's to accord with De la Rue's theory. And Carrington notes that, whereas certain epochs of spot-maxima accord with the passage by Jupiter of his perihelion, others accord almost as exactly with Jupiter's aphelion passage. Yet Wolf accepts the theory of planetary influence. "He finds," says Sir John Herschel, "that a perceptibly greater apparent activity prevails annually, on the average, in the months of September to January, than in the other months of the year; and, again, by projecting all the results in a continuous curve, he finds a series of small undulations succeeding each other at an average interval of 7·65 months, or 0·637 of a year. Now the periodic time of Venus, reduced to a fraction of a year, is 0·616,—a coincidence certainly near enough to warrant some considerable suspicion of a physical connection." A longer period, during which the spot-maxima would seem to vary, has been suspected by Wolf. It was suggested by Mr Proctor in 1865, and Prof. Loomis (of Yale College, U.S.) has since advocated the theory, that this period corresponds to the successive conjunctions of Saturn and Jupiter; but the connection is doubtful.

Year.	Days of Observation.	Days without Spots.	New Groups.

Connection of sun spots with terrestrial phenomena.

One of the most interesting results following Schwabe's great discovery was the recognition of an association between the sun-spot period and magnetic disturbances on the earth. Lamont of Munich had independently discovered, in 1850, that the mean daily range of the magnetic declination varies in a period of about ten years. Two years later, General Sabine and Professors Wolf and Gautier noted the coincidence of this period and that of the solar spots. Wolf afterwards proved that the true period of magnetic variation amounts to 11·11 years approximately. Some still regard the association between the sun-spot period and auroral phenomena as non-existent; but all doubt on the subject appears to be removed by the evidence adduced in two able papers by Professor Loomis (*American Journal of Science and Arts*, September 1870 and April 1873). In the same papers Professor Loomis indicates the evidence of association between the number of auroras observed each year, and the two orders of phenomena—solar spots and magnetic variations. He remarks that, "the auroral maximum generally occurs a little later than the magnetic maximum, the average difference amounting to one year; while the time of auroral minimum either coincides with the magnetic minimum or slightly precedes it, the average difference amounting to about half a year. On the whole," he proceeds, "there seems to be no room for question that the number of auroras seen in the middle latitudes of Europe and America exhibits a true periodicity, following very closely the magnetic periods, but not exactly copying them. In particular, we notice that during those periods in which the range of the magnetic declination was unusually small auroral exhibitions were extremely few in number and insignificant in respect of brilliancy. If now we inquire as to the probable connection between these three classes of phenomena, we cannot suppose that a small black spot on the sun exerts any direct influence on the earth's magnetism or electricity; but we must rather conclude that the black spot is a result of a disturbance of the sun's surface, which is accompanied by an emanation of some influence from the sun, which is almost instantly felt upon the earth, in an unusual disturbance of the earth's magnetism, and a flow of electricity, developing the auroral light in the upper regions of the earth's atmosphere. The appearances favour the idea that this emanation consists of a direct flow of electricity from the sun. If we maintain that light and heat are the result of vibrations of a rare ether which fills all space, the analogy between these agents and electricity would lead us to conclude that this agent also is the result of vibrations in the same medium, or at least that it is a force capable of being propagated through the ether with a velocity similar to that of light. While this influence is travelling through the void celestial spaces it develops no light; but as soon as it encounters the earth's atmosphere, which appears to extend to a height of about 500 miles, it develops light, and its movements are controlled by the earth's magnetic force, in a manner analogous to the influence of an artificial magnet upon a current of electricity circulating round it."

Spectroscopic analysis.

Among the most interesting discoveries in solar physics are those which have been effected by means of the spectroscopic analysis, not only as regards the constitution of the sun himself, but as to the nature of the solar spots and faculæ, as well as of the various objects which lie outside the sun's visible surface, and are only rendered discernible during the darkness of total solar eclipses.

The evidence of the spectroscope respecting the sun's constitution is too intimately associated with the history of spectroscopic analysis to be properly discussed at any length in this place. We propose, therefore, to present results, rather than to describe in detail the processes by which these results have been obtained, or the considerations on which must be based the interpretation of such results.

It has been shown, then, that the light of the sun comes from an orb glowing with intense *white* light,—that is, light of all refrangibilities. Hence the sun is either liquid or solid, or if vaporous, then so greatly compressed that, in fact, the condition of its vapours is unlike that of any gases with which we are familiar. But inasmuch as the rainbow-tinted streak constituting the solar spectrum is crossed by a multitude of dark lines, it is seen that the glowing mass of the sun is surrounded by a complex vapourous envelope at a lower temperature. Nevertheless we are not to suppose that the vapours constituting the solar atmosphere are in any sense cool. In fact, we find from the position of the dark lines of the solar spectrum, that the vapours of magnesium and sodium, of iron, copper, and other metals, exist in the true solar atmosphere, which

[1] These lines are from the records of the Kew Observatory.

implies an excessive intensity of heat. We know also, in another manner presently to be described, that the vapours of the solar atmosphere, although less intensely hot than the glowing mass of the sun, are yet so hot as to be brightly luminous.

The evidence respecting the constitution of the sun is based on the following coincidences between dark lines of the solar spectrum and bright lines in the spectra of various elements:—

	Lines coincident.		Lines coincident.
Hydrogen	4	Manganese	57
Sodium	9	Chromium	18
Barium	11	Cobalt	19
Calcium	75	Nickel	33
Magnesium	4 + (3?)	Zinc	2
Aluminium	2 (?)	Copper	7
Iron	450	Titanium	200

It must not be supposed either that no other terrestrial elements exist in the sun, or that no other coincidences are recognisable. The above list simply indicates the results obtained by Angström, and presented in the latest available announcement on the subject. With each improvement in spectroscopic appliances fresh coincidences are determined. Moreover, it is certain that many elements existing in the sun may for ever escape notice, simply because their vapours in the solar atmosphere may be either insufficient in quantity, or too low down to produce any recognisable effect.

Mitscherlich and others have lately shown that where one or two lines of a many-lined spectrum are recognised and others wanting, the evidence for the existence of the corresponding element in the sun may yet be regarded as sufficient, because under certain conditions only one or two lines of a spectrum show themselves.

The evidence given by the spectroscope respecting the solar spots confirms the theory that these are due to the existence of masses of relatively cool vapours at a lower level, and therefore relatively more compressed than the vapours elsewhere existing in the solar atmosphere. For the spectrum of the umbra of a spot differs chiefly from the spectrum of the solar photosphere in the greater strength and breadth of some of the dark lines.

Phenomena of eclipses.

We pass on to the phenomena witnessed during total solar eclipses. These are the red prominences and sierra, the inner corona, and the outer or radiated corona. Some add to these "Baily's beads" and like phenomena, of no real interest or importance whatever.

Prominences.

The red prominences were first seen during the solar eclipse of July 8, 1842. During the eclipse of July 28, 1851, it was shown incontestably that they belong to the sun, since the moon was seen to traverse them, hiding those on the east and revealing those on the west. Some still maintained that the prominences are lunar or terrestrial phenomena, on the ground that observers might have been deceived. But this doubt was finally set at rest by the photographic records which De la Rue and Secchi obtained of the total solar eclipse of June 18, 1860.

It was not, however, until the eclipse of August 1868—sometimes known as the great Indian eclipse—that the real nature of these wonderful objects was ascertained. Spectroscopic analysis was applied successfully to the investigation of the prominences by Colonel Tennant, Captain Herschel, and MM. Janssen and Rayet. The spectrum was found to consist of bright lines, indicating that the coloured prominences are masses of glowing vapour. All the observers agreed that among the bright lines those of hydrogen were present; and one yellow line was mistakenly ascribed to sodium.

But Janssen on the day following the eclipse applied a new method of research, the principle of which had been definitely indicated several months before by Mr Huggins. (See Report of the Council of the Astronomical Society, in the *Monthly Notices* for February 1868.) This method depends on the fact that prismatic dispersion reduces the brilliancy of a continuous spectrum, but only throws apart the lines of a bright-line spectrum. Accordingly, by using a spectroscope of sufficient dispersive power, and directing it (with suitable telescopic adjuncts) towards a part of the solar limb on which a prominence exists, the light of our atmosphere, which under ordinary conditions obliterates the prominences from view, may be sufficiently dispersed to leave the bright lines of the prominence spectrum discernible (*one at a time*). By noting the length of a bright line so seen, the extent of the prominence in the particular section viewed could be determined; and by combining such determinations, the shape of the prominence could be ascertained. Hence it was that Janssen, speaking of his observations on the day following the great eclipse, said, "I have enjoyed to-day a continuous eclipse."

It happened, curiously enough, that Mr Lockyer, in England, had succeeded in applying the method, not indeed so early as Janssen, but before the news of Janssen's success had reached Europe.

Before long, however, Mr Huggins, the first to enunciate the principle of the new method, showed how it could be improved upon in such sort that the whole of a prominence could be seen at once. Since then many observers have studied the prominences without the aid of an eclipse,—the most successful being Zöllner, Secchi, Lockyer, Respighi, and (above all) Professor Young, of Dartmouth College, New Hampshire.

The following remarks respecting the prominences have been derived from a paper by Respighi:—

"In the circumpolar solar regions great prominences are not formed, but only small and short-lived jets. In the spot zone the great prominences are seen, the equatorial, like the polar zones, being regions of relatively small activity. Where faculæ are present prominences are usually seen, but they are not identical with faculæ. Over spots the jets are seen, but they are not high. There is a great difference in the duration of prominences. Some develop and disappear in a few minutes; others remain visible for several days. They originate, generally, in rectilinear jets, either vertical or oblique, very bright and well defined. These rise to a great height, often to a height of at least 80,000 miles, and occasionally to more than twice that; then, bending back, fall again upon the sun like the jets of our fountains. Then they spread into figures resembling gigantic trees, more or less rich in branches. In general, the highest parts are the regions of the most remarkable transformations."

Sierra

Before passing to the more systematic researches made by Secchi, a few words must be said about the sierra.

It had been observed, even before the prominences were noticed, that there exists a border of a red colour around the solar disk, which can be recognised on the eastern side just after totality has commenced, and on the western side just before totality ceases. Late observations abundantly confirmed the discovery, and after the eclipse of 1860 it had been definitely admitted by all who had sufficiently examined the evidence, that a continuous red envelope surrounds the sun to a depth of three or four thousand miles. This envelope was commonly called the sierra; but recently the name chromosphere (which purists correct into chromatosphere) has been given to it.

The new method of observation, as might be expected, shows the sierra spectrum as successfully as that of the prominences, which must be regarded as extensions of the sierra.

Secchi makes the following remarks on the sierra and prominences:—

"The sierra presents four aspects: (1), smooth, with a defined outline; (2), smooth, with no definite outline; (3), fringed with filaments; and (4), irregularly fringed with small flames.

"The prominences may be divided into three orders—heaps, jets, and plumes. The heaped prominences need no special description. The jets are those to which alone Respighi's description is applicable. Their luminosity is intense, insomuch that they can be seen through the light clouds into which the sierra, breaks up. Their spectrum indicates the presence of many elements besides hydrogen. When they have reached a certain height they cease to grow, and become transformed into exceedingly bright masses, which eventually separate into fleecy clouds. The jet prominences last but a short time, rarely an hour, frequently but a few minutes, and they are only to be seen in the neighbourhood of the spots. Wherever the jet prominences are seen, there also are faculæ. The plume prominences are distinguished from the jets in not being characterised by any signs of an eruptive origin. They often extend to an enormous height, they last longer than the jets, though subject to rapid changes of figure, and lastly, they are distributed indifferently over the sun's surface. It would seem that in jets a part of the photosphere is lifted up, whereas in the case of plumes only the sierra is disturbed."

The theoretical inquiries of Zöllner, confirmed by his own and Respighi's observations, show the probability that the jet prominences are true phenomena of eruption. And more recently, Professor Young has witnessed what must be regarded as in all probability a veritable solar eruption, during which matter was propelled to a height of upwards of 200,000 miles above the sun's surface. The matter whose motion was actually observed was glowing hydrogen; but it should be noticed that it does not necessarily follow that the matter erupted was hydrogen. The outrush may have carried along with it portions of hydrogen which had before been quiescent in the solar atmosphere.

Corona. The solar corona comes next to be considered.

It had long been known that around the black disc of the moon in total solar eclipses a halo or glory of light is seen, rather bright close by the sun, and fading away at first somewhat quickly, afterwards gradually, into the darkness of the surrounding sky. The records of some total eclipses described also radiations in this coronal glory, extending in many cases to a great distance from the sun.

Various theories were propounded in explanation of the solar corona. According to one view, it was a mere terrestrial phenomenon, due to the passage of the solar rays through our own atmosphere. Others ascribed it to the effects produced by a lunar atmosphere. The theory that it is due to diffraction was also advanced. But the generality of astronomers, especially in recent times, regarded the corona as a true solar appendage.

Space will not permit us to enter at length on the discussion of the various theories just mentioned, or on the description of the various observations which appeared to give support to one theory or another. Nor can we present in full the interesting history of the observations made since 1869, when first the spectroscope was applied to this interesting phenomenon, and real evidence as to its nature and structure began to be obtained. We must be content with the brief statement of the salient points of the recent observations.

During the solar eclipse of August 1869 the American astronomers, Young and Harkness, discovered that the spectrum of the corona is discontinuous (or that at least a portion of its light gives a discontinuous spectrum). Certainly one, and probably three bright lines appeared in the spectrum as they saw it, though the faintness of two of the three lines raised some doubt on the question whether they belonged to the corona. During the eclipse of December 1870, Young renewed his observations successfully, and other observers succeeded in seeing the bright-line spectrum of the corona. Young thus sums up the results of his own and other observations:—"There is," he said, "surrounding the sun, beyond any further reasonable doubt, a mass of self-luminous gaseous matter, whose spectrum is characterised by the green line 1474 Kirchhoff. The precise extent of this it is hardly possible to consider as determined, but it must be many times the thickness of the red hydrogen portion of the chromatosphere, perhaps on an average 8′ or 10′, with occasional horns of twice that height. It is not at all unlikely that it may even turn out to have no upper limit, but to extend from the sun indefinitely into space."

It was during this eclipse that for the first time photography gave convincing evidence respecting the corona. Mr Brothers at Sicily, and Mr Willard (an American photographer) in Spain, obtained views which, though differing in extent, accorded so well in those parts which were common to both, as to leave no doubt that the corona is a solar and not a terrestrial phenomenon. A singular V-shaped gap, common to both the photographs, and seen also by several telescopists, attracted particular attention, and was regarded by the late Sir John Herschel as in itself demonstrative of the fact that the corona is a solar appendage.

It was not, however, until the solar eclipse of December 1871 that the evidence on this point became so convincing as to satisfy even those who had most strenuously maintained the theory that the corona is merely a phenomenon of our own atmosphere. The spectroscopic and the photographic evidence were alike important. Janssen, with the spectroscope, succeeded in recognising, besides the bright lines already seen, others less bright, but manifestly belonging to the corona. He also perceived a faint continuous spectrum, crossed by dark lines, and therefore presumably due to reflected solar light, which, since our upper air near the sun's place, in total eclipse, is demonstrably not illuminated by sunlight, can have come only from matter in the true corona, such as meteoric flights, vapour clouds, or the like, capable of reflecting the light of the sun. The photographers met with equally decisive success. Lord Lindsay's photographer, Mr Davis, obtained a series of five pictures of the corona at successive stages of the totality, two of which were excellent and the remainder good. All these agreed perfectly in all respects, save only in the extent of the visible corona (depending, of course, on the conditions of illumination). It was demonstrated, therefore, that the features of the corona do not change during the progress of an eclipse at any given station; hence the corona cannot be a phenomenon depending on the passage of light-rays athwart inequalities of the moon's limb. For whether we regard such rays as illuminating our own atmosphere or matter between the earth and the moon, the illumination would necessarily vary markedly, as the motions of the moon shifted the inequalities of her limb progressively athwart the light-rays. Again, Col. Tennant obtained a series of six photographs (five of which were very good), agreeing perfectly (always excepting differences of extent) with those obtained by Lord Lindsay's photographer. Now Col. Tennant's station was at Dodabetta, near the highest peak of the Neilgherries, more than 10,000 feet above the sea level, while Mr Davis was stationed at Baicull, close to the sea-shore, and hundreds of miles from Tennant's station. The agreement of two series taken under such diverse circumstances, proves to demonstration that the photographers were not dealing with the illumination of matter in the upper regions of our atmosphere, no matter under what circumstances illuminated. Later, indeed, it was found that photographs taken at Java gave precisely the same features, so that, as Col. Tennant remarks in the latest communication on the subject (*Monthly Notices of the Astronomical Society* for June 1873), no one now supposes the corona to be other than a solar phenomenon.

The accompanying picture (fig. 32), carefully copied from the first of Col. Tennant's series of photographs, will afford an idea of the nature of the corona's structure, though only an inadequate one, since photography can present only a portion of an object like the corona, whose light is for the most part extremely delicate.

FIG. 32.—Solar Corona.

Another very curious phenomenon connected with the sun is the faint nebulous aurora which accompanies him, known by the name of the *Zodiacal Light.* This phenomenon was first observed by Kepler, who described its appearance with sufficient accuracy, and supposed it to be the atmosphere of the sun. Dominic Cassini, however, to whom its discovery has been generally but erroneously attributed, was the first who observed it attentively, and gave it the name which it now bears. It is visible immediately before sunrise, or after sunset, in the place where the sun is about to appear, or where he has just quitted the horizon. It has a flat lenticular form, and is placed obliquely on the horizon, the apex extending to a great distance in the heavens. Its direction is in general nearly in the plane of the sun's equator, and for this reason it is scarcely visible in our latitudes, excepting at particular seasons, when that plane is nearly perpendicular to the horizon. When its inclination is great, it is either concealed altogether under the horizon, or it rises so little above it that its splendour is effaced by the atmosphere of the earth. The most favourable time for observing it is about the beginning of March, or towards the vernal equinox. The line of the equinoxes is then situated in the horizon, and the arc of the ecliptic is more elevated than the equator by an angle of $23\frac{1}{2}°$; so that the solar equator, which is slightly inclined to the ecliptic, approaches nearer to the perpendicular to the horizon, and the pyramid of the zodiacal light is consequently directed to a point nearer the zenith than at any other season of the year.

Numerous opinions have been entertained respecting the nature and cause of this singular phenomenon. Cassini thought it might be occasioned by the confused light of an innumerable multitude of little planets circulating round the sun, in the same manner as the Milky Way owes its appearance to the light of agglomerated myriads of stars. Its resemblance to the tails of comets has been noticed by Cassini and others. Mairan, following Kepler, ascribed it to the atmosphere of the sun. This hypothesis was generally adopted until Laplace showed it to be untenable, because no atmosphere could rotate with the sun if extending beyond the distance where centrifugal force is balanced by gravity, and this distance lies far within the observed range of the zodiacal light.

The general opinion respecting the zodiacal light at the present day is, that it forms the outer part of the solar corona, so that if the light of the sun could be for a time obliterated without rendering his appendages invisible, we should see the corona as shown in the preceding figure, merging gradually into the faint glow of the zodiacal light. It must not be understood, however, that this theory in any sense implies a continuity of substance between the zodiacal light and the corona, any more than what has been discovered respecting the corona implies that the corona is a true solar atmosphere. All that is to be understood is, that (1) the inner corona, (2) the outer radiated corona, and (3) the zodiacal light, form part of the series of appendages surrounding the orb of the sun.

It is to be noted, indeed, that the true atmosphere of the sun appears to underlie even the sierra. It had been noted by Secchi in 1869, that on the very limb of the sun the solar spectrum becomes continuous; and he inferred that there must exist an atmosphere (relatively very shallow), consisting of the vapours which occasion the dark lines of the solar spectrum, and that the brightness of the lines of these vapours corresponding very nearly to the brightness of the ordinary solar spectrum for the parts of the sun very near to the edge, the dark lines of the latter spectrum are as it were cancelled, and so a continuous spectrum is produced. This view was shown during the eclipse of December 1870 to be perfectly correct; for Prof Young, directing his analysing spectroscope to the part of the sun's limb which was to disappear last, found that at the instant when totality commenced, the solar spectrum was suddenly replaced by a spectrum consisting of thousands of bright lines, that being precisely the kind of spectrum which Secchi's theory required. This observation was successfully renewed during the eclipse of December 1871, and again during the *annular* eclipse of June 1872. On the latter occasion the remarkable circumstance was noted, that while the bright-line spectrum was only visible for a second or two on the eastern limb (just before the formation of the ring), it was visible for six or seven seconds on the western limb (just after the annulus was broken).

Young's atmosphere.

CHAPTER VIII.—*The Inferior Planets Mercury and Venus.*

Mercury is a small body, but emits a very bright white light, though he is seldom to be seen, always keeping near the sun.

Mercury.

Mercury is about 3060 English miles in diameter, and his mean distance from the sun about 35 millions of miles. On account of his smallness and brilliancy, it is extremely difficult to find any spot on his disk so distinctly marked as to afford the means of determining his rotation. An attentive observation of the variations of the phases of Mercury led Schröter to infer that the planet revolves about its axis in a period of 24 hours 5 min. 30 sec. M. Harding discovered in 1801 an obscure streak on the southern hemisphere of the planet, the observations of which, together with those of a spot discovered by Schröter, gave the same period of rotation. Schröter states that Mercury's form is spherical, exhibiting no sensible compression; that his equator is very considerably inclined to his orbit, and the differences of his days and seasons must consequently be very great; and that there are mountains on his surface which cast very long shadows, and of which the height bears a greater proportion to the diameter of the planet than those of the Earth, the Moon, or even of Venus. The height of Chimborazo is $\frac{1}{1017}$ of the radius of the earth; one of the mountains in the moon has been estimated at $\frac{1}{214}$ of her radius; the highest in Venus at $\frac{1}{144}$; and one in Mercury at $\frac{1}{126}$. But recent observations render it exceedingly doubtful how far Schröter's observations can be trusted. There are no observations to prove decisively whether Mercury is surrounded by an atmosphere.

Venus. Venus, the most beautiful object in the heavens, is about 7510 English miles in diameter, and is placed at the distance of 66 millions of miles from the sun. Although the oscillations of this planet are considerably greater than those of Mercury, and she is seldom invisible, yet on account of the uniform brilliancy of her disk, it is extremely difficult to ascertain the period of her rotation. Dominic Cassini, after having long fruitlessly attempted to discover any object on her surface so well defined as to enable him to follow its motions, at length, in 1667, perceived a bright spot, distant from the southern horn a little more than a fourth part of the diameter of the disk, and near the eastern edge. By continuing his observations of this spot, Cassini concluded the rotation of Venus to be performed in about 23 hours; but he does not seem to have considered this conclusion as deserving of much confidence. In the year 1726 Bianchini, an Italian astronomer, made a number of similar observations for the same purpose, from which he inferred that the rotation of the planet is performed in 24 days 8 hours.' The younger Cassini has shown, however, that the observations of Bianchini, as well as those of his father, could be explained by a rotation of 23 hours and 21 or 22 min. whereas the rotation of 24 days 8 hours cannot be reconciled with the appearances observed by the elder Cassini. The determination of Cassini was regarded by astronomers as the more probable of the two, particularly as Bianchini was not able to make his observations in a connected manner, because a neighbouring building intercepted his view of the planet, and obliged him to transport his telescope to a different situation. The question of the rotation of Venus was again attacked by Schröter, who found it to be performed in 23 hours 21 min. 19 sec. Each of the three observers found the inclination of the axis of rotation to the axis of the ecliptic to be about 75°. Much doubt, however, still exists with respect to the value of this element which De Vico sets at little more than 50°.

Schröter's observations of this planet were principally directed to a mountain situated near the southern horn. The line which joins the extremities of the horns is always a diameter; and the horns of the crescent of a perfect sphere ought to be sharp and pointed. Schröter remarked that this was not always the case with regard to the horns of Mercury and Venus. The northern horn of the latter always preserved the pointed form, but the southern occasionally appeared rounded or obtuse,—a circumstance which indicated that the shadow of a mountain covered the part; but beyond the horn he remarked a luminous point, which he supposed to be the summit of another mountain, illuminated by the sun after he had ceased to be visible to the rest of that hemisphere. Now, in order that the horn of the crescent may appear obtuse in consequence of the shadow of a mountain falling upon it, and another mountain may present a luminous point, the two mountains must be at the same time both at the edge of the disk and on the line separating the dark from the enlightened part of the planet. But this position cannot be of long continuance. Rotation will cause the bright point to rise into the enlightened part, or sink into the dark hemisphere, and in either case the mountain will cease to be visible. If, however, the rotation is completed in 23 hours 21 min., the mountain will appear 39 min. sooner than it did on the previous day. Hence it is possible to obtain several consecutive observations, from which an approximate value of the period may be found; and this being once obtained, it may be rendered still more exact by observations separated from each other by a longer interval. Thus Schröter found that an interval of 20 days 11 hours 15 min. between two appearances of the mountain being divided by 23 hours 21 min. gave 21·04 revolutions; and that intervals of 121 days 14 hours 25 min., 142 days 1 hour 40 min., 155 days 18 hours 11 min., divided each by 23 hours 21 min., gave 125·01, 146·02, 160·09 revolutions respectively. All these comparisons prove that the revolution of 23 hours 21 min. is somewhat too short. They ought to have given 21, 125, 146, and 160 revolutions exactly, supposing the observations to have been perfectly accurate. On dividing the intervals by 21, 125, 146, and 160 respectively, the quotients will be each the time of a revolution very nearly; and by taking a mean of the whole, the most probable result at least will be obtained. In this manner Schröter found the period of rotation already stated, namely, 23 hours 21 min. 19 sec.

Since the time of rotation of Mercury and Venus is nearly equal to that of the earth, the compression of these planets at the poles, which results from the centrifugal force, ought also to be nearly in the same proportion. But at the distance of the earth the compression must be imperceptible even in the case of Venus; for, supposing it to amount to $\frac{1}{300}$, the difference between the radius of her poles and that of her equator would only amount to a tenth of a second as seen from the earth.

Phenomena of transits. During the transits of Venus over the sun's disk in 1761 and 1769 a sort of penumbral light was observed round the planet by several astronomers, which was occasioned, without doubt, by the refractive powers of her atmosphere. Wargentin remarked that the limb of Venus which had gone off the sun showed itself with a faint light during almost the whole time of emersion. Bergman, who observed the transit of 1761 at Upsal, says that at the ingress the part which had not come upon the sun was visible, though dark, and was surrounded by a crescent of faint light; but this appearance was much more remarkable at the egress: for as soon as any part of the planet had disengaged itself from the sun's disk, that part was visible with a like crescent, but brighter. As more of the planet's disk disengaged itself from that of the sun, the part of the crescent farthest from the sun grew fainter, and vanished, until at last only the horns could be seen. The total immersion and emersion were not instantaneous; but as two drops of water, when about to separate, form a ligament between them, so there was a dark shade stretched out between Venus and the sun; and when this ligament broke, the planet seemed to have got about an eighth part of her diameter from the limb of the sun. The numerous accounts of the two transits which have been published abound with analogous observations, indicating the existence of an atmosphere of considerable height and density. During the transit of 1874 these appearances were so satisfactorily seen, that no doubt can remain as to their reality. Schröter calculated that the horizontal refraction of the atmosphere of Venus must amount to 30′ 34″, differing little from that of the terrestrial atmosphere. A twilight which he perceived on the cusps afforded him the data from which he deduced this conclusion, on which, however, very little reliance can be placed.

The atmosphere of Venus has been analysed with the spectroscope by Vogel, and the existence of aqueous vapour is regarded as demonstrated. On the occasion of the late transit (1874) Tacchini made spectroscopic observations, which seem more satisfactorily to establish the fact that there is water on Venus, than Vogel's observations.

Cassini and Montaigne imagined that they had observed a satellite accompanying Venus; but this appears to have been an optical illusion arising from the strong light of the planet reflected back from the convex surface of the eye upon the eye-glass of the telescope, and thence reflected a second time back to the eye. During the transits of Venus in 1761 and 1769, and in the late transit of 1874, no trace of a satellite was seen; and there can be now no doubt whatever that Venus is without a satellite.

CHAPTER IX.—*The Earth regarded as a Planet—Figure and Mass of the Earth—Precession of the Equinoxes—The Shape and Position of the Earth's Orbit—Distance from the Sun—Transit Observations.*

The earth is the third member of the solar system in order of distance from the sun. From what has been already shown, in determining the relative position of the earth and the celestial bodies seen in our skies, we know that the earth is a globe, rotating on her axis once in a day, and circling around the sun in an orbit of great extent once in a year. In the present chapter we propose to present the results of more exact inquiries into the figure and motions of the earth.

Figure of the earth. It has been found by numerous and accurate experiments, that the lengths of arcs of 1° on the same meridian are greater in proportion as we advance nearer the pole. Hence, on account of the similarity of the isosceles triangles of which these arcs form the bases, their sides, or the terrestrial radii, must also be longer, and consequently the convexity of the earth is less towards the poles than at the equator. The surface of the earth is extremely irregular, even independently of the inequalities occasioned by mountains and cavities; yet it has been discovered that the meridional curves differ almost insensibly from ellipses; whence it is concluded that the figure of the earth is an ellipsoid of revolution about its shortest axis. In comparing the results of the various measurements which have been made with the formulæ belonging to the dimensions of such a body, this conclusion has been fully verified; and the lengths of the arcs, the ellipticity, the distance of the pole from the equator, and, in short, all the elements of the spheroid, have been determined.

An arc of the meridian in India was measured by Colonel Lambton in the early part of this century. But its value has been much increased by Colonel Everest's extension of the arc. The arc of Lambton, extending from Punnæ (lat. 8° 9′ 35″) to Damargida (lat. 18° 3′ 15″), was measured after the model of the English trigonometrical survey. From Damargida, where Lambton's arc terminated, another was measured by Colonel Everest to Kaliana (lat. 29° 30′ 48″), a space of 797 miles, covering an arc of 11° 27′ 33″, the latest geodetical improvements being introduced. The whole extent of Lambton's and Colonel Everest's operations includes a continuous arc of 21° 21′ (1477 miles). The work was rivalled in extent by a vast operation executed in Russia and other northern countries of Europe, by which an arc of 25° 20′, extending from the banks of the Danube to the shores of the Arctic Sea, near the North Cape, was measured under the general superintendence and direction of W. Struve.

The arcs of India and of Russia include a space from lat. 8° to lat. 71°, with the exception of only about sixteen degrees, and are unquestionably the most important which exist for the determination of the earth's figure. When to them we add the French arc of 12° 22′ in a medium latitude, it will scarcely be necessary to take into account any other, at least for the northern hemisphere.

The following brief details of the Russian arc are taken from M. Struve's report of 1852:—

The southern extremity of the Russo-Scandinavian arc is Ismail on the Danube (lat. 45° 20′), the northern extremity is Fuglenaes, on the island of Qualoe, in Finnmarken (lat. 70° 40′). The interval from Tornea to Fuglenaes (4° 49′) was measured by Swedish and Norwegian engineers; all the remainder by those of Russia, and, in particular, by M. Von Tenner, who, with M. Struve, from 1816 directed the whole operation.

The calculation of the figure of the earth from the completed Russian arc indicates an ellipticity somewhat greater than that generally received. The results obtained by Colonel Everest, on the other hand, by comparing his arc with those of Europe, give generally small ellipticities, that is, under $\frac{1}{300}$. The French and Indian arcs, for instance, give $\frac{1}{316}$. The determinations by means of the pendulum are somewhat larger. The extensive observations of Colonel Sabine and Captain Foster concur in giving an ellipticity of $\frac{1}{289}$, but the French experiments by Duperrey and Freycinet lead to a result considerably greater. The discrepancy between the geodetical and pendulum results may, of course, be a real one depending on local variations of density. The astronomical determination from the lunar inequalities, which might be expected to concur with the results of the pendulum, gives $\frac{1}{306}$ as a mean. Captain A. R. Clark, R.E., combining all the results obtained up to the year 1860, arrived at conclusions thus stated by Sir J. Herschel:—"The earth is not exactly an ellipsoid of revolution. The equator itself is slightly elliptic, the longer and shorter diameters being respectively 41,852,864, and 41,843,096 feet. The ellipticity of the equatorial circumference is therefore $\frac{1}{4283}$, and the excess of its longer over its shorter diameter about two miles. The vertices of the longer diameter are situated in longitude 14° 23′ E and 194° 23′ E. of Greenwich, and of its shorter in 104° 23′ E. and 284° 23′ E. The polar axis of the earth is 41,707,796 feet in length, and consequently the most elliptic meridian (that of longitude 14° 23′ and 194° 23′) has for its ellipticity $\frac{1}{287 \cdot 5}$, and the least (that of longitude 104° 23′ and 284° 23′) an ellipticity of $\frac{1}{308 \cdot 5}$."

General Schubert, using a method which Sir J. Herschel justly regards as less trustworthy, "makes the ellipticity of the equator $\frac{1}{8885}$, and places the vertices of the longer axis 26° 41′ to the eastward of Captain Clark's. His polar axis, as deduced from each of the three great meridian arcs, the Russian, Indian, and French respectively, is 41,711,000 feet, 41,712,534 feet, and 41,697,496 feet, the mean of which, giving to each a weight proportional to the length of the arc from which it is deduced, is 41,708,710 feet."

Earth's mass and density. The figure and volume of the earth being thus determined, we require only to ascertain its mean density in order to know its mass. But this problem has not been solved, probably cannot be solved, with any very near approach to exactness. Various methods have been employed, the mere description of which suffices to show the difficulty and uncertainty of the subject.

Mountain experiments. The deviation of the plumb line from the vertical in the neighbourhood of a mountain had been pointed out by Newton[1] as a direct method of dealing with the problem of

[1] *De Mundi Systemate*, § 22. Newton, in a very remarkable passage of the Third Book of the *Principia* (Prop. X.), conjectures that "the quantity of matter in the earth may be five or six times greater than if the whole were composed of water."

determining the earth's density. Bouguer had the merit of pointing out the form in which the experiment might be made, and of making the trial, though in a rude and insufficient manner, in the Peruvian Andes in 1738. Maskelyne proposed to the Royal Society in 1772 to repeat the observation on some British mountain. Skiddaw and the Yorkshire Hills were first thought of, but finally Schihallion in Perthshire was preferred. The distance between the two stations, obtained with Ramsden's 9-inch theodolite, was 4364·4 feet, which in the latitude of Schihallion corresponds to 42″·94 of latitude. The observed difference of latitude by 337 observations with Sisson's 10-feet zenith sector was 54″·6. The excess, or 11″·6, is the double attraction of the hill drawing the plumb-line towards itself at the two stations. The sine of this angle, or $\frac{1}{17804}$, represents the *actual* ratio between the double attraction of the hill and the attraction of the earth. But by the computation of the attraction which the hill ought to exert, from its figure, as determined by Maskelyne's gauges, were its density the same as that of the globe generally, this ratio should amount to $\frac{1}{9933}$, which can only be accounted for by assuming the earth to be denser on the average than the hill of Schihallion in the proportion of 17,804 to 9933. A careful lithological survey of the hill enabled Professor Playfair to deduce the probable mean specific gravity of the globe to be between 4·56 and 4·87.

Cavendish experiment.

A second method was devised by the Rev. Mr Michell, but first put in practice by Mr Cavendish in 1797–8. It consisted in measuring the force of gravitation between two spheres of such small size that they could be moved by the hand nearer to or farther from one another. To provide a balance so delicate as to measure the almost inappreciable attraction of such small bodies, Michell imagined the *balance of torsion.* His apparatus came into the hands, first of Wollaston, then of Cavendish, who made the experiment. He used a very light rod of deal, six feet long, suspended by a fine silver or copper wire, forty inches long, within a wooden case to defend it from currents of air. At each end of the lever was hung a ball of lead, two inches in diameter, and by a simple contrivance a pair of leaden spheres, weighing together 348 pounds, could be brought simultaneously into the neighbourhood of the balls (but outside the case), on opposite sides, so that their attractions might concur to swing the suspended lever out of the position of repose which it had previously taken up, under the action of the slight twisting force of the silver wire. A new position of rest was thus established, the small balls being pulled as much one way by the attraction of the spheres as they were urged in the opposite direction by the torsion of the wire. The position of repose being observed from a distance by a telescope (to avoid disturbance from the heat of the observer's body), the great spheres were then changed in position so as to act upon the opposite sides of the small balls, from what they formerly did. The deflection and new stable position would be as much on the other side of the zero, and the arc described would be an accurate measure of the double deflection. The force of torsion for one degree of deflection is known by the time of oscillation of the lever and balls when free, and as the forces are exactly as the angles, the force corresponding to any displacement becomes known. Cavendish found the joint attraction of the small balls and large spheres to be about $\frac{1}{4300}$ of a grain, their centres being 8·85 inches apart, and he thence computed the density of the earth to be 5·48 times that of water. The experiment has been repeated since by Reich of Freiberg and Baily of London. The former obtained 5·44, the latter 5·66 for the earth's specific gravity,—this last result being worthy of much confidence, from the extraordinary care taken to avoid errors and to obtain independent values of the quantities sought.

Pendulum experiments.

A third method of determining the earth's density depends on the fact that a pendulum suspended at a considerable height above the earth would swing more slowly than at the surface, while if it be at the summit of a mountain, though it will still swing more slowly, the attraction of the mountain will slightly accelerate the rate of swing. Carlini and Plana, by observations made on this plan, have deduced 4·950 for the mean density of the earth. The objection to this method, as well as to the Schihallion experiment, resides in our uncertainty as to the actual mean density of any given mountain mass. If the experiment could be carried out by pendulum observations made at the base and on the summit of a conical or conoidal mass, of some known material and of great height, the true density of the earth could thence be very accurately determined.

A similar objection applies to the converse of the third method described above. If a pendulum be suspended at the bottom of a deep mine, of known figure, and existing in a region whose geological structure is well known, the change of rate gives a means of calculating the density of the earth, since it obviously depends on the calculable difference of attraction due to increased proximity to the earth's centre (reducing the attraction), and to the absence of counter-attracting matter where the mine is dug out (which in effect increases the attraction). In the Harton colliery, experiments were carried out by Mr Dunkin on this plan in accordance with arrangements devised by the astronomer royal. It was found that gravity was increased by $\frac{1}{19190}$th part at the lower station, 1260 feet below the mouth of the mine, where the upper station was placed. Hence Airy found that, on taking into account the configuration of the mine and the structure of the surrounding region, a density of 6·565 resulted. Very little reliance can be placed, however, on results obtained by this method.

It may be fairly assumed that the earth's mean density amounts to about 5·6 times the density of water, combining which with the known dimensions of the earth, we find that the earth's weight in tons may be roundly expressed by the number 6,000,000,000,000,000,000,000.

Position of earth's axis.

We have next to inquire into the rotation of the earth about its axis, and especially into the position of that axis. In Chapter I. we considered the axis as fixed in position; or, seeing that the earth circles around the sun, we regarded the axis as moving always parallel to itself, while the earth traversed her path in the plane of the ecliptic. But we must now take into account variations in its position with reference to the ecliptic. In this inquiry we should naturally take the ecliptic as our plane of reference, if we were assured that the position of the plane of the ecliptic is constant,—in other words, that the sun's path in the heavens undergoes no change. This is, in fact, so nearly the case that the ecliptic forms a suitable reference circle for the fixed stars—far more suitable for example than the equator itself. The star's *latitude*, that is, its distance from the ecliptic measured on the arc of a great circle through the poles of the ecliptic, is very nearly constant, while the *longitude*, or the distance between the point ♈ and the point where the great circle through the star cuts the ecliptic, undergoes, as will presently appear, a variation nearly uniform, and nearly the same for every star; whereas the declination and right ascension of stars are undergoing variations which are neither alike for different stars nor uniform for any star. Yet the place of the ecliptic on the heavens is not absolutely constant. The ecliptic, in fact, is inclined about 1½° to the invariable plane mentioned at the end of Chapter VI., and this inclination is undergoing a slow process of change, while the nodes of the ecliptic on it are slowly shifting. A result of this is that the obliquity of the ecliptic is changing, for the mean inclination of the earth's axis to the invariable plane does not change, so that the mean inclination of this axis to the ecliptic must necessarily change. At present the obliquity of the ecliptic—that is, the inclination of the equator to the ecliptic—is diminishing; and this process, which has been going on for many centuries, will continue for a long time yet to come, after which the obliquity will increase, the total range on either side of the mean value amounting to about 3°. The various observations and traditions by which the progressive diminution of the obliquity is confirmed have been collected by Bailly. The following table contains those which appear to be the best authenticated, as well as the results of some more recent observations, from which the present value of the obliquity and the rate of its diminution may be deduced:—

Change of obliquity of ecliptic.

Year.	Name of Observer	Obliquity.		
Before Christ.		°	′	″
1100	Tcheou-Kong	23	54	3
200	Eratosthenes, confirmed by Hipparchus and Ptolemy	23	51	15
160	The Chinese	23	45	52
After Christ.				
827	Arabians at Baghdad	23	33	52
880	Albategni	23	35	40
1150	Almansor	23	33	30
1278	The Chinese	23	32	12
1437	Ulugh Begh	23	31	58
1490	Walther	23	29	47
1590	Tycho	23	29	52
1646	Riccioli	23	30	20
1660	Hevelius	23	29	10
1672	Cassini	23	29	00
1690	Flamsteed	23	28	48
1703	Bianchini	22	28	35
1736	Condamine	23	28	24
1743	Cassini de Thury	23	28	26
1750	Lacaille	23	28	19
1755	Bradley	23	28	15
1756	T. Mayer	23	28	16
1769	Maskelyne	23	28	10
1780	Cassini	23	27	54
1800	Maskelyne	23	27	56·6
	Piazzi	23	27	56·3
	Delambre	23	27	57
1813	Pond	23	27	48·66
1815	Bessel	23	27	47·46
1816	Brinkley	23	27	49 21
1825	Pearson	23	27	44 01

Although the comparison of these observations with one another gives very discordant results relatively to the law according to which the obliquity varies, their totality places the fact of its progressive diminution beyond all manner of doubt. It amounts to about $45\frac{1}{2}''$ per century at present, and may be regarded as uniform for many centuries to come.

Precession of the equinoxes.

The longitudes of the stars, as has already been mentioned, are measured on the ecliptic from the vernal equinox; and therefore, if the line of the equinoxes, which is the same as the line of the nodes, is invariable, the longitude of any star will always be the same, whatever interval of time may elapse between two observations of that longitude. But on comparing the actual state of the heavens with the observations recorded by ancient astronomers, it is perceived that the longitudes of all the stars are considerably increased. The phenomenon is to be explained by attributing to the equinoctial points a retrograde motion from east to west, in consequence of which the sun, whose motion is direct, arrives at them sooner than if they remained at rest; and therefore the equinoxes, and spring, autumn, and the other seasons, happen before the sun has completed an entire circuit. On this account the motion has been denominated the *Precession of the Equinoxes.* As this motion is extremely slow, its exact amount can be discovered only by a comparison of observations separated from each other by long intervals of time. The comparison of modern observations with those of Hipparchus gives as its annual amount $50\frac{2}{3}''$. The mean result of the observations of Tycho, compared with those of Lacaille, gives $50\frac{1}{3}''$. On comparing modern observations with one another, we find 50″·06. Delambre, in his solar tables, supposes the annual precession to be equal to 50″·1. According to this estimate the equinoctial points go backwards at the rate of 1° in 71·6 years nearly, and therefore will make a complete revolution of the heavens in about 25,868 years.

The diminution of the obliquity of the ecliptic arises from the displacement of the ecliptic itself; the precession of the equinoxes is, on the contrary, occasioned by the continual displacement of the plane of the terrestrial equator. This displacement results from the combined action of the sun and moon (for the influence of the planets amounts only to a fraction of a second, and is consequently scarcely sensible) on the mass of protuberant matter accumulated about the earth's equator, or the matter which forms the excess of the terrestrial spheroid above its inscribed sphere. The attracting force of the sun and moon on this shell of matter may be resolved into two; one parallel to the plane of the equator, the other perpendicular to it. The tendency of this last force is to diminish the angle which the plane of the equator makes with that of the ecliptic; and if the earth had no motion of rotation, it would soon cause the two planes to coincide. In consequence, however, of the rotatory motion of the earth, the inclination of the two planes remains constant; but the effect produced by the action of the force in question is, that the plane of the equator is constantly shifting its place, in such a manner that the line of the equinoxes advances in the direction of the diurnal motion, or contrary to the order of the signs, its pole having a slow angular motion about the pole of the ecliptic.

If the sun and moon moved in the plane of the equator, there would evidently be no precession; and the effect of their action in producing it varies with their distance from that plane. Twice a year, therefore, the effect of the sun in causing precession is nothing; and twice a year, namely, at the solstices, it is a maximum. On this account the obliquity of the ecliptic is subject to a semi-annual variation; for the sun's force, which tends to produce a change in the obliquity, is variable, while the diurnal motion of the earth, which prevents the change from taking place, is constant. Hence the plane of the equator is subject to an irregular motion, which is technically called the *Solar Nutation.* The existence of the solar nutation is, however, only a deduction from theory, for its amount is too small to be perceptible by observation; but a similar effect of the moon's action is sufficiently appreciable, and was, in fact, discovered by Bradley before theory had indicated its existence. Its period, however, is different, and depends on the time of the revolution of the moon's nodes, which is performed in 18 years and about 7 months. During this time the intersection of the lunar orbit with the ecliptic has receded through a complete circumference, and the inequality of the moon's action will consequently, in the same time, have passed through all its different degrees. Bradley observed that the declinations of the stars continued to augment during nine years, that they diminished during the nine years following, and that the greatest change of declination amounted to 18″. He remarked further, that this motion was connected with an

Nutation.

irregularity of the precession of the equinoxes, which followed exactly the same period; whence he concluded that the motion of the poles of the equator, occasioned by this vibration of its plane, was not confined to the solstitial colure. A series of observations on stars differently situated proved that all the phenomena could be explained on the hypothesis that the pole of the equator describes in 18 years a small circle of 18″ diameter, contrary to the order of the signs; or that the axis of the earth, following the circumference of this circle, describes the surface of a cone, the axis of which forms with its side an angle of 9″. This apparent vibratory motion is denominated the *Nutation of the Earth's Axis.*

Bradley remarked that the effects of the nutation would be represented still more accurately by supposing the curve described by the pole of the equator about its mean place to be, not a circle, but an ellipse, the transverse and conjugate axes being 18″ and 16″ respectively. This is also confirmed by theory, from which Laplace calculated the semi-axes of the ellipse at 9″·63 and 7″·17. The semi-transverse axis of the ellipse described by the pole in virtue of the sun's action alone does not exceed half a second, and is therefore scarcely appreciable. The sensible part of the nutation follows exactly the period of the revolution of the nodes of the moon. By 603 observations of Polaris, made at Dorpat between 1822 and 1838, M. Peters has determined the semi-axis major of the ellipse to be 9″·2361, and gives, for his definitive result, 9″ 2231.

We must draw a distinction then, between the *mean* and the *true* or *apparent* obliquity of the ecliptic. The mean obliquity is the obliquity calculated for any particular date on the supposition that there is no nutation, while the true obliquity is that quantity increased or diminished by the nutation. The progressive diminution of the mean obliquity and the nutation of the earth's axis are inequalities distinguished from each other, not only by their being derived from different and distinct causes, but still more by the very great difference of time required for their full development.

Change of eccentricity and perihelion of earth's orbit.

The path in which the earth at present travels around the sun is indicated in the elements (p. 782). Plate XXVII. also shows the varying rate at which the earth moves owing to the eccentricity of her orbit. It will be seen also from that plate, and more precisely from the table of elements, that the perihelion of the orbit lies near the place of the winter solstice, so that, in fact, about ten days after midwinter of the northern hemisphere the earth is at her nearest to the sun. An important difference thus exists between the seasons of the two hemispheres. In the northern we have the sun farthest from us a few days after midsummer, while at the corresponding season in winter the sun is at his nearest. So far, then, as the sun's distance is concerned, the seasons are rendered more moderate for the northern hemisphere by the effects of the earth's eccentricity. Nor is the difference on this account by any means inconsiderable. The sun in aphelion is farther from us than in perihelion in the proportion of about 61 to 59, and the earth receives more heat in the proportion of about 31 to 29, or roughly, about $\frac{1}{15}$th more heat in aphelion than in perihelion. There is also a difference due to the varying rate of the earth's real (that is, of the sun's apparent) motion. In winter the earth moves more rapidly than in summer, really as 61 to 59, but the apparent change of the sun's rate of motion along the ecliptic is as 31 to 29, because the increased rate is magnified by the earth's greater proximity. Hence the interval from the autumnal to the vernal equinox is shorter than the interval from the vernal to the autumnal equinox. This also is shown by Plate XXVII., where the number of divisions marking the earth's daily journey is seen to be greater in the summer half than in the winter half of the orbit. Thus the winter cold is less enduring than the summer heat. In the southern hemisphere all these relations are reversed. The summer heat is rendered more intense by the greater proximity of the sun, the winter cold is intensified by his increased distance. The summer heat is less enduring than the winter cold. We have in the north a relatively short but moderate winter (so far as the sun's proximity can moderate winter cold); and a long but also moderate summer; in the southern hemisphere they have a short and intensely hot summer, a long but also intense winter. The presence of a great expanse of sea in the southern hemisphere partially tends to moderate the seasonal changes; but we see in the wider extension of the antarctic snows the effect of the long and cold winter and the short summer. We have, however, referred to these considerations less on account of their intrinsic importance, than to show how the eccentricity of the earth when near its maximum value, and when the perihelion was differently situated from its present position, may have caused the condition of the two terrestrial hemispheres to differ from that now existing. The present value of the eccentricity is nearer the minimum than the maximum value, though the perihelion is at present so placed as to produce almost the maximum possible difference between the two hemispheres, with the present degree of eccentricity. It must not be supposed that the eccentricity, in obedience to the law relating to planetary eccentricities (Chapter VI.), oscillates between the absolute maximum and the absolute minimum, the perihelion shifting continuously forwards. On the contrary, the successive maxima and minima are very unequal, and are attained after very unequal intervals; while the perihelion, apart from short periods of regression, and though always progressing on the whole in any considerable period, yet progresses at very unequal rates in different periods. This will be seen from the following table, presenting the eccentricity as calculated for different epochs from 1,100,000 years before our present era till now, chiefly by Mr James Croll, but partly from Leverrier and Stone:—

Years B C	Eccentricity of Earth's Orbit.	Longitude of Perihelion.
1,100,000	0·0303	54° 12′
1,050,000	0 0326	4 8

While the shape of the earth's orbit and the position of its centre (whose longitude = long. of perih. + 180°) thus undergo continual alteration, her mean distance from the sun remains appreciably constant. This we know from the length of the year, which certainly has not changed ten seconds in length since the time of the Chaldean determination of that element.

Determination of sun's distance. There are various ways of determining the sun's distance from the earth in terms of the earth's semidiameter. The distance of a planet from the sun may likewise be obtained if we can find the means of measuring its distance from the earth at any epoch, for the geocentric positions of the sun and the planet being known from the theory of their motions, the radius vector of the orbit, or planet's distance from the sun at that epoch, may be found by a simple trigonometrical computation. To determine the distance of a planet from the earth, it might seem only necessary to determine its horizontal parallax; but in general the parallaxes of the planets are quantities by far too small to be directly observed. That of Mars, however, becomes very appreciable in particular circumstances, that is to say, when Mars is in opposition with the sun, and at the same time near the perihelion of his orbit. Thus, in the year 1751, on the 6th of October, that planet, being near his opposition, was observed at the same instant of time by Lacaille at the Cape of Good Hope, and by Wargentin at Stockholm; and the horizontal parallax deduced from the two observations, was found to amount to 24″·6, corresponding to a solar parallax of 9″·4.

Parallax of Mars. This method requires that observations should be made from opposite sides of the earth; but Flamsteed long ago pointed out that the distance of Mars might be determined by observing how much the planet's place is shifted by the diurnal rotation of the earth. Both methods have been employed very successfully in modern times. Stone, of Greenwich, by combining the two methods, discussing observations of Mars at the opposition of 1862,—made (1), at Greenwich, (2), at Greenwich and Cape Town, and (3), at Greenwich and Williamstown,—deduced a solar parallax of 8″·943. Winnecke, from the discussion of the same opposition as observed at Poulkowa and Cape Town, deduced the solar parallax 8″·964. Professor Newcomb of Washington, U.S., deduced the value 8″·855.

Transits of Venus. A more accurate method of determining the sun's distance, and thence the dimensions of the planetary orbits, is afforded, though rarely, by the transits of Venus over the sun's disk. When Venus is at her inferior conjunction, and at the same time very near either node, her body will be projected on the disk of the sun; and through the effect of her proper motion, combined with that of the earth, she will appear as a dark spot passing over the disk, and describing a chord which will be seen under different aspects by spectators placed at different points on the earth, because, by reason of the parallax, they refer the planet to different points on the solar disk. The position of the spectator not only occasions a difference in the apparent path described by the planet, but has also a very sensible influence on the duration of the transit, in consequence of which the parallaxes both of Venus and the sun can be determined with great exactness. In order to illustrate this, let E (fig. 33) represent the earth, V Venus, and S the sun. An observer placed at E, near the north pole of

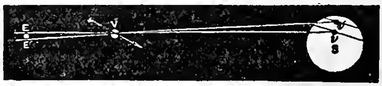

FIG. 33.—Diagram illustrating Transit of Venus.

the earth, would see Venus projected on the sun's disk at v, and she would appear to describe the line lvm. An observer placed at E′, near the south pole, would see the planet at v', and she would appear to describe the chord $l'v'm'$. This is a necessary result of the difference of the parallaxes of Venus and the sun; and as the chords lv, $l'v'$ differ in length according as they are more or less remote from the centre of the disk, the duration of the transit will be longer or shorter according to the situation of the observer and the geocentric latitude of the planet. If by reason of the relative parallax the time of a transit is longer than the true time in one hemisphere, it will be shorter in the other; and hence the difference of the times (which may be observed with great accuracy) at places having very different latitudes may serve to determine the relative parallax, or the difference between the parallax of Venus and that of the sun. But the parallaxes are reciprocally proportional to the distances; and the ratio of the distances being known, therefore the ratio of the parallaxes is also known; and having thus the ratio and the difference of the two parallaxes, it is easy to compute the separate amount of each.

This particular application of the transits of Venus to the determination of the sun's distance was first pointed out by Dr Halley, when he announced the transit of 1761. The transit of Venus in 1769 was observed in many different parts of the world. The result of the whole of the observations led to the conclusion, that the parallax of the sun is included within the limits 8″·5 and 8″·7. The mean 8″·6 was adopted by Delambre and Lalande; and later the value 8″·5776 was deduced by Encke from a careful re-examination of all the observations made in 1761 and 1769. But several methods have been since applied to the determination of the solar parallax, with results which appear to agree in indicating a larger value for the parallax, or in other words, a smaller value for the sun's distance, than had been deduced from the transits of 1761 and 1769.

Parallactic inequality. One of these depends on the moon's motions, and was first indicated by Laplace towards the close of the last century. Since the moon's distance from the earth, though small compared with the sun's, bears yet a measurable ratio thereto, it follows that there is not a perfect symmetry between the perturbations produced by the sun when the moon is passing from third to first quarter, and from first to third. The effect of this circumstance is recognisable in the lunar motions, which are affected by a minute variation arising from this cause, and called the *Parallactic Inequality*. It amounts at the maximum to about 2′; and as it depends on the proportion of the sun's distance to the moon's known distance, its amount supplies a means of determining the solar parallax. In 1854 Hansen announced, in a letter addressed to the astronomer royal, that this method, applied to his new tables of the lunar motions, gives a parallax of 8″·9159.

A second method depends on the fact, that the earth in reality revolves, in the course of a lunar month, around the common centre of gravity of her own globe and the moon's. The diameter of the orbit thus circuited by the earth (in the same sense, at least, as the moon may be said to circuit in her monthly orbit) amounts to about 6000 miles, and by the radius of this small orbit the earth is sometimes in advance of and sometimes behind her mean position in heliocentric longitude. The sun's geocentric longitude is affected to precisely the same degree as the earth's heliocentric longitude; and by determining the actual amount of the sun's displacement, we can ascertain what angle the mean diameter of the earth's monthly orbit subtends at the sun. Leverrier, by the careful study of a great number of observations of the sun made at the principal observatories in Europe, came to the conclusion that the solar parallax is 8″·95. But recently Mr Stone of Greenwich detected a numerical error in Leverrier's computations, and when this is corrected, the value 8″·91 results. Prof. Newcomb of Washington has by the same method deduced the value 8″·84.

Velocity of light.

Another method, depending on terrestrial measurements of the velocity of light, need not be here described, as the principles involved are mainly optical, and belong to the subject of LIGHT. Of course the comparison between the velocity of light measured without reference to extra-terrestrial bodies, and the velocity inferred from the time of the passage of light over given celestial distances, supplies at once the means of testing the accepted measures of these distances. Fizeau, by a measurement of the velocity of light depending on the rapid rotation of toothed wheels, has deduced a solar parallax falling even somewhat short of that obtained by Delambre from the transit of 1769. But Fizeau's method is not susceptible of great exactness. Foucault, by a much more effective method (the principle of which is due to Wheatstone), depending on the use of revolving mirrors, deduced the value 8″·942.

Deduced solar parallax.

We have seen that observations of Mars have given the values 8″·943 in Stone's hands, 8″·964 in Winnecke's, and 8″·855 in Newcomb's. By combining, according to their various importance, the values indicated above, the astronomer royal and Leverrier deduced the probable mean value 8″·94. Unfortunately, Leverrier's own estimate had not been corrected when this value was adopted, and 8″·92 may be considered as in all probability nearer the truth. But for the present 8″·94 may be adopted for convenience, as it has been used in the recalculation of the dimensions of the solar system by nearly all writers on astronomy in Europe and America. It is the value which has been used in the table of Elements at p. 782. Mr Stone, after discussing the observations made in 1769, with special reference to the effects of the peculiarity at the internal contacts of Venus, described in Chapter VIII., *supra*, has arrived at the conclusion, that the value 8″·9 more correctly represents the observations of 1769 than Delambre's 8″·6, or Encke's 8″·5776. But little value can be attached to this result, seeing that the correction for the interval of time between real contact and apparent contact comes out from the equations themselves which are made use of to determine the parallax, and this correction 17ˢ is constant, whereas the observed time difference in 1769 was not only far from constant, but in every instance far exceeded 17ˢ. One or two English astronomers still attach weight to Mr Stone's investigation, but Continental and American astronomers are unanimous in discarding it.

Much interest attaches to the late transit of 1874, now known to have been successfully observed at a sufficient number of stations to ensure success. At most of the stations the whole transit was observed by Halley's method. At the English stations in the northern hemisphere another method called Delisle's was employed. This method depends on the observation and eventual comparison of the absolute times of ingress or egress, where these phenomena are considerably accelerated or retarded by the effects of parallax. Photography has also been applied, as well as direct micrometrical measurement, to determine the planet's distance from the sun's centre at different epochs.

Owing to certain mistakes made with reference to the relative values of the two methods of observation, for the transits of 1874 and 1882, it was long thought that Delisle's only could be applied; and it was stated positively that Halley's method fails totally in 1874. But fortunately the mistake was discovered in good time, and in the summer of 1873, the leading astronomers of England urged the desirability of applying Halley's method. At the time of writing (April, 1875), the reports from the principal stations, though promising excellent results, afford no means of determining what changes will have to be made in our estimate of the sun's distance. The first rough analysis of some of the observations gives 8″·88 for the solar parallax. Another transit of Venus will occur on December 6, 1882; after which Venus will not again transit the sun until June 8, 2004, and June 6, 2012. The beginning of the transit of 1882, the whole transit of 2004, and the end of the transit of 2012, will be visible in England.

CHAPTER X.—*The Moon—Her Phases, Parallax, Magnitude, Motions, and Probable Physical Conditions.*

The different appearances or phases of the moon were probably the first celestial phenomena observed with any degree of attention. They have been described in general terms in Chapter IV., but must now be more particularly considered. The following definitions may conveniently be given in this place. When the moon passes the meridian at the same time with the sun, she is said to be in *Conjunction*. The two points of her orbit in which she is situated when in opposition and conjunction are called the *Syzygies;* those which are 90° distant from the sun are called the *Quadratures;* and the intermediate points between the syzygies and quadratures are called the *Octants.*

A slight attention to the lunar phases during a single revolution will be sufficient to prove that they are occasioned by the reflection of the sun's light from the opaque spherical surface of the moon. This fact, which was recognised in the earliest ages, will be made obvious by the help of a diagram. If the moon is an opaque body, we can only see that portion of her enlightened side which is towards the earth. Therefore, when she arrives at that point of her orbit M_1 (fig. 34) where she is in conjunction with the sun S, her dark half is towards the earth, and she disappears, as at 1, fig. 35, there being no light on that half to render it visible. When she comes to her first octant, at M_2, or has gone an eighth part of her orbit from her conjunction, a quarter of her enlightened side is towards the earth, and she appears horned, as at 2. When she has gone a quarter of her orbit from her conjunction, to M_3, she shows us one-half of her enlightened side, as at 3, and we say she is a quarter old. At M_4, she is in her second octant, and by showing us more of her enlightened side she appears gibbous, as at 4. At M_5, her whole enlightened side is towards the earth, and therefore she appears round, as at 5, when we say it is full moon. In her third octant, at M_6, part of her dark side being towards the earth, she again appears gibbous, and is on the decrease, as at 6. At M_7, we just see one-half of her enlightened side, and she appears as a semicircle, as at 7. At M_8, when she is in her fourth octant, we only see a quarter of her enlightened side, and she appears horned, as at 8. And as

Lunar phases explained.

M_1, having completed her course from the sun to the sun again, she disappears, and we say it is new moon.

The moon's absolute distance from the earth is obtained by means of her parallax, which on account of her proximity

FIG. 34.—Diagram illustrating the Phases of the Moon.

is very considerable. On comparing her parallaxes observed at different times, they are found to differ considerably in value. These differences in the value of the parallax arise from the variations of the moon's distance from the earth. But it is also observed to differ sensibly at different points of the earth's surface, even at

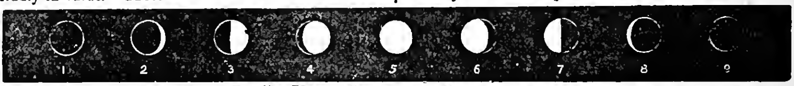

FIG. 35.—Diagram illustrating the Phaser of the Moon.

the same instant of time, on account of the spheroidal figure of the earth. Hence it is necessary, in speaking of the horizontal parallax, to specify the place of the observation.

Constant of parallax. Since the parallax of the moon is subject to incessant variation, it is necessary to assume a certain mean value, about which the true and apparent values may be conceived to oscillate. This is called the constant of parallax. If we abstract all the inequalities of the lunar orbit, and suppose the moon to be at her mean distance and mean place, the constant of parallax will be the angle under which a given semidiameter of the earth is seen by a spectator at the moon in such circumstances. But, for convenience, the constant of parallax is understood to be $= \frac{\text{earth's equat. rad.}}{\text{moon's mean dist.}}$, which, see Chapter IV, is in reality = sine of the mean horizontal parallax.

The best modern observations assign 57′ 2″·7 as the value of the lunar mean equatorial horizontal parallax, corresponding to a distance of 238,818 miles. The mean equatorial parallax being 57′ 2″·7, its double is 1° 54′ 5″·4, which expresses the angle subtended by the diameter of the earth at the distance of the moon. The angle subtended by the moon at the same distance is 31′ 5″·1; whence the diameter of the moon is to that of the earth as 31′ 5″·1 is to 1° 54′ 5″·4, or as 3 to 11 nearly. The accurate expression of the above ratio is 1 : 0·27251; hence the true diameter of the moon is 0·2725 diameters of the terrestrial equator. The surface of the moon is consequently $(0{\cdot}02725)^2 = 0{\cdot}0742 = \frac{1}{13\frac{1}{471}}$ of that of the earth, and its volume $(0{\cdot}2725)^3 = 0{\cdot}0202 = \frac{1}{49\frac{1}{441}}$ or, in round numbers, $\frac{2}{99}$ths of the volume of the earth. For other elements, see table of Lunar Elements, p. 782.

The *Ascending Node* of the lunar orbit is that point of the ecliptic through which the moon passes when she rises above the ecliptic towards the north pole; it is distinguished by the character ☊. The *Descending Node*, ☋, is the opposite point of the ecliptic, through which she passes when she descends below that plane towards the south. The position of the nodes is not fixed in the heavens. They move in a retrograde direction, or contrary to the order of the signs; and their motion is so rapid that its effects become very apparent after one or two revolutions.

The mean retrograde motion of the nodes is found, by the comparison of observations made at distant epochs, to amounts to 19° 21′ 18″·3 in a mean solar year, and the time in which they make a tropical revolution is consequently 6793·391 mean solar days. The inclination of the lunar orbit is observed to vary between 5° 3′ and 5° 13′. The mean inclination may be taken at 5° 8′.

The inclination of the lunar orbit to the plane of the terrestrial equator occasions considerable differences in the intervals between the moon's rising or setting on successive days, and gives rise to the phenomenon of the *Harvest Moon*. Harvest moon. As the daily motion of the moon is about 13° from west to east, it follows that if she moved in a plane parallel to the equator, she would rise 50 minutes later every successive evening. For the sake of explanation, we may here suppose the moon to move in the plane of the ecliptic. Now, the time in which a given arc of the ecliptic rises above the horizon depends on its inclination to the horizon. In our latitudes the inclination of the ecliptic at different points to the horizon varies so much, that at the first point of Aries an arc of 13° becomes visible in the short space of 17 minutes, while at the 23d of Leo the same arc will only rise above the horizon in 1 hour and 17 minutes. Hence, when the moon is near the first point of Aries, the difference of the times of her rising on two successive evenings will be only about 17 minutes; and as this happens in the course of every revolution, she will rise for two or three nights every month at nearly the same hour. But the rising of the moon is a phenomenon which attracts no attention, excepting about the time when she is full, that is, when she rises at sunset. In this case she is in opposition to the sun, and consequently, if she is in Aries, the sun must be in Libra, which happens during the autumnal months. At this season of the year, therefore, the moon, when near the full, rises for some evenings at nearly the same hour. This circumstance affords important advantages to the husbandman, on which account the phenomenon attracts particular attention.

It is obvious that, as this phenomenon is occasioned by the oblique position of the lunar orbit with regard to the equator, the effect will be greater than what has just been described if the plane of that orbit makes a greater angle with the equator than the plane of the ecliptic does. But we have seen that the plane of the moon's orbit is inclined to the ecliptic in an angle exceeding 5°; consequently, when her ascending node is in Aries, the angle which her orbit makes with the horizon will be 5° less than that which the ecliptic makes with the horizon, and the difference of time between her risings on two successive evenings will be less than 17 minutes, which would have been the time had her orbit coincided with the ecliptic. On the contrary, when the descending node comes to Aries, the angle which her orbit makes with the horizon will be greater by 5°, and consequently the difference of the times of her successive risings will be greater than if she moved in the plane of the ecliptic. If when the full moon is in Pisces or Aries the ascending node of her orbit is also in one of those signs, the difference of the times of her rising will not exceed 1 hour and 40 minutes during a whole week; but when her nodes are differently situated, the difference in the time of her rising in the same signs may amount to 3½ hours in the space of a week. In the former case the harvest moons are the most beneficial, in the latter the least beneficial to the husbandman. All the variations in the intervals between the consecutive risings or settings take place within the period in which the line of the nodes makes a complete revolution.

Lunar theory

The moon's orbit at any moment is an ellipse, having the earth at one of the foci; but this orbit is continually changing in form and position, the eccentricity alternately increasing and decreasing between the limits 0·066 and 0·044, and the perihelion sometimes advancing and sometimes retrograding, but on the whole advancing at an average rate of 40⅔° per annum, so as to complete a sidereal revolution in 3232·575 mean solar days. See also table of Lunar Elements. These changes, like those which affect the inclination of the orbit and the position of the nodes, are due to the perturbing influence of the sun on the moon's motions relatively to the earth. The consideration of these perturbations, whether as affecting the figure and position of the moon's orbit, or her motions in that orbit, constitutes what is called the *Lunar Theory*. The following are the chief peculiarities of the lunar movements :—

Equation of moon's centre.

In the first place, the moon's motion differs from uniform motion around the earth as centre, because the moon's orbit is elliptic, so that an equation of the centre corresponding to that already described in dealing with the sun's motion, but greater in amount, has to be applied to the mean motion.

Annual equation.

Secondly, the sun lying constantly far outside the moon's orbit relatively to the earth, his influence on the whole must tend to diminish the earth's influence. It is true that when the moon is in quadrature the sun's attraction tends to draw her towards the earth; but it is manifest that this influence is small compared with the action of the sun in drawing the moon from the earth when she is in conjunction with him, and in drawing the earth from the moon when she is in opposition. The balance of effects during a single lunation must correspond to a diminution of the earth's influence, or in other words, to an increase in the moon's period. Now, if the earth and moon, or their common centre of gravity, were always at the same distance from the sun, this action of his would be uniform all the year round. But as he is nearer in perihelion than in aphelion, he exerts a greater influence in the former than in the latter position; in other words, the lunar month in winter (when the sun is near perihelion) is lengthened to a greater degree by the sun's perturbing action than in summer (when the sun is in aphelion). Accordingly, on the whole, the moon's motion in longitude is less in winter than in summer. She lags behind her mean place more and more throughout the whole time that the sun is at a distance exceeding his mean distance; she is therefore at her maximum displacement, behind her mean place, near the time that the sun is at his mean distance after perihelion passage; while she is at her maximum displacement, in advance of her mean place, when the sun is at his mean distance after aphelion passage. The greatest amount by which, so far as this cause is considered, she gets in advance of or behind her mean place, is about 11′ 12″; and this displacement, because of its period, is called the *Annual Equation*.

The variation.

Since the sun acts to diminish the earth's influence when the moon is in syzygies, and to increase that influence when the moon is in quadratures, the motion of the moon is retarded in the former case and accelerated in the latter; and at the octants there is neither acceleration nor retardation. Hence arises an inequality called the *Variation*. It was discovered by Tycho Brahe, who found that the moon's place, calculated from her mean motion, the equation of the centre, and the evection, does not always agree with her true place, and that the variations are greatest in the octants, or when the line of the apsides makes an angle of 45° with that of the syzygies and quadratures. Having observed the moon at different points of her orbit, he found that this correction has no dependence on the position of the apsides, but only on the moon's elongation from the sun. Its maximum value is additive in the octants which come immediately *after* the syzygies, and subtractive in the octants which precede the syzygies. It vanishes altogether in the syzygies and quadratures, and on this account was not perceived by the ancient astronomers, who only observed the sun in those positions. Its maximum value is 35′ 42″.

The evection.

The next inequality to be mentioned is the largest of all, except, of course, the equation of the centre. It is called the *evection*, and was discovered by Hipparchus, but Ptolemy first recognised the law of its effects. These are to diminish the equation of the centre when the line of the apsides lies in syzygy, and to augment it when the same line lies in quadratures. Thus, supposing the apsides to lie in syzygy, and that it is sought to compute the moon's true longitude about seven days after she has left the perigee, by adding the equation of the centre to the mean anomaly, the resulting longitude will be found to be above 80′ less than that which is given by observation. But if the line of the apsides lies in quadratures, the place of the moon at about the same distance, that is, 90° from the perigee, computed in the same manner, will be found to be before the observed place by above 80′; that is, the computed will be *greater* than the observed longitude by more than 80′. The maximum value of the evection is 1° 20′ 29″·9. It is occasioned by the sun's action in modifying the form of the lunar orbit, and so causing the equation of the centre to vary in amount.

Secular inequalities.

The lunar inequalities which we have as yet considered are all of a periodic nature. But there are others of a different kind, the periods of which are so long that, with reference to the duration of human life, they may be considered as permanently affecting the elements of the lunar orbit. These are the *Secular Inequalities*, the most remarkable of which is the *acceleration of the moon's mean motion*.

Lunar acceleration.

On comparing the lunar observations made within the last two centuries with one another, there results a mean secular motion greater than that which is given by comparing them with those made by Ibn-Junis, near Cairo, towards the end of the 10th century, and greater still than that which is given by comparing them with observations of eclipses made at Babylon in the years 719, 720, and 721 before our era, and preserved by Ptolemy in the *Almagest*. This acceleration of the moon's mean motion was first remarked by Dr Halley, and was fully confirmed by Dunthorne, who was led, by the discussion of a great number of ancient observations of eclipses, to suppose that it proceeded uniformly at the rate of 10″ in 100 years. This was the first attempt to estimate the value of the secular equation, which had hitherto been confounded with the mean secular motion. Mayer was led to the value 7″, which he advanced to 9″ in his last tables published in 1770. Lalande found it to amount to 9″·886. In 1786 Laplace demonstrated that the acceleration is one of the effects of the attraction of the sun, and connected with the variations of the eccentricity of the earth's orbit, in such a manner that the moon will continue to be accelerated while the eccentricity diminishes, but cease to be accelerated when the eccentricity has reached its maximum value; and when that element begins to increase, the mean motion of the moon will be retarded. Professor Adams, however, has recently shown that though a portion of the acceleration is undoubtedly due to the cause assigned by Laplace, in reality one-half or thereabouts remains unexplained by that cause. The researches of Delaunay confirm this view. The theory is entertained that the unexplained part of the acceleration is only apparent, the real cause in operation being a retardation of the earth's motion of rotation.

The same cause which gives rise to the acceleration of the mean motion, namely, the diminution of the eccentricity of the earth's orbit, also occasions secular inequalities in the motion of the perigee and nodes of the orbit of the moon. These two inequalities are, however, affected with opposite signs to that of the former, that is, while the mean motion of the moon is accelerated, the motion of her perigee and that of her nodes are retarded. By pushing the approximations to a great length MM. Plana and Carlini, and M. Damoiseau, in *Memoirs* which obtained the prize of the Academy of Sciences for 1820, found different numbers; those of Damoiseau are 1, 4·702, and 0·612.

The three secular inequalities which have been pointed out will obviously occasion others, for all quantities depending on the mean motion, the motion of the perigee, or of the nodes, must be in some degree modified by them. They can only be developed by the complete integration of the differential equations of motion. What is most essential is to select, among the multitude of terms, such as may possibly acquire considerable co-efficients by integration.

Various lunar months.

Understanding by the term *month* the time which the moon employs to make an entire revolution relatively to any given point, movable or fixed, we have as many different species of months as there are different motions with which that of the moon can be compared. For example, if we estimate her revolution relatively to the sun, the month will be the time which elapses between two consecutive conjunctions or oppositions. This is called the *synodic month*, *lunar month*, or *lunation*. If we consider her revolution as completed when she has gone through 360° of longitude counted from the movable equinox, we shall have the *tropical* or *periodic month*. The interval between two successive conjunctions with the same fixed star is the *sidereal month*. A revolution with regard to the apsides of her orbit, that is to say, the time in which she returns to her perigee or apogee, gives the *anomalistic month*. And, finally, the revolution with regard to the nodes is the *nodical month*.

It is clear that, taking the sidereal lunar month as a standard of reference, any other month will be greater or less according as the point which defines it moves in the same direction around the star-sphere as the moon or in the reverse direction, and that the excess or defect will be greater or less as such motion is more or less rapid. Thus, as the sun advances with considerable rapidity, the synodical month will much exceed the sidereal month; as the point ♈ retrogrades very slowly, the tropical month is very slightly less than the sidereal month; as the apsides advance, on the whole completing a revolution in 8·85 years, the anomalistic month will exceed the sidereal, but only by about $\frac{100}{885}$ths the excess of the synodical month; while, as the nodes retrograde, on the whole, completing a revolution in about 18·6 years, the nodical month will fall short of the sidereal by a defect equal to about $\frac{10}{186}$ths of the excess of the synodical month. This is illustrated in the following table presenting the values of the different lunar months. (See further the table of Lunar Elements, p. 782):—

		Differs from Sidereal Month.
Synodical month	29·53059 days.	+ 2·20893 days
Sidereal ,, ...	27·32166 ,,	0·00000 ,,
Tropical ,, ...	27·32156 ,,	− 0·00010 ,,
Anomalistic ,, ...	27·55460 ,,	+ 0·23294 ,,
Nodical ,, ...	27·21222 ,,	− 0·10944 ,,

The moon at all times presents very nearly the same face to the earth. If this were rigorously the case, it would follow that the moon revolves about an axis perpendicular to the plane of her orbit in the same time in which she completes a sidereal revolution about the earth, and that the angular velocities of the two motions are exactly equal. It is, however, proved by observation, that there are some variations in the apparent position of the spots on the lunar disk. Those which are situated very near the border of the disk alternately disappear and become visible, making stated periodical oscillations, which indicate a sort of vibratory motion of the lunar globe (apparent only), which is known by the appellation of the *Libration*.

Libration.

The rotation of the moon is sensibly uniform, while the motion of revolution is variable. The apparent rotation occasioned by the revolution of the moon round the earth is, consequently, not exactly counterbalanced by the real rotation, which remains constantly the same. Hence the different points of the lunar globe must appear to turn about her centre, sometimes in one direction, and sometimes in the contrary, and the same appearances be produced as would result from a small oscillation of the moon, in the plane of her orbit, about the radius vector drawn from her centre to the earth. The spots near the eastern or western edge of her disk disappear according as her motion in her orbit is more or less rapid than her mean motion. This is called the *Libration in Longitude*. Its maximum value corresponds to a rotation through 7° 45′

Further, the axis of rotation of the moon is not exactly perpendicular to the plane of her orbit; hence the two poles of rotation, and those parts of her surface which are near these poles, are alternately visible from the earth. This is the *Libration in Latitude*. Its maximum value amounts to 6° 44′.

Again, the observer is not placed at the centre of the earth, but at its surface. Thus in the course of a day the moon appears to oscillate about her radius vector because of the earth's rotation. This phenomenon constitutes what is called the *Diurnal Libration*, and is evidently the effect of the lunar parallax, and corresponds to it in amount, measured in minutes of arc. It therefore never exceeds 1° 1′ 28″·8.

The libration in latitude and the diurnal libration were discovered by Galileo soon after the invention of the telescope. It was Hevelius who discovered and first explained the libration in longitude. Regarding libration in general, it remains to be stated that, instead of one-half of the moon remaining invisible, about 4111 parts out of 10,000 are absolutely and at all times unseen. If diurnal libration be neglected, about 4198 parts out of 10,000 may be regarded as altogether unseen.

The nodes of the lunar equator coincide with those of the moon's orbit. The mean inclination of the lunar

Moon's inclination. equator to the ecliptic is 1° 28′ 42″. Mr Baily makes it 1° 30′ 11″·3. Since the descending node of the equator coincides with the ascending node of the orbit, it is evident that its plane lies on one side of a plane parallel to the plane of the ecliptic, while the plane of the orbit lies on the other. Thus the plane of the equator makes an angle of about 1° 30′ with the first, and of 6° 39′ with the second, on the average. But these angles are slightly variable.

The coincidence of the nodes of the lunar equator and orbit ranks among the most curious discoveries of modern astronomy. It was shown by Lagrange to be a necessary consequence of the attraction which the earth exercises on the lunar spheroid.

Spots on the moon. The various features of the moon's surface have been observed with great interest since the discovery of the telescope, and astronomers have been at much pains to determine their selenographic positions. On account of their number, it has been found necessary to distinguish them by particular names. Riccioli designated the most conspicuous of them by the names of astronomers and other eminent men. Hevelius gave them the names belonging to countries, islands, seas, and regions on the earth, without reference to situation or figure. The nomenclature of Riccioli is now universally followed. Delineations of the lunar disk have been given by Hevelius, in his *Selenographia*, by Cassini, Russell, Schröter, Lohrmann, and others. The subjoined engraving (fig. 36) gives a pretty accurate view of the appearance of the moon in her mean libration.

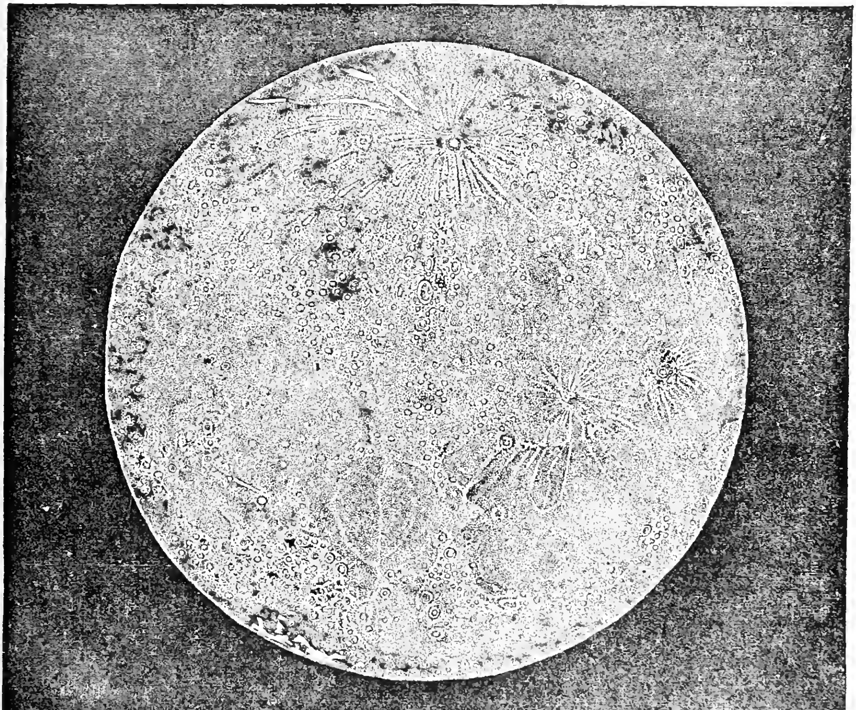

FIG. 36.—The Moon in her mean Libration (telescopic or inverted view).

That there are great inequalities on the surface of the moon is proved by looking at her through a telescope at any other time than when she is full; for then there is no regular line bounding the dark and illuminated parts, but the confines of these parts appear as it were toothed and cut with innumerable notches and breaks; and even in the dark part, near the borders of the enlightened surface, there are seen some small spaces illuminated by the sun's beams. It is impossible that this should be the case, unless these shining points were higher than the rest of the surface, so that the rays of the sun may illumine their summits before they reach their basis. Portions of considerable extent are also perceived on the lunar surface, which are never brilliant like the other parts, but remain constantly obscure. These are thought by some to be old sea-bottoms; they were formerly supposed to be seas, but this idea has been abandoned. Some of these cavities are upwards of four English miles in depth, and forty in circumference at the orifice. An insulated mountain is frequently observed to rise in the centre of these enormous pits or caverns, and they are surrounded by high annular ridges, the masses of which would fill the enclosed cavities.

Herschel imagined that he even observed volcanoes in activity; but it is now known that he mistook for volcanic light the effects of earth-light reflected from those parts of the moon's surface which have the highest reflective capacity. It has been urged that, as the brightness of the moon is sensibly equal at all times, she cannot be surrounded by an atmosphere similar to that of our earth. Moreover, if a lunar atmosphere existed, its influence would be perceptible in the occultations of the planets, or fixed stars, by the moon. The effects of refraction as exerted by an atmosphere resembling the earth's would cause a star to remain visible for a considerable time after it had really passed behind the moon's globe. In fact, it is easily shown that an atmosphere like our earth's would prevent any star from being concealed at all. It would render visible a star really placed directly behind the moon's centre; for the actual refractive effect required for this purpose would correspond to a deviation of the rays of light by about 16′, or 8′ in entering, and 8′ in passing out of the lunar atmosphere. Now the earth's atmosphere produces a refractive effect of 34′ on an orb in the horizon, or more than four times as much as would be required in a lunar atmosphere in order to render visible a star directly beyond the moon's centre. In point of fact, stars are occulted by the moon the instant they reach her edge; or if at any time there is apparent delay, this is such only as may be fairly attributed to the effect of irradiation.

In recent years the surface of the moon has been studied with increased care.

Lohrmann, a land surveyor of Dresden, planned the construction of a lunar chart on a large scale in twenty-five sections, and in 1824 the first four sections were published. He was unable, however, to complete this arduous task, as failing sight compelled him to desist. He published in 1838 a good general chart of the moon, 15¼ inches in diameter.

Amongst contributions to this department of astronomical research must be mentioned the well-executed map by Messrs Beer & Mädler (see their work *Der Mond*). It is the result of several years' careful study and micrometrical measurement of the surface of the moon, and every point discovered by the telescope has been laid down with great precision. In *Der Mond* these astronomers give the measurements of 919 spots, and 1095 determinations of the height of lunar mountains.

Schmidt of Athens has completed the most important contribution yet made to selenographic research. Passing over his earlier and, in his own estimation, unsatisfactory processes of charting, commenced in 1839, we may note that, according to his present plan, the complete chart has a diameter of 6 feet. It is constructed, however, in 25 sections (after Lohrmann's plan), and these are now completed. But the work still awaits publication, as the expenses of engraving must be very great, and are beyond Schmidt's means.

Lunar photography. Photography has been applied successfully to the work of picturing our satellite, though it will probably be long before photographic charts can be produced comparable with the work of Schmidt, or even of Beer and Mädler, so far as details are concerned.

The moon was first photographed by Dr J. W. Draper of New York, in 1840. Bond photographed the moon successfully in 1850, using the telescope of the Cambridge (U.S.) Observatory. Between the years 1850 and 1857, the moon was photographed by Secchi in Rome, Bertch and Arnauld in France, Phillips, Crookes, Hartnup, De la Rue, Fry, Huggins, Dancer, Baxendell, and others in England. Later, De la Rue produced lunar photographs of remarkable accuracy and beauty. But the very best pictures of the moon yet obtained are by Rutherfurd of New York, using a refractor of 11¼ inches aperture, and 13 feet focal length, corrected for the chemical rays.

Moon's brightness. A series of interesting researches has been made into the light-reflecting capacity, or, in point of fact, the *whiteness* of our satellite, by Zöllner of Leipsic. Bouguer had assigned to the moon a brightness equal to $\frac{1}{300000}$th part of the sun's. Wollaston made the proportion much smaller, determining it at $\frac{1}{801070}$th only. Zöllner employed two different methods of research. In one he determined the moon's illumination by tests of her surface brightness; in the other he obtained point-like images of the sun and moon for comparison with corresponding images of candle-flames. The results, lying between those obtained by Bouguer and Wollaston, are also in close agreement *inter se*. According to the former method, the light of the full moon is $\frac{1}{618000}$th part of the sun's light; according to the other, the proportion is as one to 619,000.

But the most interesting results obtained by Zöllner are those relating to the varying brightness of the moon at her different phases. He found that the defect of light when the moon is not full is much greater than it would be if the moon were a smooth but unpolished globe. From the agreement between the observed results and an empiric formula, intended to correspond for phases within 70° of the full moon with the case of an orb grooved meridionally so that the slopes of the grooves' sides are inclined 52° to the surface, Zöllner infers that the average slope of the lunar elevations amounts to about 52°. The following table indicates the degree of approximation :—

Arc from Moon's place to point opposite the Sun.	Theoretical Brightness. Full Moon's as 100.		Observed Brightness.
	Moon regarded as smooth.	By Zöllner's formula.	Zöllner

Chapter XI.—*Eclipses of the Sun and Moon.*

Eclipses. Strictly speaking, the term eclipse extends to all cases in which one celestial body is wholly or partially obscured by another, either by direct intervention or by the interception of light illuminating the former, so that the term includes transits of inferior planets, the concealment of stars by the moon or by a planet, or the concealment of a satellite by its primary. But the term eclipse is for convenience limited to the three following orders of phenomena :—(1.) The total or partial concealment of the sun by the moon, called a *solar eclipse*. (2.) The obscuration of the moon by the shadow of the earth, called a *lunar eclipse*. (3.) The concealment of a satellite of a planet by the shadow of the primary, called *eclipses of satellites*, and distinguished from *occultations* in which the *disk* of the primary hides the satellite from view.

Solar and lunar eclipses can be considered together, so far as the general law of their sequence is concerned. From what has been already shown, it follows that, if the motions of the sun and moon could be watched continuously from the centre of the earth, the moon would be seen to pass round the star-sphere once in each sidereal month on a path inclined about 5° 8′ to the ecliptic, while the sun would complete the circuit of the ecliptic once in a sidereal year; and the moon would pass the sun's place once

Seasons. in each synodical month. The place of conjunction of the sun and moon would clearly pass round the star-sphere, advancingly, making the complete circuit of the heavens once in each year on the average; and the same would happen with the place of conjunction of the moon and the point directly opposite the sun. Moreover, as the moon at these conjunctions would, of course, be on her own apparent orbit, and that orbit is inclined to the sun's, it is clear that, supposing the moon's orbit fixed, the conjunctions of sun and moon during one-half of the year would occur with the moon in the northern half of her apparent orbit, and those in the other half would occur with the moon in the southern half of her orbit. The same would be true of the conjunctions of the moon with the point opposite the sun, only, of course, the halves of the lunar orbit would be interchanged. At or near the time when the place of either conjunction was crossing from the northern to the southern side of the moon's orbit, or *vice versa*, the conjunction would occur with the moon so near to the ecliptic, that if the conjunction was one of sun and moon, she would hide the sun's disk wholly or partially, while, if the conjunction was one of the moon with that point opposite the sun towards which the earth's shadow is thrown, she would enter that shadow wholly or partially. In other words, at two seasons separated by six months there would be eclipses of the sun or moon, or both, whereas during the intervening months no eclipses would occur.

The number of eclipses which could occur in either eclipse-season would depend on the rate at which the points of successive conjunction approached and left the ecliptic, on the proximity necessary for the occurrence of an eclipse of either sort, and also on the manner in which the lunar node happened to be passed. For example, suppose that a conjunction of the sun and moon occurred when the moon was exactly at a node, so that a central eclipse of the sun occurred; then, half a synodical month before and half a synodical month after that conjunction, there would be a conjunction of the moon with the point opposite the sun, and the moon being only half a month's journey from her node, would be at a point of her orbit not far from the ecliptic. But the extent of the earth's shadow is such, that the moon would only be partially in the penumbra, and penumbral lunar eclipses are not considered by astronomers. There would therefore be only one eclipse in such an eclipse-season, viz., a central solar eclipse. Next, suppose that when the moon was at her node, she was exactly opposite the sun, then there would be a total lunar eclipse. Half a lunation later and earlier she would be in conjunction with the sun, and she would be at a point of her orbit not far from the ecliptic. In this case, although during half a month from nodal passage the moon supposed to be viewed from the earth's centre gets to a distance from the ecliptic exceeding the sum of her own and the sun's semidiameters, and therefore *so viewed* would pass clear of the sun, yet for the earth, regarded as a whole, she would not pass quite clear of the sun. In other words, for those parts of the earth where the effect of parallax would shift the moon most towards the sun, there would be a slight partial solar eclipse at the conjunction following or preceding the total lunar eclipse. In this case, then, there would be three eclipses, one lunar and total, the other two solar and partial. These results would be approximated to if the conjunction of sun and moon in the first case, or of moon and sun-shadow in the second case, occurred with the moon very near a node. But otherwise there would be an eclipse either solar or lunar a few days before her nodal passage, and another either lunar or solar a few days after her nodal passage, and no other eclipse of either sort in that eclipse-season.

All this corresponds to the actual conditions except in one respect. The lunar nodes retrograde, so as to meet the advancing conjunction-points of either kind, and thus, instead of a year being occupied in the complete circuit of the conjunctions, the actual interval has for its mean value the mean interval between the successive conjunctions of the sun with the rising node of the moon's orbit, or 346·607 days. Accordingly, the average interval between successive eclipse-seasons is 173·3 days instead of half a sidereal year.

Eclipses of both sorts are illustrated in fig. 37. Here E Theory of
is the earth, and the moon is shown in two places—at M, eclipses.
directly between the earth and sun, and at the point opposite M, in the heart of the earth's shadow-cone. The true geometrical shadows of the earth and moon are shown black, the true geometrical penumbræ are shaded (of course the vertical dimensions in the figure have been enormously exaggerated). The distance EC is variable, being as great

Fig. 37.

as 870,300 miles when the earth is in aphelion, and as small as 843,300 miles when the earth is in perihelion. The earth's shadow thus extends about $3\frac{1}{4}$ times as far from the earth as the moon's orbit. In figs. 38 and 39 the extremity of the moon's shadow is shown on a larger scale, in one case falling short of the earth, in the other extending beyond the earth. For the moon's conical shadow has a length which varies in the same proportion as the earth's shadow, that is, as 8703 to 8433; and the absolute length thus varies from 229,780 miles (fig. 38) to 237,140 miles (fig. 39). Since the moon's greatest mean and least distances are respectively 252,984 miles, 238,818 miles, and 221,593 miles, it follows that for solar eclipses we have—

Fig 38

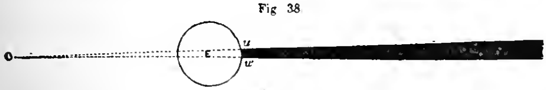

Fig 39.

Sun in perigee	☽ in apogee	Point C is 23,204 miles from earth (fig. 38).
	at mean distance	Point C is 9038 miles from earth (fig. 38)
	in perigee	Point C is 8187 miles beyond earth (fig. 39).
Sun in apogee	☽ in apogee	Point C is 15,844 miles from earth (fig. 38).
	at mean distance	Point C is 1678 miles from earth (fig. 38).
	in perigee	Point C is 15,547 miles beyond earth (fig. 39).

These numbers correspond to the fact that the limits between which the apparent diameter of the sun varies are 32′ 36″·4 and 31′ 31″·8, while the lunar disk varies in diameter from 33′ 31″·1 to 29′ 21″·9, so that in a central solar eclipse, where the sun is in perigee and the moon in apogee, the sun's disk extends beyond the moon's by

$$\tfrac{1}{2}\,(32'\,36''\cdot4 - 29'\,21''\cdot9),\ \text{or by } 1'\,37''\cdot2\,;$$

while the sun is in apogee and the moon in perigee, the moon's disk extends beyond the sun's by

$$\tfrac{1}{2}\,(33'\,31''\cdot1 - 31'\,31''\cdot8)\ \text{or by } 59''\cdot6.$$

In the former case, or any case in which the sun's disk exceeds the moon's so that in central eclipse a ring of sunlight is seen, the eclipse is called an *annular solar eclipse;* while, if the moon's disk exceeds the sun's, and the whole of the sun is thus eclipsed, when the centres of the disks coincide, the eclipse is called a *total* solar eclipse. When only a part of the sun is hidden, and no annulus is formed, the eclipse is called a *partial* solar eclipse. It is clear that an eclipse which is total or annular for certain parts of the earth will be partial elsewhere; and in cases (which occur very seldom, however) where the point C falls between E and *a*, fig. 38, the eclipse will be total along a certain part of the central track, and annular along the rest of that track. In a total eclipse the greatest possible breadth of the total shadow *uu′* (fig. 39) is about 173 miles. This is the *minor* axis of the shadow-ellipse.

The following table, combined with the fact that the moon's greatest apparent diameter is 33′ 31″·8, will be sufficient to illustrate the general conditions of lunar eclipses and the limits for totality:—

		Apparent diameters of earth's shadow. °	′	″
Sun in perigee.	☽ in apogee	1	15	24·30
	at mean distance	1	23	2·31
	in perigee	1	30	40·31
Sun at mean distance,	☽ in apogee	1	15	56·86
	at mean distance	1	23	34·87
	in perigee	1	31	12·87
Sun in apogee,	☽ in apogee	1	16	28·29
	at mean distance	1	24	6·30
	in perigee	1	31	44·80

Eclipse limits. It may be added that an eclipse of the sun can only occur when the moon at the time of mean conjunction with the sun is within $19\frac{2}{3}$° of her node, and will certainly occur if she is within $13\frac{1}{2}$°. A lunar eclipse can only happen when she is within $13\frac{1}{3}$° of her node, at the time of mean opposition to the sun, and will certainly occur if she is within 7°; but the limits are somewhat wider than those for solar eclipses, if penumbral lunar eclipses be counted. It is convenient to notice that in every period of 21,600 lunations there are, on the average, 4072 solar eclipses and 2614 lunar eclipses, besides 1617 penumbral lunar eclipses—that is, 4231 lunar eclipses including penumbral ones.

Number of eclipses annually. Noting that eclipse-seasons last on the average about 33 days, and that three eclipse-seasons each having three eclipses cannot occur in succession, it is easy to determine the greatest and least number of eclipses which may occur in any single year. The average interval between successive eclipse-seasons is 173·3 days. Two such intervals amount together to 346·6 days, or fall short of a year by about 19 days. Hence there cannot be three eclipse-seasons in a year; for each eclipse-season lasts on the average 33 days. Suppose an eclipse-season to begin with the beginning of a year of 366 days. The middle of the season occurs at about midday on January 17; the middle of the next eclipse-season 173·3 days later, or on the evening of July 8; and the middle of the third occurs yet 173·3 days later, or on December 29, early in the forenoon; so that nearly the whole of the remaining half belongs to the following year. This is clearly a favourable case for the occurrence of as many eclipses as possible during the year. If all three seasons could be of the class containing three eclipses, there would be eight eclipses in the year, because the second eclipse of the third season would occur in the middle of that season. This, however, can never happen. But there may be two seasons, each containing three eclipses, followed by a season containing two eclipses, only one of which can occur in the portion of the eclipse-season falling within the same year. In this case there would be seven eclipses in the year. So also there would be seven if in the first season there were three, in the second two, and in the third three, for then the portion of the third falling within the year, being rather more than one-half, would comprise two eclipses. So also if the three successive seasons comprise severally two, three, and three eclipses. The same would clearly happen if the year closed with the close of an eclipse-season.

There may then be as many as seven eclipses in a year, in which case at least four eclipses will be solar, and at least three of these partial, while of the lunar eclipses two at least will be total.

As regards the least possible number of eclipses, it is obvious that, as there must be two eclipse-seasons in the year, and at least one eclipse in each, we cannot have less than two eclipses in the course of a year. When there are only two, each eclipse is solar and central.

As regards intermediate cases, we need make no special inquiry. Many combinations are possible. The most common case is that in which there are four eclipses—two solar and two lunar. Further, it may be noticed that, whatever the number of eclipses, from two to seven inclusive, there must always be two solar eclipses at least in each year.

Chapter XII.—*The Planet Mars.*

After Venus, Mars is the planet whose orbit is nearest Mars. to the earth. His diameter is about 4400 miles, and his volume about one-sixth of the earth's; his mass, however, is little more than one-ninth of hers, his density being estimated at only $\frac{7}{10}$ths of the earth's. His mean distance from the sun is about 139 millions of miles; but the eccentricity of his orbit amounting to 0·093262, his greatest and least distances differ considerably from this mean value, amounting to 152,304,000 and 126,318,000 miles respectively. It follows that his distance from the earth when in opposition varies largely—in opposition near his perihelion his distance is about 33,800,000 miles, whereas, when he is near aphelion, his opposition-distance amounts to 61,800,000 miles. As he is also more brightly illuminated by the sun when in perihelion, it follows that he appears much brighter when in opposition at that part of his orbit. In fact, the brightness of Mars at opposition near perihelion bears to his brightness at opposition near aphelion, the ratio

$$(61{,}800{,}000)^2 \times (152{,}304{,}000)^2 : (33{,}800{,}000) \times (126{,}318{,}000)^2,\ \text{or about } 34 : 7.$$

In other words, the planet is nearly five-times as bright at one of the favourable oppositions as at one of the unfavourable. The planet's synodical period being 779·936 days, or two years and about 49½ days, it follows that the place of opposition performs a complete circuit of the ecliptic in an average period of rather more than 7 times the synodical period (for 7 × 49½ days = 346½ days, so that the change in the place of opposition nearly corresponds to the earth's yearly motion). The correspondence is nearer if two circuits of the ecliptic be taken; for 15 synodical revolutions are equal to 11,699·040 days, and 32 sidereal years are equal to 11,688·2048 days, or not quite 11 days less. But a much nearer agreement still is effected in 79 years, which differ by little more than two days from 42 sidereal revolutions of Mars. So that if at any time Mars in opposition has been very favourably placed for observation, the same condition of things, or very nearly so, will be brought about after 79 years. For instance, in the opposition of 1719, Mars was within $2\frac{1}{2}°$ of perihelion, and shone so brightly as to be mistaken for a new star. He was similarly situated at the opposition of 1798, and will again be so situated when in opposition in 1877.

Spots on Mars.

It is said that Fontana first noted the spots of Mars, and suspected the planet's rotation. But Fontana's credit is shaken by his alleged discovery of *seven* Jovian satellites. Cassini observed the spots at Bologna in 1666, and having continued his observations for a month, determined the planet's rotation-period as 24 h. 40 m. Observers at Rome, mistaking two opposite faces of the planet for the same face, deduced the period 13 h. Cassini in 1670 again observed the planet, obtaining the same rotation-period as before. Maraldi in 1704 noted changes in the shape of the spots; but from some which underwent little change, he deduced the rotation-period 24 h. 39 m. In 1719, when (as already mentioned) Mars was exceedingly well placed for observation, Maraldi again carefully observed the planet, deducing from the observations of 37 days a rotation-period identical with Cassini's.

Polar snows.

Besides the dark spots, which have a somewhat greenish colour, the rest of the disk being mostly ruddy, astronomers had noticed a portion of the disk around the south pole which was brightly white. Maraldi states that this spot had been observed for 60 years before his later observations were made. One part seemed fainter than the rest, and this portion was subject to considerable changes, occasionally disappearing, while the brighter part was constantly seen.

Sir W. Herschel examined a similar bright region around the north pole, which had not before his time been well seen, because the northern regions of the planet are only bowed towards us when the planet is traversing the parts of its orbit near aphelion. Herschel's powerful telescopes, however, enabled him to examine the planet during oppositions occurring in any part of the ecliptic. The magnifying powers he used were sometimes as high as 932, and with this the south polar spot was found to be 41″ in diameter. From these observations Herschel concluded that the diurnal rotation of Mars is accomplished in 24 h. 39 m. $21\frac{2}{3}$ s., that his equator is inclined to his orbit at an angle of 28° 42′, and his axis of rotation to the axis of the ecliptic at an angle of 30° 18′.

The bright appearance so remarkable about the poles of Mars was ascribed by Herschel to the reflection of light from mountains of ice and snow accumulated in those regions.

"The analogy between Mars and the earth," he says, "is perhaps by far the greatest in the whole solar system. Their diurnal motion is nearly the same, the obliquity of their respective ecliptics not very different; of all the superior planets, the distance of Mars from the sun is by far the nearest alike to that of the earth; nor will the length of the Martial year appear very different from what we enjoy, when compared to the surprising duration of the years of Jupiter, Saturn, and the Georgium Sidus. If we then find that the globe we inhabit has its polar regions frozen and covered with mountains of ice and snow, that only partly melt when alternately exposed to the sun, I may well be permitted to surmise that the same causes may probably have the same effect on the globe of Mars; that the bright polar spots are owing to the vivid reflection of light from frozen regions; and that the reduction of those spots is to be ascribed to their being exposed to the sun."

According to Herschel, the ratio of his equatorial and polar axes is 103 to 98. Schröter estimates the same ratio to be that of 81 to 80, but later observers have found no perceptible compression.

Charts of Mars.

Observations of Mars in recent times have added largely to our knowledge of the planet.

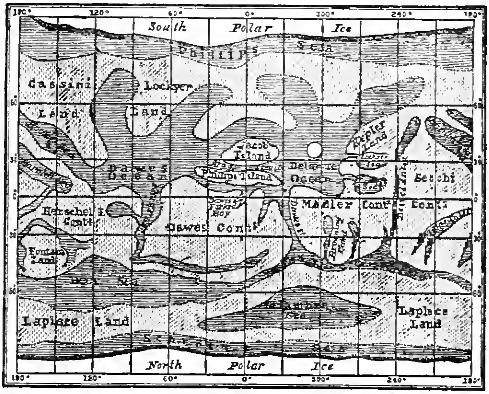

FIG. 40.—Chart of Mars on Mercator's Projection.

From drawings by Beer and Mädler (1830–1857), Dawes (1856–1866), De la Rue, Secchi, and others, Proctor has constructed the above chart of the planet (fig. 40).

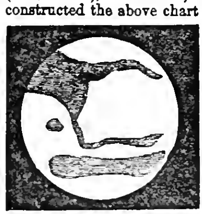

FIG. 41.—Mars, May 23, 1873, 9 G. M. T.

FIG. 42.—Mars, May 22, 1873, 11.30 G. M. T.

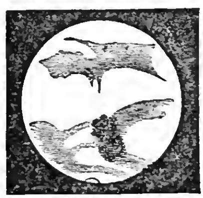

FIG. 43.—Mars, May 19, 1873, 12.30 G. M. T.

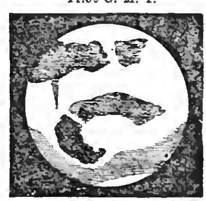

FIG. 44.—Mars, May 13, 1873, 12.30 G. M. T.

But the latest drawings, taken during the opposition of

1873, while showing excellent agreement with the chart as respects the southern parts of Mars, present some features in the northern hemisphere (more favourably seen in 1871 and 1873 than for many previous years) which are wanting in the above chart. This will be manifest from the views here given (figs. 41, 42, 43, and 44), obtained by Mr Knobel, F.R.A.S., with an 8-inch reflector of the Browning-With construction.

Compression. The shape of the planet has been repeatedly measured, but the results are not accordant. A set of measures made at Greenwich with a double-image micrometer in 1845 gave $\frac{1}{62}$ for the ellipticity, and another set in 1852 gave $\frac{1}{50}$. Arago contends for an ellipticity of $\frac{1}{30}$, the result of the Paris measures. But some observers can detect no difference between the polar and equatorial diameters, some even find the polar diameter longer than the equatorial. *Adhuc sub judice lis est.*

Rotation of Mars. The planet's rotation has been determined more accurately than was possible in Herschel's time. Beer and Mädler, from their observations in 1830–1837, deduced the rotation-period 24 h. 37 m. 23·8 s., and showed how Herschel had omitted to count one complete rotation when he deduced the period above mentioned. Kaiser of Leyden, by comparing his own observations in 1862 with those of Beer and Mädler, Sir W. Herschel, and finally (carrying back the research) with an observation made by Huyghens in 1672, deduced the period 24 h. 37 m. 22·62 s.

Proctor, by a similar process, extending from observations made in 1869 backwards to an observation by Hooke in 1666 (N.S.), deduced the period 24 h. 37 m. 22·735 s. Kaiser contended for the accuracy of his result, asserting that Hooke's pictures were less trustworthy than Huyghens's. But recently, in 1873, Proctor has detected three errors in Kaiser's computation, who has reckoned the years 1700 and 1800 as leap years instead of common years, and made a further error of a day in correcting Hooke's date from old style into new. When account is taken of these corrections, Hooke's observations and Huyghens's are easily reconciled. Due weight being given to each, the period 24 h. 37 m. 22·72 s. results, a value probably lying within 0·01 s. of the true sidereal rotation-period of the planet.

Atmosphere of Mars. It remains only to be added, that the spectroscopic observations of Mr Huggins show that the vapour of water is present in the atmosphere of Mars, a discovery of great interest and importance. A volume, however, instead of the limited space which is here available, would be required to discuss fully all that has been discovered respecting the planet Mars.

CHAPTER XIII.—*Asteroids, or Minor Planets.*

Discovery of Ceres. On the first day of the present century a new planet was discovered, which, although in one sense seeming to fill up a gap in the solar system, was yet unlike any hitherto known member of the planetary family. Kepler and Titius, followed in later times by Bode, had adopted the view that a planet was wanting to complete the symmetry of the solar system, as indicated by a certain law of progression in the planetary distances. This law is presented in the following table, which includes Uranus (known to Bode, but not to his predecessors in the recognition of this law):—

Mercury	Venus.	Earth.	Mars.	Missing Planet.	Jupiter.	Saturn.	Uranus.
4 0	4 3	4 6	4 12	4 24	4 48	4 96	4 192
4	7	10	16	28	52	100	196
3·9	7·2	10	15	...	52	95	192

Here the series 7, 10, 16, &c., is obtained by adding to 4 successively the numbers 3, 6, 12, 24, &c., forming a geometrical series; and the distances of Venus, the earth, Mars, Jupiter, &c., which are indicated in the lowest row, are found to correspond with the members thus obtained very closely indeed. Mercury is included in the above table, though the proper number to add to the constant 4 would be $1\frac{1}{2}$, not zero, and thus the distance of Mercury is really less than $\frac{8}{11}$ths of the proper distance according to the law of progression. And in passing it may be noticed that the distance of Neptune on the outside of the system differs as markedly from that indicated by the above law as the distance of the innermost known planet; for the law gives the distance of the next planet beyond Uranus as 388 on the scale above used, whereas the real distance of Neptune is 300 on that scale. However, towards the close of the last century, when Uranus had but lately been discovered and found to obey the law of distances, it was natural that the attention of astronomers should be directed to the strange gap in the series between Mars and Jupiter. So great was the confidence with which many now regarded the law, that the theory was advanced that a planet invisible to the naked eye was travelling within the seemingly vacant space; and through the exertions of Baron de Zach, an association of 24 astronomers was formed to search the zodiac for the unseen planet. Yet the discovery was not made by any member of this society. Wollaston had laid down a star in his catalogue where no star could be seen. Piazzi carefully examined the neighbourhood, to determine whether some star really existing there had been misplaced by Wollaston. On January 1, 1801, he noted a small star in Taurus, which on January 3 had changed its place. He wrote to Oriani and Bode; but the planet, which was at its stationary point, following opposition, on January 12, had become invisible owing to its approach to the sun, before the letter reached them, and Piazzi himself fell ill soon after. But Gauss the eminent mathematician undertook to compute the new planet's orbit and motions from the observations made by Piazzi, and at length, after long searching, De Zach rediscovered the planet on December 3, 1801, Olbers independently discovering it on the following evening. The planet was found to correspond well with the theory which had suggested the search for it, since its distance is 2·767 where the earth's distance is represented by unity, or 27·67 on the scale used in the above table. Piazzi gave to the new planet the name Ceres. Besides differing from the other known planets in being so small as apparently to belong to a different order, Ceres was found to have an inclination (of more than $10\frac{1}{2}°$) exceeding largely even that of Mercury. But these anomalous relations were soon found to be but the first indications of a discovery altogether more remarkable.

Pallas. During his long and arduous search for Ceres, Dr Olbers of Bremen had had occasion to examine with peculiar care the stars near her path. On March 28, 1802, he observed a star near Bode's stars 20 and 191 Virginis, where he felt sure that no star had existed during his former observations. After two hours it had moved very much as Ceres had done when he had first seen her almost in the same spot. Subsequent observations showed that this was a small planet (to which the name Pallas was given) travelling in an orbit having a mean distance of about 2·770 (earth's as 1), slightly exceeding, therefore, that of Ceres, but with an eccentricity of ·248, considerably exceeding that of any known planet, and an inclination of 34° 39′, exceeding the sum of the inclinations of all the other planets together. The effect of this great inclination on the geocentric position of the planet is even more remarkable than the heliocentric range of more than 69° in latitude. For when Pallas is at her greatest heliocentric latitude, and near opposition, her geocentric latitude exceeds 42°. This is very different from Venus's range of less than 9° in geocentric latitude, which had been regarded as the maximum, and had led astronomers to assign to the zodiac a breadth of 18°. A zodiac to include the asteroids should be 90° in breadth, and would cover $\frac{7}{10}$ths of the whole heavens.

Even more remarkable, however, was the discovery of two planets having nearly the same mean distance from the sun. The supposition that yet others might be found was naturally suggested; indeed, Olbers was led to conjecture that Ceres and Pallas are but fragments of a larger planet formerly circulating at the same distance, and shattered by some tremendous internal convulsion; and he proposed that search should be made where the paths of these planets nearly intersect. For if his theory were true, this must be the region where the explosion took place, and the fragments must continue to pass through that region.

Juno. While Harding of Lilienthal was charting the stars near the paths of Ceres and Pallas in the region thus indicated, he determined, on September 2, 1804, the position of a small star in Pisces, near 93 and 98 of Bode's catalogue. On September 4 the star was no longer in the same position. It was found to be a planet (to which the name Juno was given) travelling at a mean distance of 2·67 (considerably less than that deduced for Ceres and Pallas), in an orbit having eccentricity 0·257, and inclination 13° 1′. The effect of this great eccentricity is remarkable, as may be thus indicated:—supposing the apsides of the orbit to correspond to the planet's solstices, then the summer of one hemisphere is only half as long as the winter of that hemisphere, or as the summer of the other.

Vesta. Next Olbers, pursuing the same method, discovered Vesta, moving in an orbit having mean distance 2·373 (far less even than Juno's), eccentricity 0·0898, and inclination 7° 71′.

Later discoveries. A long interval then elapsed without the discovery of any new members of this remarkable family. It was not until December 8, 1845, that the fifth was recognised. On that night M. Hencke, an amateur astronomer of Driessen, discovered the body since named Astræa. He communicated his discovery to Encke and Schumacher, who confirmed it by observations made with more powerful telescopes. M. Hencke also discovered the sixth planet, on July 1, 1847. Since that time not a year has passed without the discovery of one or more minor planets; and in some years as many as ten or twelve have been added. At present (April 1875), the total number known amounts to 143, as shown in the following table, which gives also the names of the discoverers, as well as the date and place of discovery. It is to be observed that Melete, numbered 56, was mistaken for 41 till January 1859.

No.	Name.	Date of Discovery.	Discoverer.	Place of Discovery.

...s of Asteroids.

It has been shown by Leverrier, from the observed secular motion of the perihelion of Mars, that the combined mass of all the asteroids cannot exceed one-fourth of the earth's mass, even if the whole perturbation were ascribed to asteroids, and no account taken of the error in the estimated mass of the earth compared with the sun's. But as the recent new estimate of the sun's distance assigns a relatively increased mass to the earth, almost sufficient of itself to account for the observed motion of the perihelion of Mars, it appears to follow that the combined mass of the asteroids must be exceedingly small. Prof. Newcomb, of Washington, after carefully analysing the motions of the asteroids, comes to the conclusion, that, "though there are some peculiarities in the mutual relations between the orbits of these bodies which might favour Olbers's hypothesis, a much greater number of peculiarities negative the assumption."

Prof. Kirkwood, of Bloomington, Indiana, has shown that, when the mean distances of the minor planets are arranged in order of magnitude, certain gaps are recognised, that is, there are no asteroids having mean distances nearly equal to certain definite values. These values correspond to distances at which asteroids would revolve in periods associated with Jupiter's period by certain simple laws of commensurability. He infers, therefore, that the asteroids had an origin resembling that assigned to them by the nebular hypothesis. He compares the observed peculiarity to the existence of at least one great gap in the Saturnian ring system, showing that "a satellite revolving within that gap would have a period associated with the periods of Saturn's inner satellites, by similar simple laws of commensurability."

Chapter XIV.—*The Planet Jupiter.*

Jupiter is the largest planet of the solar system. Indeed he surpasses the rest so greatly, that the combined mass of all of them together would barely exceed two-fifths of his. This superiority is deserving of more consideration than it has commonly received. If we are justified in regarding our moon or the asteroids as belonging to a different order of bodies from the earth, Venus, Mars, and Mercury, because so much less than them in mass, we may not unreasonably regard Jupiter as belonging to a different order, because so much exceeding in mass the planets which travel within the zone of asteroids. The earth exceeds the moon only 81 times in mass, but Jupiter exceeds the earth in mass more than 300 times.

Jupiter travels at a distance from the sun exceeding the earth's $5\frac{1}{5}$ times, or at a mean distance of 475,692,000 miles. The eccentricity of his orbit is considerable, amounting to 0·048239, so that his greatest and least distances amount respectively to 498,639,000 miles and 452,745,000 miles. When in opposition, and at his mean distance, his distance from the earth amounts to about 361,000,000 miles. His orbit is inclined about 1° 18′ 40″·3 to the ecliptic. His sidereal revolution is completed in 4332·5848 days, or 11 years 314·92 days; whence it is easily calculated that his synodical period, or the interval separating his mean returns to opposition, has a mean value of 398·867 days. His mean diameter is nearly 85,000 miles in length, according to the best modern measurements, though strict accuracy cannot be claimed for this estimate, as the various determinations, even by the most skilful observers, differ considerably *inter se.* Until recently, the compression of his globe had been estimated at $\frac{1}{14}$, from the observations of W. Struve; but later measurements give $\frac{1}{17}$ as the compression. His volume exceeds the earth's 1233·205 times, but his density is only about one-fourth of hers, and his mass does not exceed hers more than 301 times.

Although the actual order of discovery would lead us to speak of the satellites of Jupiter before considering the features of his globe, it will be for several reasons more convenient to describe these features first. Cassini was the first to discover that Jupiter's globe is surrounded by belts apparently belonging to his surface. The features of these belts as described by Cassini are those which still continue to be recognised. Their number is variable; sometimes only one can be readily discerned, while at others the whole surface is covered by them. They are generally parallel to one another, as in fig. 45, but not always so. Their breadth is likewise variable, one belt having been Jupiter's belts.

Fig. 45.—Jupiter as seen Nov. 27, 1857, by Dawes.

Fig. 46.—Jupiter as seen Nov. 18, 1858, by Lassell.

observed to grow narrow, while another in its neighbourhood has increased in breadth, as if one had partially flowed into the other; and in this case a part of an oblique belt is commonly recognised between them, as if forming the channel of communication. Some of these peculiarities are illustrated in figs. 46, 47, and 48. Sometimes the belts

Fig. 47.—Jupiter as seen March 12, 1860, by Jacob.

Fig. 48.—Jupiter as seen April 9, 1860, by Baxendell.

remain unchanged for months; at others, new belts have formed in an hour or two. Although his surface appears Rotation.
thus variable, yet at times spots have been visible for several weeks, whose motions have served to indicate the law of the planet's rotation.

In 1665 Cassini observed a spot near the large central belt of Jupiter. It moved more quickly when near the middle of the disk than when near the edge, and also appeared narrower when at the edge, showing that it belonged to the surface (that is, to what appears as the surface) of the planet. This principal or ancient spot, as

(AS SEEN IN AN INVERTING TELESCOPE)

it is called, is the largest and most permanent of any yet discovered. It appeared and vanished eight times between the years 1665 and 1708, then continuing invisible till 1713. The spot has been frequently observed since, sometimes remaining visible for two or three years in succession, at others being unseen for as long or longer. It would be rash, however, to assume that the same spot has been seen, especially as there is reason to believe that a dark spot on Jupiter, instead of being a permanent feature of his surface (and only concealed from time to time by clouds), resembles rather a large spot upon the sun, an opening formed either by cyclonic disturbance in a deep atmosphere, or by some process of disturbance acting from beneath such an atmosphere. From various sets of observations made upon spots seen for long periods, the following rotation-periods have been deduced :—

	Jupiter's Rotation-Period h.	m.	s.
Cassini (1665)	9	56	0
Silvabelle	9	56	0
Schroter (1786)	9	55	33
Airy	9	55	25
Madler (1855)	9	55	26·6

Mädler's rotation-period is commonly regarded as the most reliable. It was based on observations commenced on November 3, 1834, and continued on every clear night until April 1835, a period including 400 revolutions. Two dark spots were visible when these observations were made. It need hardly be said, however, that very little reliance can be placed on the *seconds* in Mädler's, Airy's, or Schröter's determinations. In fact, there is clear evidence that spots on Jupiter are subject to a proper motion, like that which affects the spots on the sun. Schmidt, in No. 1973 of the *Astronomische Nachrichten*, gives a number of cases of such proper movements of spots, ranging in velocity from about 7 miles to about 200 miles an hour. It may be noted, also, that from a series of observations of one spot made between March 13 and April 14, 1873, with the great Rosse reflector, a period of 9 h. 55 m. 4 s. was deduced, while observations of another spot in the same interval gave a rotation-period of 9 h. 54 m. 55·4 s.

Physical condition of Jupiter.

The equator of Jupiter is inclined only 3° 5′ 30″ to the planet's orbit, so that there can be no appreciable seasonal changes. We should expect, therefore, a great calm to reign in the atmosphere of this planet, the more so that the sun's heat poured upon each square mile of it is (on the average) less than the 27th part of that received by each square mile of the earth's surface. Moreover, the seasons of Jupiter last nearly twelve times as long as ours, so that we should expect all changes in his atmosphere produced by solar action to take place with exceeding slowness. When, instead, we find signs of very rapid changes in the aspect of the belts, implying remarkable changes in the condition of the Jovian atmosphere, we seem compelled to recognise the operation of causes much more active than the heat poured by the sun on the distant orb of Jupiter. It seems natural to suppose that Jupiter's mass is itself intensely heated, and that such inherent heat produces these changes in the condition of his atmosphere. We find also in this theory an explanation of several remarkable circumstances, the significance of which has been somewhat strangely overlooked.

So soon as we institute a comparison between Jupiter and the earth, on the supposition that Jupiter is surrounded by an atmosphere bearing the same relation to his mass that the atmosphere of the earth bears to her mass, we find that a state of things would prevail in no sort resembling what we are acquainted with on earth. For the mass of Jupiter exceeds the earth's more than three hundredfold, while his surface exceeds hers little more than a hundredfold, so that the quantity of atmosphere above each square mile of surface would be three times greater on Jupiter than on the earth, and, owing to the greater force of gravity, the atmospheric pressure would still more largely exceed that on the earth. In fact, the density of the Jovian atmosphere at the surface would be more than six times as great as the density of our air at the sea level. Yet the extension of the atmosphere would be very much less in the case of Jupiter; for in our air the density is halved for each vertical ascent of $3\frac{1}{2}$ miles, whereas in the case of a Jovian atmosphere similarly constituted, the density would be halved for each vertical ascent of $1\frac{1}{2}$ miles. At a height, therefore, of $10\frac{1}{2}$ (7 times $1\frac{1}{2}$) miles from the surface of Jupiter the pressure would only exceed $\frac{1}{2^7}$ ($= \frac{1}{128}$th) that at his surface, or say $\frac{1}{20}$th that at the surface of our earth; whereas, at a height of $10\frac{1}{2}$ (3 times $3\frac{1}{2}$) miles from our sea level the atmospheric pressure is still equal to $\frac{1}{2^3}$ ($= \frac{1}{8}$th) that at the sea level, or $2\frac{1}{3}$ times as dense as the Jovian atmosphere at the same height under the supposed conditions.

We see that, in the case of Jupiter, under any assumption of resemblance in atmospheric constitution and condition, we should infer great density at the surface of the planet, but an exceedingly shallow atmosphere, the density diminishing much more rapidly with vertical height than in the case of our atmosphere; and if aqueous clouds formed in such an atmosphere, as in ours, they would occupy much shallower layers. Yet everything in the telescopic aspect of Jupiter implies that the cloud-layers are of great depth. In fact, their appearance shows that they are far deeper than the terrestrial cloud-layers. The disappearance of dark spots at a considerable distance from the limb of the planet, as observed by Mädler (who found that the two great spots by which he timed the planet's rotation became invisible at from 56° to 57° from the centre of the disk), would indeed imply that the darker inner region lay at an enormous distance below the upper light-reflecting layer. Yet even a depth of thirty or forty miles below the upper cloud-layer would not be consistent with any hypothesis of resemblance between the condition of Jupiter and the earth. Assuming a depth of only thirty miles, the atmospheric pressure would be increased 2^{20} times, or more than a millionfold, and the density in the same degree, if the atmosphere could retain the properties of a perfect gas at that enormous pressure. But such a density would exceed some fiftyfold the density of platinum, and of course no gas could exist as such at a thousandth part of this pressure.

Even when we place on one side the difficulty of reconciling observed appearances with the behaviour of gases under conditions with which we are familiar, a difficulty remains which cannot be removed without regarding Jupiter as utterly unlike our earth. If Jupiter had a shallow atmosphere, so that his solid globe were apparently of the same dimensions as the orb we measure, the mean density of such a globe would far surpass the earth's mean density, if the materials of the two globes were similar; for the pressure within the globe of Jupiter would be enormously greater. Yet we know that, instead of the density of Jupiter being greater than that of the earth, it is not one-fourth of hers. The theory that Jupiter's globe is hollow is inadmissible, because no shell of Jupiter's mass could resist the pressure generated by its own gravity. The alternative theory suggested by Brewster, that the substance of Jupiter and his fellow-giants of the outer planetary family may be porous, like pumice stone, is equally untenable for a like reason.

We seem forced, then, to the conclusion, that no resemblance exists between the condition of Jupiter and that of our earth. This being so, the theory to which we have been already led, that the condition and rapid changes of condition of the deep Jovian atmosphere are due to the planet's intense heat, suggests at once a solution of the difficulties just mentioned. These difficulties arose while we were dealing with Jupiter as a planet like our earth. But at the outset we noted, in his great volume and mass, the suggestion of a wide difference between his condition and that of our earth. Regarding him as belonging to a different class on account of his enormous size, and being led also to consider him as intensely heated, we may fairly compare him with a body known to be intensely heated, and of size enormously surpassing the earth, viz., with the sun. And though our difficulties are not in this way removed, yet we find that a much more complete analogy can be established between Jupiter and the sun than between the earth and Jupiter. Thus the density of the sun, like that of Jupiter, is small compared with the earth's; in fact, the mean density of the sun is almost exactly the same as that of Jupiter. The belts of Jupiter may be much more aptly compared with the spot-zones of the sun than with the trade-zones of the earth, which would certainly not present, as viewed from Mercury or Venus, any resemblance to the belts of Jupiter. The spots on Jupiter are not constant, and in this respect resemble the sun spots. They are like these also in having a proper motion. They change less rapidly, but this is intelligible when we consider how much less intensely heated Jupiter is than the sun.

Brightness of Jupiter, Saturn, &c.

It remains to be mentioned, in support of this theory of the inherent heat of Jupiter, that the light received from him is far greater than he would reflect if his surface were like that of the moon or of Mars. As the reasoning we have given has not been intended to relate solely to Jupiter, but to Saturn certainly, and probably to Uranus and Neptune, we may suitably present here a table which exhibits the relation between the light received from the various members of the solar system, and appears as markedly to distinguish the giant planets from the inner family, as the relations of size, mass, orbital scale, rapid rotation, and complexity of system, which have been longer known. From the observations of Zöllner, *Grundzüge einer allgemeinen Photometrie des Himmels*, Berlin, 1861, it appears that the light of the five planets at their mean opposition bears the following proportion to the light of the sun:—

			Probable Error. Per cent.
Sun =	6,994,000,000 times	Mars	5·8
Sun =	5,472,000,000 ,,	Jupiter	5·7
Sun =	130,980,000,000 ,,	Saturn (without the ring)	5·0
Sun =	8,486,000,000,000 ,,	Uranus	6·0
Sun =	79,620,000,000,000 ,,	Neptune	5·5

To which add two estimates of the moon's light, by comparing surfaces, and by comparing point-like images, of the sun and moon:—

		Probable Error.
Sun = 618,000 times	Moon	2·7 per cent.
Sun = 619,600 ,,	,,	1·6 ,,

Whence the average reflecting powers of the surfaces of the six orbs compared would be (on the assumption that the outer planets have no inherent light),—

Moon	0·1736	Saturn	0·4981
Mars	0·2672	Uranus	0·6400
Jupiter	0·6238	Neptune	0·4848

These results seem strongly to suggest that the four members of the outer family of planets shine partly by inherent lustre. The spectroscopic analysis of the light of Jupiter and Saturn, though not altogether satisfactory, indicates clearly the existence of a very deep vapour-laden atmosphere around each planet.

Satelites of Jupiter.

Soon after the invention of the telescope, Galileo discovered that four small orbs or satellites circle around Jupiter. Galileo soon found that their orbits are nearly circular, and their motions nearly uniform. They revolve in planes inclined little to the plane of the ecliptic, so that as viewed from the earth they appear to traverse very narrow ellipses. Even when these ellipses are most open, they all, save the outermost, have minor axes less than Jupiter's apparent diameter, so that any one of the three interior satellites is necessarily occulted when in superior conjunction with Jupiter as viewed from the earth, and eclipsed in his shadow when in superior heliocentric conjunction, while when in inferior geocentric conjunction, it is in transit across the planet's disk; and when in inferior heliocentric conjunction, its shadow is in transit. The same is true of the fourth satellite during about two-thirds of Jupiter's year, viz., for about one-sixth of his year before and after the two equinoxes (four sixths in all), the plane of the satellite's orbit being nearly coincident with the planet's equator. The elements of the satellites are given in the tables on p. 783, and the orbits are pictured to scale in Plate XXVIII. To the elements tabulated may be added these (the densities usually given in the books being altogether incorrect):—

	Density (earth's as 1).	Density (water as 1).
Sat. I.	0·198	1·148
,, II.	0·374	2·167
,, III.	0·325	1·883
,, IV	0·258	1·463

Thus all the satellites (except the first) have a density exceeding Jupiter's. Probably their real densities are greater, as irradiation increases their apparent size.

The motions of Jupiter's satellites have been very carefully studied. They had not been long observed before a peculiarity was recognised, which Roemer was the first to interpret. Their various phenomena were found to occur earlier when Jupiter was in opposition, and later when he was near conjunction, than the predicted time. (In conjunction, of course, he cannot be seen.) Roemer suggested that the time-difference is due to Jupiter's variations of distance from the earth,—light, which brings to our earth information of the phenomena, taking a longer time in reaching us when Jupiter is farther away. Ridiculed at first, this theory was before long established by repeated observation, and eventually placed beyond all question by Bradley's discovery of aberration. (See ABERRATION, vol. i. p. 48.)

A singular relation exists between the motions of Jupiter's three inner satellites. It will be observed from the table of elements that the period of the second is almost exactly double the period of the first, that of the third almost exactly double that of the second; in other words, the sidereal motions of I. II. and III. are almost exactly as the numbers 4, 2, and 1. This will be more clearly shown by the following table:—

	Sidereal Revolution in Seconds.	Sidereal Revolution per Second.
Sat. I.	152853·505	8·478706
,, II.	306822·040	4·223947
,, III.	618153·360	2·096567
,, IV.	1441931·271	0·898795

The coincidence is not exact; but the following relation holds *exactly*:—The sidereal motion of I. added to twice the sidereal motion of III. is equal to three times the sidereal motion of II. Thus—

$$(8''\cdot478706) + 2(2''\cdot096,567) = 12''\cdot671840$$
$$= 3(4''\cdot223947).$$

A result of this relation, combined with the fact that when

I. and III. are in conjunction II. is in opposition to both, is that the three satellites are never in conjunction together. Thus, starting from a conjunction of I. and III., with II. in opposition, we have, after almost exactly one revolution of I., II. and I. in conjunction, and III. in quadrature to both, after another, II. and III. are in conjunction, and I. in opposition to both; after another, II. and I. are in conjunction, and III. in quadrature to both; and after a fourth, the same arrangement is resumed as at first, I. and III. being in conjunction, and II. in opposition to both, but the line on which all four satellites now lie holding a slightly different position from that occupied when these circuits began. Thus the satellites can never be all occulted together, or all in transit together.

Chapter XV.—*The Planet Saturn.*

Saturn is the largest planet but one of the solar system, being surpassed in mass by Jupiter alone. His mass exceeds the combined mass of all the other planets (Jupiter excepted) nearly threefold. He is the sixth planet in order of distance from the sun, and was the remotest planet known to the ancients. He travels at a mean distance of 872,137,000 miles from the sun, his greatest distance being 920,973,000 miles, his least distance 823,301,000 miles. The eccentricity of his orbit is 0·055996, and the inclination 2° 29′ 28″ to the plane of the ecliptic. Saturn's mean sidereal period of revolution in his orbit is 29 years 167 days (see the *Elements*, p. 782); his mean synodical revolution, or the mean interval between his successive returns to opposition, is 378·090 days. The planet's mean diameter is about 70,000 miles, his polar diameter about 3500 miles less, his equatorial diameter about 3500 miles greater. In volume he exceeds the earth nearly 700 times, but in mass only about 90 times, his density being less than the earth's in the proportion of about 13 to 100. He rotates on his axis in about 10¼ hours, the plane of his equator being inclined nearly 27° to the plane of his orbit.

Saturnis rings. This planet, in consequence of a luminous ring with which he is surrounded, is one of the most interesting objects in the heavens. This singular appendage was first noticed by Galileo, to whom the planet presented a *triple* appearance, as if a large orb were situated between two small bodies or *ansæ*. He observed that sometimes the ansæ were so enlarged as to present the appearance of a continuous ring; at other times they entirely disappeared, and Saturn appeared round like the rest of the planets. After a certain time they again became visible, and gradually increased in magnitude. These curious appearances were shown by Huyghens to be occasioned by an opaque, thin, circular ring surrounding the equator of Saturn, and at a considerable distance from the planet. Saturn moving in the plane of his orbit, carries the ring along with him, which, presenting itself to the earth under different inclinations, occasions all the phenomena which have been described.

Disappearance of the rings. The ring being only luminous in consequence of its reflecting the solar light, it is evident that it can be visible only when the sun and the earth are both on the same side of it; if they are on opposite sides, it will be invisible. It will likewise be invisible in two other cases, namely, 1*st*, when its plane produced passes through the centre of the earth, for then none of the light reflected from it can reach us; and 2*d*, when its plane passes through the sun, because only its edge is then enlightened, and being very thin, the whole quantity of reflected light will scarcely be sufficient to render it visible. It is, however, evident that in these two cases the effect will be modified in some degree by the power of the telescope. In ordinary telescopes the ring disappears sometimes before its plane comes into either of the situations mentioned; but Herschel never lost sight of it, either when its plane passed through the earth or the sun. In the last case the edge of the ring appeared as a luminous line on the round disk of the planet, measuring scarcely a second in breadth, but at the distance of Saturn a second corresponds to 4000 miles, which is equal to the semidiameter of the terrestrial globe. The reason of the ring's disappearance will be easily understood by referring to fig. 49, where the circle *a b c d* represents the orbit of

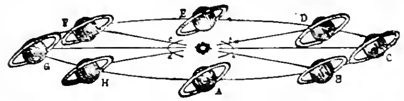

Fig. 49.—Diagram illustrating Different Appearances of Saturn's Rings.

the earth, A B C D that of Saturn 9½ times more distant from the sun. When Saturn is at A, the earth and sun are both in the plane of the ring; its edge is consequently turned towards us, and it will be invisible unless telescopes of very high power are used. See Plate XXIX. fig. 1. As Saturn advances from A to B, the ring gradually opens, see Plate XXIX. fig. 2, and it attains its greatest breadth at C, where a straight line perpendicular to its plane makes a more acute angle with the visual ray than in any other situation, see Plate XXIX. fig. 3. As the planet advances towards D, the plane of the ring becomes more oblique to the visual ray; the breadth of the ring consequently contracts, and it again disappears at E. From E to F, G, and A, the same phenomena will be repeated, only in this case it is the southern side of the ring which is visible to the earth, whereas, while Saturn was in the other half of his orbit, it was the northern side. These changes take place in a period whose full length is Saturn's year, or about 29½ of our years. Thus the interval between successive disappearances is about 15 years.

The brothers W. and J. Ball discovered a division separating the ring into two concentric rings, the inner being the wider. Cassini confirmed this discovery. Sir W. Herschel concluded that the matter of the ring is no less solid than that of Saturn, as it casts a strong shadow upon the planet. The light of the ring is generally brighter than that of the planet; for it appears sufficiently luminous when the telescope affords scarcely light enough for Saturn. The outer ring is much less brilliant than the inner. Division in the rings.

In observing the ring with very powerful telescopes, some astronomers have remarked, not one only, but several

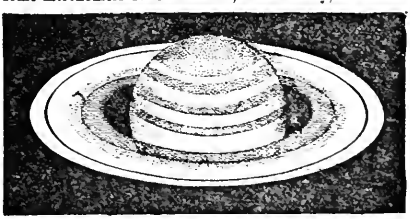

Fig. 50.—Saturn, as seen at Malta by Mr Lassell with a 20 feet Reflector on 9th October 1852.

dark concentric lines on its surface, which divide it into as many distinct circumferences. In common telescopes these are not perceptible; for the irradiation, by enlarging the space occupied by each ring, causes the intervals between them to disappear, and the whole seems blended together in one belt of uniform appearance. (See fig. 50.)

By means of some spots observed on the surface of the

Rotation of the rings. ring, Herschel found that it revolves in its own plane in 10 hours 32 min. 15·4 sec.; and Laplace arrived at the same result from theory. It is worthy of remark, that this is the period in which a satellite, having for its orbit the mean circumference of the ring, would complete its revolution according to the third law of Kepler.

The dark ring. Amongst the most remarkable discoveries of recent times with regard to the rings of Saturn is that of the *inner dusky or semi-transparent ring*, sufficiently obvious to any observer capable of using well a moderately good telescope, but which, previously to the year 1850, was only once mentioned by any astronomer. Dr Galle of Berlin saw this ring with the Berlin refractor in 1838, but the attention of the scientific world was not generally drawn to it. The account of Galle's observations is accompanied by drawings exhibiting the trace of the dusky ring where it crosses the body of the planet. In the year 1850 the ring was recognised almost simultaneously by two observers, namely, by Prof. Bond of the Cambridge Observatory, U.S., and by Mr Dawes. Since that time there has been no difficulty in seeing this appendage, though it requires a practised eye and a good telescope.

At the time of the discovery of the dusky ring, Mr Dawes also satisfactorily established the fact of the division of the exterior ring near its outer extremity; and subsequently he observed a series of discontinuous gradations of colour or intensity of brightness in a portion of the inner bright ring. He observes that "the exterior portion of the inner bright ring to about one-fourth of its whole breadth was very bright, but, interior to this, the shading-off did not appear, as under ordinary circumstances, to become deeper towards the inner edge without any distinct or sudden gradations of shade; on the contrary, it was clearly seen to be arranged in a series of narrow concentric bands, each of which was darker than the next exterior one. Four such were distinctly made out: they looked like steps leading down to the black chasm between the ring and the ball. The impression I received was, that they were *separate rings*, but too close together for the divisions to be seen in black lines." This curious phenomenon was confirmed afterwards by Professor Bond.

Captain Jacobs, at the Madras Observatory, discovered that the dusky ring is semi-transparent, the body of the planet being visible through it. M. Otto Struve shows with tolerable certainty that the inner or dusky ring is not a modern appendage to the planet, but that, at the beginning of the 18th century, the dark line thrown by it across the planet was known by the name of the *equatorial belt*. He also finds reason to believe, from a comparison of the measures of Huyghens, Cassini, Bradley, Herschel, W. Struve, Encke, Galle, and himself, that the *inner edge of the interior bright ring is gradually approaching the body of the planet, while at the same time the total breadth of the two bright rings is constantly increasing.*

Nature of the rings. The opinion now generally entertained respecting the Saturnian ring-system is, that it is composed of multitudes of minute satellites, probably intermixed with vapour, travelling independently around the planet. On no other supposition, indeed, can the permanence of the ring-system be explained.

Rotation and figure of Saturn. From observations of some obscure belts, and a very conspicuous spot on the surface of Saturn, Sir W. Herschel concluded that his rotation is performed in 10 hours 16 min., on an axis perpendicular to the belts and to the plane of the ring; so that the planes of the planet's equator and ring coincide. According to the same astronomer, the ratio of the equatorial and polar diameters of Saturn is 2281 to 2061, or nearly 11 to 10. He also observed that the globe of Saturn appeared to be flattened at the equator as well as at the poles. The compression he thought to extend to a great distance over the surface of the planet, and the greatest diameter to be that of the parallel of 43° of latitude, where, consequently, the curvature of the meridians is also the greatest. The disk of Saturn, therefore, resembled a square of which the four corners have been rounded off. According to recent measures the shape of the planet has been found to be that of an exact spheroid of revolution; but it does not follow that this is always the case. Applying to Saturn reasoning similar to that already employed in the case of Jupiter, we see that the atmospheric envelope may be so deep that the cloud-layers which the astronomer really measures may lie at different levels, under the varying conditions to which the planet is subject.

Saturn is surrounded by a system of eight satellites— the most extended as well as most numerous subordinate system within the sun's domain. The span of the orbit of the outermost satellite amounts to nearly 4 millions of miles. This satellite is probably larger than our moon, while Titan, the 6th satellite, is nearly as large as the planet Mercury. The elements of the satellites and the names of their discoverers are indicated in the table at p. 783. Their motions are less interesting to observers than those of Jupiter's satellites, because, owing to their considerable inclination to the plane of Saturn's orbit, they are seldom occulted by the planet, or transit across his disk. Saturnian satellites

CHAPTER XVI.—*The Planets Uranus and Neptune.*

Uranus is the seventh primary planet in order of distance from the sun, and, with the exception of Neptune, the remotest. His mean distance from the sun exceeds the earth's more than 19 times, and amounts to 1,753,869,000 miles. But the eccentricity of the orbit is considerable, amounting to 0·0466; consequently, the variation of the planet's distance is also great, his greatest distance amounting to 1,835,561,000 miles, his least to 1,672,177,000 miles. Subtracting roughly from his greatest, mean, and least distance the earth's distance, we obtain the opposition distances 1,744,000,000 miles, 1,662,500,000 miles, and 1,581,000,000 miles respectively; and, therefore, it is manifest that the planet is seen under much more favourable conditions in some oppositions than in others, especially if it is remembered that when at one of his nearer oppositions, Uranus, being also nearer to the sun, is more strongly illuminated, a point of great importance in the case of a planet so far from the sun. The sidereal revolution of Uranus is performed in 30,686·8208 days, or 84 years $6\frac{1}{2}$ days. His mean diameter is about 33,000 miles, and, as seen from the earth, Uranus in opposition subtends an angle of less than 4″. The apparent diameter of the sun seen from Uranus is less than $\frac{1}{19}$th of the diameter of the sun as we see him, or is but about $1\frac{2}{3}'$; and the apparent surface of the sun is but about the 367th part of the apparent surface of the sun we see. Accordingly, the light and heat received by Uranus are less in the same proportion. This refers, of course, only to the light and heat received per unit of surface. The whole globe of Uranus receives about $\frac{1}{24}$th part of the heat which is received by the whole globe of the earth. It has been asserted that Uranus turns upon an axis in about $9\frac{1}{2}$ hours, but the evidence on which this statement rests is slight and insufficient. Uranus.

Uranus was discovered by Sir W. Herschel on March 13, 1781, while he was examining the small stars in the neighbourhood of η Geminorum. Being struck with the enormous magnitude of a star in this region, he suspected it to be a comet. He examined it with higher power, and found the disk enlarged, which would not be the case with a star. He therefore announced the discovery of a comet. Discovery of Uranus

But it was found to be moving in a nearly circular path, and was presently recognised as one of the principal planets of the solar system. Herschel gave it the name of Georgium Sidus, and foreign astronomers called it Herschel; but the name Uranus, suggested by Bode, of Berlin, is now universally adopted. In 1787 Herschel discovered that it was attended by two satellites, and he subsequently supposed that he had discovered four others; but there is great reason to believe that he had mistaken small stars near the planet for satellites. Two other satellites inferior to the rest have been discovered by Mr W. Lassell, completing the series of four satellites whose elements are given at p. 783. Recently Prof. Holden of Washington, U.S., after careful study of the motions of all four satellites, has found reason for believing that one of those discovered by Sir W. Herschel (subsequently to satellites 3 and 4) is identical with satellite 2, while another seems not improbably identical with the innermost satellite. The satellites of Uranus are distinguished from all others in the solar system by the great inclination of their orbits to the ecliptic, amounting to nearly 80°, and by their retrograde motion. Hind gives 79° 26′ as the inclination of the orbits of Titania and Oberon (3 and 4), and for the longitudes of their rising nodes 165° 25′ and 165° 28′ respectively.

ranian tellites.

Little of interest has rewarded the telescopic study of Uranus; nor has the spectroscope given any trustworthy evidence, though Secchi, Huggins, and Vogel recognise peculiarities distinguishing the spectrum of Uranus from that due to reflected sun-light.

scovery Neptune.

The discovery of the planet Neptune ranks amongst the most brilliant of the scientific feats of the present century.

For many years the orbit of Uranus had been the occasion of great embarrassment to astronomers, from the impossibility of adequately reconciling the ancient and modern observations by any one set of elements, and from the rapid increase of the error from year to year. Bouvard early suggested that some planet exterior to Uranus caused these apparent irregularities. Amongst the astronomers who entered seriously upon the task of determining the position of such a disturbing planet two arrived at a successful solution of the problem, namely, Mr Adams and M. Leverrier.

Adams had, ever since the year 1841, determined on attempting the solution of the problem relating to the unknown disturbances of Uranus, and in 1843 he began his investigations. In September 1845 he communicated to Professor Challis the values of the elements of the orbit of the supposed disturbing planet, and in the following month he communicated to the astronomer royal the same results slightly corrected. These communications did not lead, however, to any steps being taken to secure by observation the discovery of the planet till the summer of 1846, after the publication of Leverrier's second memoir, in which the same position, within one degree, was assigned to the disturbing planet as that given in Adams' paper.

Leverrier undertook the task of revising the theory of Uranus at the instance of M. Arago. His first memoir on the subject was read before the French Academy in November 1845, and his second memoir in June 1846. A third memoir, entitled "*Sur la planète qui produit les anomalies observées dans le mouvement d'Uranus—Determination de sa masse, de son orbite, et de sa position actuelle,*" was read on August 31, 1846. A fourth memoir, containing the remaining part of M. Leverrier's investigations, was read after the discovery of Neptune on October 5, 1846.

The discovery of the disturbing planet followed almost immediately after the publication of the third memoir of Leverrier. He wrote to his friend Dr Galle, of Berlin, requesting him to search for the planet with the large refracting telescope of the Berlin Observatory, at the position which he indicated to him. This letter reached Berlin on September 23, and on the same evening Galle observed all the stars in the neighbourhood of the place indicated, and compared their places with those given in Bremiker's *Berlin Star-Map*. This map had not yet reached England, and on this circumstance probably depended the priority of discovery at Berlin. Galle very quickly found a star of about the eighth magnitude, nearly in the place pointed out, which did not exist in the map. Little doubt was entertained at the time that this was the planet, and the observations of the next two days confirmed the discovery.

After Leverrier had announced the results of his labours, agreeing, as we have seen, with Adams's results, the resources of the Cambridge Observatory were brought into use for the discovery of the planet, and a systematic search was begun by Professor Challis with the great Northumberland telescope. The sweeps of the portion of the heavens in which it was supposed the planet would be found were begun on July 29, and the planet was actually observed on August 4, but without recognition. After the discovery of the planet at Berlin, it was found that the planet had also been observed on August 12. If, therefore, Bremiker's map had been in the hands of Professor Challis, or if he had found leisure for the mapping of his observations from night to night, Neptune would have been infallibly detected within a very few days of the commencement of the search, and the whole glory of the discovery would have belonged to the English geometer.

An ancient observation in Lalande's catalogue was discovered almost simultaneously by Mr Walker, of the Washington Observatory, and by Dr Peters at Altona. Two observations, the one in October 1845, and another in September 1846, were also detected by Mr Hind in Lamont's *Zones*; and these (especially the former) contributed greatly to the construction of an accurate orbit. An excellent orbit was computed by the joint labours of the American astronomers Peirce and Walker.

Almost immediately after the discovery of Neptune, it was found to be attended by one satellite. This discovery was made by Mr Lassell in October 1846. The orbit of the satellite is inclined to the ecliptic at an angle of about 29°. By observations of this satellite at Cambridge (in America), and at Poulkowa, two separate values of the mass, namely, $\frac{1}{19840}$ and $\frac{1}{14496}$ have been deduced; but the object is so difficult to observe, that a considerable time must elapse before any very accurate determination can be obtained. The satellite is supposed to travel in a retrograde direction, like the satellites of Uranus; but this has not yet been demonstrated.

Neptune's satellite.

Chapter XVII.—*Comets.*

Comets.

The comets form a class of bodies belonging to the solar system, distinguished from the planets by their physical appearance and the great eccentricities of their orbits.

Orbits of comets.

While the orbits of all the planets are confined within a narrow zone, or to planes not greatly inclined to the ecliptic, those of the comets are inclined in all possible angles. The figures of the orbits, instead of being nearly circular, like those of the planets, often have the appearance of being almost rectilinear. Hevelius seems to have been the first who discovered, by means of a geometrical construction, that the orbits might be represented by parabolas; and Halley first calculated their elements on this hypothesis. After it was known, however, that certain comets return to the sun in the same orbits, it became necessary to adopt the opinion that, in conformity with the laws of Kepler, the cometary orbits are ellipses having the sun in one of the foci. As the ellipses are in general extremely elongated, and the comets are only visible while they describe a small portion of their orbits on either side of their perihelia, their paths during the time of their appearance differ very little from parabolas; whence it is usual, on account of the facility of computation, to assume that they really move in parabolic curves. Newton employed the hypothesis of an elliptic motion to compute the orbit of the famous comet of 1680. They have received the name of comets (*coma*, hair) from the *bearded* appearance which they frequently exhibit.

Halley's comet. One of the most remarkable periodic comets with which we are acquainted is that known to astronomers as Halley's. Having perceived that the elements of the comet of 1682 were nearly the same as those of two comets which had respectively appeared in 1531 and 1607, he concluded that all the three orbits belonged to the same comet, of which the periodic time was about 76 years. After a rough estimate of the perturbations it must sustain from the attraction of the planets, Halley predicted its return for 1757,—a bold prediction at that time, but justified by the event, for the comet again made its appearance as was expected, though it did not pass through its perihelion till the month of March 1759, the attraction of Jupiter and Saturn having caused, as was computed by Clairaut previously to its return, a retardation of 618 days. This comet had been observed in 1066, and the accounts which have been preserved represent it as having then appeared to be four times the size of Venus, and to have shone with a light equal to a fourth of that of the moon. History is silent respecting it from that time till the year 1456, when it passed very near to the earth: its tail then extended over 60° of the heavens, and had the form of a sabre. It returned to its perihelion in 1835, and the splendour of its appearance rendered it once more an object of universal interest; it was well observed in almost every observatory.

Lexell's comet. The orbit of the comet of 1770 was calculated by Lexell, and subsequently by Burckhardt, and both these astronomers found that the observations could only be represented by an ellipse in which the time of revolution was five years and a half; yet the comet has never been seen since, or at least has not been seen moving in the same orbit. Hence it is concluded with certainty that the attraction of Jupiter, near which planet it had passed, was so great as to compel it to move in a totally different ellipse.

Another famous comet, whose periodic returns have been verified by observation, received the name of Encke the astronomer, who first recognised it as having been observed in previous revolutions. It returns to its perihelion in 1208 days. Encke's comet, although its identity was not discovered till 1818, had been frequently observed, as in 1789, 1795, and 1805; and on these occasions it exhibited very different appearances, having been seen with and without a nucleus, and with and without a tail,—circumstances which account for its having so long escaped being recognised as a regular attendant on the sun. In its returns to its perihelion in 1808, 1812, and 1815, it escaped detection; but it reappeared in 1818, and it was from the observations of that year that Encke computed the elliptic elements of its orbit. On its next return, in 1822, it was invisible in Europe; but it was observed at Paramatta, in New South Wales, during the whole month of June, and the time of its perihelion passage was found to differ only by about three hours from that previously computed by Encke. During most of its returns since then it has been well observed.

Other periodical comets will be mentioned further on.

Phenomena of comets. The appearances exhibited by comets are diversified, and sometimes remarkable. That which appeared in the year 134 B.C., at the birth of Mithridates, is said to have had a disk equal in magnitude to that of the sun. Ten years before this, one was seen which, according to Justin, occupied a fourth part of the sky (that is, extended over 45°), and surpassed the sun in splendour. Another, equally remarkable, appeared in the year 117 of our era; and in 479 there was one, of which the disk, according to Freret, was of such magnitude, that it might have occasioned the extraordinary eclipse of the sun which took place about that time. In 400 one was observed, which is said to have resembled a sword, and to have extended from the zenith to the horizon. That of 531 was of greater magnitude still, and its appearance more terrific. Those which appeared in 1066 and 1505 exhibited disks larger than that of the moon. It is, however, probable that these accounts were exaggerated; for since comets have been observed by astronomers, no instances have occurred in which their magnitudes and appearances have been so extraordinary. The most remarkable among those of which we possess accurate accounts appeared in the years 1456, 1618, 1680, 1744, 1759, 1769, 1807, 1811, 1841, 1858, 1861, and 1874.

The nucleus, which is the densest and most luminous part, may be said to form the true body of the comet. It is far, however, from having the dense and solid appearance of the planets, and astronomers consider it to be diaphanous, and believe that they have observed stars through it. But it is extremely difficult to distinguish the nucleus from the surrounding nebulosity. If the nucleus were an opaque globular body, it would exhibit phases like Venus or Mars, according to its different positions with relation to the sun and the earth; and such were supposed to have been observed in the case of the comet of 1682, by Hevelius, Picard, and Lahire. But the nebulosity renders the phases obscure, and prevents the true body of the comet from being seen. The real nucleus has probably never been observed by any astronomer.

It is known certainly that comets are of small density, from the circumstance that they produce no appreciable effect on the motions of the planets. The comet of 1770 traversed the system of Jupiter's satellites without causing any sensible perturbation of these small bodies. This comet also passed very near the earth; and Laplace calculated that, if its mass had been equal in density to that of the earth, the effect of its attraction would have increased the length of the sidereal year by 2 hours 28 min. But since its influence was altogether insensible, it is certain that its mass was not equal to the five-thousandth part of that of the earth, and was probably much less than even this quantity.

If the real nuclei of comets were solid, the matter of which they are composed must be extremely fixed, in order to enable them to resist the intense heat they necessarily experience in their approaches to the sun. According to the computation of Newton, the great comet of 1680, at its perihelion, was only distant from the sun by the 163d part of the semidiameter of the earth's orbit, where it would be exposed to a heat above 2000 times greater than that of red-hot iron,—a temperature of which we can form no conception, and which would instantly dissipate any substance with which we are acquainted.

The most interesting features of recent research into the subject of comets are (1) the spectroscopic examination of those comets which have appeared since the importance of spectroscopic analysis has been recognised, and (2) the association which has been recognised between meteor-systems and comets.

Periodic comets. Before proceeding, however, to discuss these matters, we give the following tables indicating the progress which has been made in the determination of the orbits of periodic comets:—

Table of Comets having a Mean Distance less than that of Saturn.

Name.	Mean distance from Sun.	Eccentricity.	Inclination.	Period in years.
Encke's..........	2·2181	0·8464	13° 4′ 15″	3·303
Blainpain's......	2·8490	0·6867	9 11 6	4·809
Burckhardt's....	2·9337	0·8640	8 1 45	5·025
Clausen's.........	3·0913	0·7213	1 53 43	5·435
De Vico's........	3·1028	0·6173	2 54 45	5·469
Winnecke's......	3·1343	0·7547	10 48 4	5·549
Brorsen's.........	3·1463	0·7945	30 57 51	5·581

Pons's............	3·1602	0·7552	10 42 48	5·618
D'Arrest's	3·1618	0·6609	13 56 6	6·380
Biela's	3·5306	0·7563	12 33 17	6·635
Faye's	3·8118	0·5576	11 22 7	7·414
Pigott's	4·6496	0·6787	47 43 0	10·025
Peters's..........	6·3206	0·7567	13 2 14	15·990

Motion in all cases direct.

Table of Comets having a Mean Distance exceeding Saturn's, and less than that of Uranus.

Name.	Mean distance.	Eccentricity.	Inclination.	Period in years.
Westphal's......	16·6200	0·9248	40° 53′ 32″	67·770
Pons's	17·0955	0·9545	73 57 3	70·068
De Vico's........	17·5836	0·9544	84 57 13	73·250
Olbers's..........	17·6338	0·9312	44 29 55	74·050
Brorsen's.........	17·7795	0·9726	19 8 25	74·970
Halley's..........	17·9875	0·9674	17 45 5	76·680

Motion of the first five direct, of Halley's retrograde.

Analysis of cometic spectra.

The fine comet of 1858-59, called Donati's, was subjected to a rough spectroscopic analysis by Donati, and the spectrum shown to be discontinuous, consisting of a few broad bands. Comet I., 1866 (called Tempel's), examined by Huggins in 1866, showed three bands in the spectrum of the nucleus. Brorsen's comet, examined in 1868, showed similar appearances. But it was not until the examination of Winnecke's comet in 1868 that any successful attempt was made to compare the band spectrum of a comet's nucleus with the spectrum of a known terrestrial element. The result was somewhat remarkable. It was found that the spectrum is that obtained from carbon when the electric spark is taken through olefiant gas. The same result has been obtained, both by Huggins and by Professors Harkness and Young of America, from the spectroscopic analysis of Encke's comet in 1872. Professor Harkness sums up the result of his own series of researches into the condition of this comet as follows :—(1.) Encke's comet gives a carbon spectrum. (2.) From November 18 to December 2, the wave length of the brightest part of the comet's spectrum was continually increasing. (3.) No polarisation was detected in the light of the comet. (4.) The mass of Encke's comet is certainly not less than that of an asteroid. (5.) There is some probability that the electric currents which give rise to auroras are propagated in a medium which pervades all space, and that the aurora is in reality the spectrum of the medium. 6. It is not improbable that the tails of all large comets will be found to give spectra similar to that of the aurora, though additional lines may be present.

Connection of comets and meteors.

It is only of late years that the study of meteors or falling stars has come to be regarded as belonging to astronomy. Even now the discovery of the connection of meteors and comets is so recent, and the aspect under which the new department of astronomy presents itself varies so continually as fresh relations are recognised, that it seems desirable to limit our remarks to the statement of a few broad facts.

It has been shown, then, that meteors travel in systems round the sun, and that displays of falling stars occur when the earth passes through a meteor-system.

There are already recognised more than one hundred meteor-systems, known by the direction in which the corresponding falling stars encounter the earth.

The best-known meteor-systems are those which produce a shower on November 13–14 in certain years, and those which usually produce a display on August 10–11. The former have been called the Leonides, because the part of the stellar sphere whence the meteors appear to radiate is in the constellation Leo. The latter, for a like reason, appearing to radiate from Perseus, have been called the Perseides.

It has been found that these two meteor-systems accord, so far as their orbital motions are concerned, with two comets, viz., respectively Tempel's comet, I., 1866, and the comet known as III., 1862. The association is indicated in the following table :—

Known Elements.	Orbit of November Meteors.	Comet I. 1866.	Orbit of August Meteors.	Comet III. 1862.
Perihelion passage..........	Nov. 13, 1866	Jan. 11, 1866	July 23·62	Aug. 22·9
Perihelion distance.........	0·9893	0·9765	0·9643	0·9626
Longitude of Perihelion..	...	...	343° 38′	344° 41′
Longitude of Node:........	☋ 51° 28′	51° 26′·1	☊ 138° 16′	137° 27′
Eccentricity ..	0·9033	0·9054	...	...
Semi - axis major........	10·340	10·324	...	...
Inclination....	18° 8′	17° 18′ 1	64° 3′	66° 25′
Period (in years)........	33·25	33·176	...	123·74
Motion	Retrograde	Retrograde	Retrograde	Retrograde

Other comets have been associated, though not quite so distinctly, with meteoric systems. But perhaps the most remarkable evidence in this matter is that afforded by Biela's comet. At the return in 1866, and again in 1872, this comet was not seen; and as it had become divided into two distinct comets in 1846, the inference was, that it had further subdivided since it was last seen in 1852. Now the orbit of this comet nearly intersects that of the earth, at about the place occupied by the earth on November 27. Accordingly, after the fruitless telescopic search for the comet in 1872, Professor Alexander Herschel pointed out that, during the last week in November, meteors following in the train of this comet might be expected to make their appearance. On the night of November 27, 1872, a remarkable shower of meteors was observed, the meteors radiating from a region of the heavens indicating that they were travelling in the track of Biela's comet.

Telescopic observation of comets.

The telescopic study of some of the remarkable comets of the last quarter of a century has been rewarded by results of interest. This has been the case in particular with Donati's comet of the year 1858. During the comet's passage past its perihelion, several envelopes formed around the head, continually passing outwards, and disappearing after a certain distance from the nucleus had been reached, while new envelopes appeared within. Besides the principal tail, which was curved like an aigrette plume, another thin straight tail was visible for a while; and for a short time yet another was seen. A striation of the chief tail could also be recognised, which, according to the researches of Bond and Norton in America, corresponded to the action of a repulsive force exerted by the sun, and sweeping matter away from the main tail with a velocity exceeding that with which this tail itself was formed, but not exceeding the velocity indicated by the straightness of the subsidiary tails.

Coggia's comet.

The great comet of 1874 is shown in fig. 51, as pictured by Mr Huggins. It exhibits well a peculiarity which has characterised many comets, the well-defined dark streak behind the nucleus (which, however, is in this case somewhat eccentrically situated). This phenomenon is not

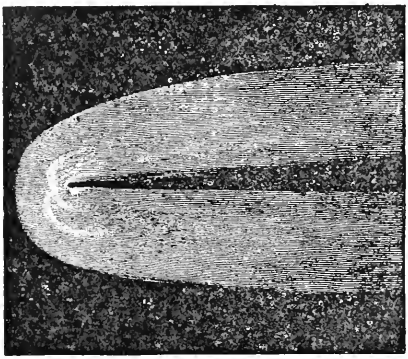

FIG. 51.—Coggia's Comet

easily explained. It is common, indeed, to find it accounted for as due to the absence of illuminated matter behind the nucleus. But as a comet's tail is not a flat object, spread out on the dome of the heavens, but a conical, or rather conoidal, appendage, which viewed from all sides would present, no doubt, much the same appearance, the line of sight directed towards the axis must pass through the illuminated envelope Huggins's spectroscopic examination of this comet yielded results resembling those he had already obtained from small comets. But this was the first comet whose tail he had analysed The spectroscopic analysis of the various parts of the comet gave the following results —

"When the slit of the spectroscope was placed across the nucleus and coma, there was seen in the instrument a broad spectrum, consisting of the same three bright bands exhibited by Comet II., 1868, crossed by a linear continuous spectrum from the light of the nucleus. On the continuous spectrum of the nucleus," he proceeds, "I was not able to distinguish with certainty any dark lines of absorption, or any bright lines, other than the three bright bands. Besides these spectra, there was also present a faint broad continuous spectrum between and beyond the bright bands. When the slit was moved on to different parts of the coma, the bright bands and the faint continuous spectrum were found to vary in relative intensity. When the slit was brought past the nucleus on to the commencement of the tail, the gaseous spectrum became rapidly fainter, until, at a short distance from the nucleus, the continuous spectrum predominated so strongly that the middle band only, which is the brightest, could be detected on it. We have presented to us, therefore, by the light of the comet, three spectra (1) The spectrum of bright bands, (2.) The continuous spectrum of the nucleus; (3.) The continuous spectrum which accompanies the gaseous spectrum in the coma, and which represents almost entirely the light of the tail"

CHAPTER XVIII —*The Fixed Stars and Nebulæ*

The constellations. The great multitude of stars visible even to the naked eye renders it impossible to distinguish each by a particular name, astronomers, accordingly, for the sake of reference, have formed them into groups, known as *Constellations* or *Asterisms* To these the early astronomers gave the names of men and animals, and other objects, from fancied resemblances or analogies, for the most part not easily traced. These denominations are preserved in modern catalogues, and the practice of delineating the object itself on celestial globes and charts has been only recently, if it has yet been altogether abandoned. The ancients distinguished some of the brightest stars in the different constellations by particular names, but to include others less conspicuous, it became necessary to adopt a different mode of proceeding. According to the usual method, first introduced by Bayer in his *Uranometria*, each of the stars in every constellation is marked by a letter of the Greek alphabet, commencing with the most brilliant, which is designated by α, the next most conspicuous is called β, the third γ, and so on. When the Greek letters are exhausted, recourse is had to the Roman or Italic. The order of the letters was intended to indicate only the relative brilliancy of the stars in the same constellation, without any reference to those in other parts of the heavens. Thus α Aquarii is a star of the same order of brightness as γ Virginis. Moreover, whether owing to carelessness in the original lettering or to changes in the brightness of the stars, the order of the letters does not always correspond to the brightness, even in the same constellation. Thus, ϵ, ζ, and η Ursæ Majoris are far brighter than δ of that constellation. The stars of the first order of brightness are likewise denominated stars of the *first magnitude*, those of a degree inferior in brightness are said to be of the *second magnitude*, and so on with the third, fourth, &c. Below the sixth the same denominations are continued, but the stars of the seventh and inferior magnitudes are no longer visible to the naked eye, and are therefore called *telescopic stars*.

The number of constellations given by Ptolemy is 48, viz. —

North of the Zodiac.

1	Ursa Minor,	The Little Bear.
2	Ursa Major,	The Great Bear.
3	Draco,	The Dragon.
4	Cepheus,	Cepheus.
5	Bootes, or Arctophylax,	The Herdsman, or the Bearwarden
6.	Corona Borealis,	The Northern Crown.
7	Hercules ('Εν γόνασιν).	Hercules (kneeling).
8.	Lyra,	The Harp.
9	Cygnus,	The Swan
10.	Cassiopeia.	The Lady in her Chair.
11	Perseus,	Perseus.
12.	Auriga,	The Waggoner.
13.	Serpentarius, or Ophiuchus,	The Serpent-bearer
14	Serpens	The Serpent.
15.	Sagitta,	The Arrow
16	Aquila (or *Vultur*) et Antinous,	The Eagle and Antinous.
17	Delphinus.	The Dolphin.
18	Equuleus,	The Horse's Head.
19	Pegasus, or Equus,	The Flying Horse, or the Horse
20	Andromeda,	Andromeda.
21	Triangulum,	The Triangle.

In the Zodiac.

22.	Aries,	The Ram.
23	Taurus,	The Bull.
24	Gemini,	The Twins.
25	Cancer,	The Crab.
26	Leo,	The Lion, to which Ptolemy joined some stars of Berenice's hair
27	Virgo,	The Virgin.
28	Libra,	The Balence.
29	Scorpio,	The Scorpion
30	Sagittarius,	The Archer
31	Capricornus,	The Goat.
32	Aquarius,	The Water-Bearer
33	Pisces,	The Fishes.

Southern Constellations.

34	Cetus,	The Whale.
35	Orion,	Orion
36	Eridanus, or Fluvius.	Eridanus, or the River.
37	Lepus,	The Hare
38	Canis Major,	The Great Dog.
39	Canis Minor	The Little Dog.
40	Argo Navis,	The Ship Argo.
41	Hydra,	The Hydra.
42.	Crater,	The Cup.
43	Corvus,	The Crow.
44	Centaurus.	The Centaur.
45	Lupus,	The Wolf.
46	Ara,	The Altar
47	Corona Australis,	The Southern Crown
48.	Piscis Australis.	The Southern Fish.

The constellations added by Hevelius are the following (those marked * being now little used) —

*1. Antinous	Antinous
2. Mons Menelai,	Mount Menelaus
3. Canes Venatici,	The Greyhounds
4. Camelopardalis,	The Giraffe
5. Cerberus,	Cerberus
6. Coma Berenices,	Berenice's Hair
7. Lacerta,	The Lizard
8. Lynx,	The Lynx
9. Scutum Sobieskii,	Sobieski's Shield
10. Sextans,	The Sextant
11. Triangulum Australe,	The Southern Triangle
12. Leo Minor,	The Little Lion

The constellations added by Halley in the southern hemisphere are,—

1. Columba Noachi,	Noah's Dove
2. Robur Carolinum,	The Royal Oak.
3. Grus,	The Crane
4. Phœnix,	The Phœnix
5. Pavo,	The Peacock.
6. Apus,	The Bird of Paradise
7. Musca,	The Fly
8. Chamæleon,	The Chameleon.

Distance of the stars.

In considering the fixed stars, the first point to which our attention is naturally directed is the determination of their real dimensions, and a necessary, though not sufficient, preliminary is the determination of their distances from us. An obvious consequence of the annual motion of the earth is the existence of an annual parallax of the stars, but on account of the enormous distances of these bodies, this effect of the earth's motion is so small, that it cannot be easily measured, and there are even now very few cases in which, with the utmost refinements of methods and instruments, a measurable parallax has been detected. We find that, compared with the distances of the fixed stars, the diameter of the earth's orbit is merely a point; for in most cases, the most careful observation of the same star, at intervals of six months, indicates no variation whatever in the star's position, after the proper corrections have been made for the small effects produced by different known causes. The limits of the errors of modern observations cannot well be supposed to exceed 1″ It follows, therefore, that, seen from the distance of the fixed stars, the diameter of the ecliptic, which exceeds 180 millions of miles, subtends an angle of less than 1″ Had the annual parallax exceeded this small quantity, it could scarcely have escaped the multiplied efforts that have been made to detect it; yet the distance of a star having a parallax of 1″ is $\frac{1}{\sin. 1''}$ × radius of earth's orbit, that is, about 19 billions of miles.

The first star actually shown to have an annual parallax was the star 61 Cygni, a binary system of two sixth-magnitude stars, having a large proper motion. The parallax was detected and measured by Bessel, using the Königsberg heliometer. He compared the position of the point midway between the pair with that of two very small and presumably more distant stars. From the observations made between October 1837 and March 1840, Bessel deduced as the parallax 0″·3483, corresponding to a distance of about 600,000 radii of the earth's orbit. This result was confirmed shortly after by Peters at Poulkowa, who, from observations of the zenith distances, deduced the parallax 0″·349. It will presently be seen that more recent measures do not accord well with these results. In the meantime, though the result was published later, Mr Henderson, at the Cape Town Observatory, had been observing α Centauri, one of the brightest of the southern stars, with the object of determining if it has a sensible parallax. Notwithstanding the inferiority of the instrument he employed (a mural circle imperfectly graduated), Mr Henderson succeeded in recognising a parallax, which he estimated at 1″·16. Maclear, who was his successor as astronomer royal at the Cape, determined the parallax to be 0″·9128, and subsequent observations assign to the parallax the value 0″·9187. Doubtless 0″·9 fairly represents the most probable value. It is less than a tenth of the solar parallax; in other words, the orbit of the earth as seen from α Centauri subtends less than a tenth of the arc which the earth's disk subtends as seen from the sun. The distance corresponding to this parallax is in round numbers about 20 billions of miles, a distance which light traverses in about 3½ years.

Other stars have since so far yielded to the attacks made upon them by astronomers as to show signs of having measurable parallax. But it must be admitted that many of the results hitherto obtained are open to considerable doubt, as the following table serves sufficiently to indicate:—

	Magn.	Parallax formerly given by Sir J Herschel.	Latest Measurements of Parallax.
α Centauri.........	1	″0·976 (Henderson, corrected by Maclear)	″0·91
61 Cygni..........	6	0·348 (Bessel)	0·55
Lalande, 21,258 .	8	0·260 (Krüger)........	No new determination
Oeltzen, 17,415-6	9	0·247 (Kruger)	,,
α Lyræ.......... ..	1	0·155 (W Struve, corrected by O. Struve)	,,
Sirius..............	1	0·150 (Henderson, corrected by Peters)	0·27
70 Ophiuchi.......	5	0·160 (Krüger)........	No new determination.
ι Ursæ Majoris ...	3	0·133 (Peters)...........	,,
Arcturus...........	1	0·127 (Peters)......	,,

If we consider that, with the exception of α Centauri, no star has been observed with accordant results, we may question whether the instruments employed by astronomers are as yet competent to measure accurately small parts of a second of arc. As for the parallax assigned to the five last stars of the above list, it would be absurd to place any reliance on the estimated value, save as indicating that those stars lie at so enormous a distance that their parallax cannot be measured.

As the most powerful telescope does not show the real disk of a star, it is not possible to determine by actual measurement the size of even the largest or the nearest. The amount of light received from a star whose distance is known can, however, be compared with that which our sun would give if removed to the star's distance, and if we then assume equal intrinsic surface-lustre, we may infer (though not very safely) the surface, and therefore the size, of the star. Thus the distance of α Centauri exceeds the sun's 230,000 times, so that the sun, removed to the star's distance, would shine with only the 52,900,000,000th part of his observed lustre. But α Centauri shines with about the 16,950,000,000th part of the sun's brightness. Hence the star emits three times as much light as the sun, or (on our assumption) has a surface three times, a diameter $\sqrt{3}$ times, and a volume $3\sqrt{3}$ times (or more than 5 times) as great as his. Sirius dealt with in like manner would appear to have a volume exceeding the sun's about 2700 times But it is probable that the larger stars shine also with a greater intrinsic lustre, mile for mile of surface, and therefore are not so much larger as we should infer from the above method of reasoning.

Analysis of stellar spectra.

That the stars resemble the sun in general constitution and condition has been proved by spectroscopic analysis, the spectra of stars being in general respects like the spectrum of the sun. Nevertheless, characteristic differences exist, insomuch that the stars have been divided into four orders, distinguished by their spectra. These are thus presented by Secchi, after examination of the spectra of more than 500 stars :—

The first type is represented by α Lyræ, Sirius, &c., and includes most of the stars shining with a white light, as Altair, Regulus, Rigel, the stars β, γ, ε, ζ, and η of Ursa Major, &c. These give a spectrum showing all the seven colours, and crossed usually by multitudes of dark lines, but always by the four lines of hydrogen, very dark and strong. The breadth of these lines indicates a very deep absorptive stratum at a high temperature and at great pressure. Nearly half the observed stars showed this spectrum.

The second includes most of the yellow stars, as Capella, Pollux, Arcturus, Aldebaran, α Ursæ Majoris, Procyon, &c. The Fraunhofer lines are well seen in the red and blue, but not so well in the yellow. The resemblance of this spectrum to the sun's suggests that stars of this type resemble the sun closely in physical constitution and condition. About one-third of the observed stars showed this spectrum.

The third type includes Antares, α Orionis, α Herculis, β Pegasi, Mira, and most of the stars shining with a red light. The spectra show bands of lines (Secchi's instrument showed shaded bands, but with superior spectroscopes multitudes of fine lines appear). The spectra resemble somewhat the spectrum of a sun spot, and Secchi infers that these stars are covered in great part by spots like those of the sun. About 100 of the observed stars belong to this type.

The fourth type differs only from the last in the arrangement and appearance of the bands, and includes only faint stars. A few stars, as γ Cassiopeiæ, η Argus, β Lyræ, &c., show the lines of hydrogen bright instead of dark, as though surrounded by hydrogen glowing with a heat more intense than that of the central orb itself.

The exact spectroscopic observation of many stars by Huggins and Miller has shown (what Secchi's comparatively rough observations could not effect) that many elements known to us exist in these stars. Thus, in the spectrum of Aldebaran are lines coinciding with the lines of the elements hydrogen, sodium, magnesium, iron, tellurium, antimony, calcium, bismuth, and mercury. In the spectrum of Betelgeuse these physicists recognised in like manner the lines of sodium, magnesium, iron, bismuth, and calcium, but found the lines of hydrogen wanting. Sirius, Pollux, Castor, the stars of Ursa Major, and many others, were examined with similar results.

Coloured stars. Many stars are coloured. Thus Antares, Aldebaran, and Betelgeuse are ruddy; Arcturus, Procyon, and Pollux yellow; Vega and Altair slightly bluish; while Capella, Sirius, and many other stars are brilliantly white. Among telescopic stars, some are of a deep, almost blood, red, while others are ruddy, orange, yellow, garnet-coloured, and so on. Few single stars show a well-marked blue colour. But among the binary and multiple star-systems, blue, green, indigo, violet, and lilac stars are common, especially as smaller companion stars; such colours as olive, russet, grey, ash-colour, fawn, and so on, are also observed, though this is probably due to the combined lustre of several very small stars closely set. Complementary colours are not uncommon among double stars, the brighter of a pair (in such cases) usually having a red, orange, or yellow colour, and the smaller showing the respective complementary, green, blue, or purple. Nor are these instances to be explained as due to contrast (though contrast doubtless strengthens the apparent hue of the smaller star); for when the brighter is concealed from view, the fainter is still found to shine with its colour unchanged. Spectroscopic analysis shows that usually the colour of a star is due to the presence of absorptive vapours in the star's atmosphere cutting off certain portions of the light. Thus the orange component of the double star Albireo has a spectrum crossed by several bands in the blue and violet portion, while the blue component has a spectrum showing many strong lines in the red and orange portion,—hence the former star looks orange because of the deficiency of blue and violet in its light, and the latter looks blue because its light is deficient in red and orange.

Double and multiple stars. On examining the stars with telescopes of considerable power, many of them are found to be composed of two or more stars placed contiguous to each other, or at distances subtending a very minute angle. This appearance is probably in many cases owing solely to the optical effect of their position relatively to the spectator; for it is evident that two stars will appear contiguous if they are placed nearly in the same line of vision, although their real distance may be immeasurably great. There are, however, many instances in which the angle of position of the two stars varies in such a manner as to indicate a motion of revolution about a common centre; and in this case the two stars form a binary system, performing to each other the office of sun and planet, and connected together by gravity or some equivalent principle. The observations of Herschel, Dawes, South, and Struve have placed this fact beyond doubt. Motions have been detected which are so rapid as to be measurable within very short periods of time; and in certain cases the smaller star has been observed to disappear, either on passing behind or before its primary, or by approaching so near to it that its light has been absorbed by that of the other. The most remarkable instance of a regular revolution of this sort is that of the double star ξ Ursæ Majoris, in which the angular velocity is 6°·4 annually, so that the two stars complete a revolution about one another in the space of 60 years, and about a circuit and a half have been already described since its discovery in 1781. The double star 70 Ophiuchi presents a similar phenomenon, a revolution being completed in a period of about 80 years. α Castoris, γ Virginis, ζ Cancri, ξ Bootis, δ Serpentis, and that remarkable double star 61 Cygni, together with several others, exhibit similar variations in their respective angles of position. Sir W. Herschel observed in all 2400 double stars. The catalogue of Struve of Dorpat contains 3063 of the most remarkable. The object of these catalogues is not merely to fix the place of the star within such limits as will enable it to be easily discovered at any future time, but also to record a description of the appearance, position, and mutual distances of the individual stars composing the system, in order that subsequent observers may have the means of detecting their connected motions, or any changes by which they may be affected. There are many triple, quadruple, and quintuple stars. Every region of the heavens furnishes examples of these curious phenomena; but it is remarked that some parts of the heavens contain very few, while others present them in great abundance.

Star groups. The milky way. Aggregations of stars more and more complex appear as we extend our survey, and wider and wider regions of the heavens are occupied by groups of associated stars. The most complex and extensive of all such gatherings is the galaxy or milky-way, a zone-shaped region surrounding the whole sphere of the heavens, in which stars innumerable so combine their lustre as to present a milky luminosity. We speak of a zone-shaped region, be it noticed, not of a zone, for the milky-way does not form a complete zone, but simply occupies a zone within which appear streams, and nodules, and irregular clusterings of stars. Along part of the region there is but one well-marked stream; elsewhere two streams are seen, and in other places several

But parts of the circuit are incomplete, while in some cases dark regions in the very midst of a bright stream attest the irregular conformation of this strange star region.

Variations of stellar lustre.

Some of the fixed stars are subject to periodical variations of brilliancy. Several, formerly distinguished by their splendour, have entirely disappeared; others are now conspicuous which do not seem to have been visible to the ancient observers, and some alternately appear and disappear, or at least undergo great periodic variations in brightness. Some seem to become gradually more obscure, as δ Ursæ Majoris, others, like β in the Whale, to be increasing in brilliancy. Some stars have all at once blazed forth with great splendour, and, after a gradual diminution of their light, have again become extinct. The most remarkable instance of this sort is that of the star which appeared in 1572, in the time of Tycho. It suddenly shone forth in the constellation Cassiopeia with a splendour exceeding that of stars of the first magnitude, or even Jupiter and Venus at their least distances from the earth, and could be seen with the naked eye on the meridian in full day. Its brilliancy gradually diminished from the time of its first appearance, and at the end of sixteen months it entirely disappeared, and has never been seen since. During the whole time of its apparition, its place in the heavens remained unaltered, and it had no annual parallax, its distance was consequently of the same order as that of the fixed stars. Its colour, however, underwent considerable variations. Tycho describes it as having been at first of a bright white, afterwards of a reddish yellow, like Mars or Aldebaran, and lastly, of a leaden white, like Saturn. Another instance of the same kind was observed in 1604, when a star of the first magnitude suddenly appeared in the right foot of Ophiuchus. It presented phenomena analogous to the former, and disappeared in like manner after some months.

Temporary stars.

Variable stars.

Many stars have been observed whose light seems to undergo a regular periodic increase and diminution, and these are properly called *variable* stars. The star o Ceti (called also Mira) has a period of 334 days, and is remarkable for the magnitude of its variations. From being a star of the second magnitude, it becomes so dim as to be seen with difficulty through powerful telescopes. But its maxima and minima of brightness are variable. Thus between October 1672 and December 1676 Mira was never visible to the naked eye, while on October 5, 1839, it was half a magnitude brighter than its usual maximum.

Some are remarkable for the shortness of the period of their variation.

Algol (β Persei) shines ordinarily as a second magnitude star, but during about 7 hours in each successive period of 69 hours undergoes the following changes:—It decreases gradually to the fourth magnitude, remaining so for 20 minutes, and then increases as gradually to the second magnitude. Thus it remains a second magnitude star for about 62 hours in each period of 69 hours. The star β Lyræ in successive periods of 12 days 22 hours undergoes a double change, each occupying 6 days 11 hours (formerly assigned as the star's true period). In each period the star has a maximum brightness of about the 3·5 magnitude, but the minima of brightness are appreciably unequal, the star's magnitude in one being 4·3, in the other 4·5. The star δ Cephei varies in a period of 5 days 8 hours 48 min. from the fifth to the 3·5 magnitude, occupying 1 day 14 hours in passing from minimum to maximum, but 3 days 19 hours in passing from maximum to mininum. Two or three hundred stars are now recognised as variable. The most probable explanation of the variation in long periods is that stars so affected have periodical maxima and minima of disturbance, resembling that which causes the sun spots, only more marked. Some of the variables of short period are probably covered unequally in different parts of their surface by spots. But the variation of such stars as Algol, which shine with a constant lustre for the greater part of each period, and are reduced in lustre for a short interval, cannot be thus explained, and we must suppose that a large opaque orb circling around them transits the central luminary at regular intervals. Most of the stars which have appeared suddenly, and shone for a short time, probably resemble in character the only star of this kind hitherto examined—the star T in Corona Borealis, which, blazing out suddenly as a second magnitude star (usually of the tenth magnitude only), was found by Huggins and Miller to have a spectrum crossed by fine black lines, on which was superposed the spectrum of glowing hydrogen. As the star waned, the hydrogen spectrum faded, and finally disappeared. Presumably there had been an outburst of glowing hydrogen, or a conflagration in which hydrogen was the principal agent. The maximum brightness of the star exceeded the normal lustre almost 800-fold. The star η Argus can hardly as yet be classed either among periodically variable stars or among stars undergoing irregular changes. In 1677 Halley catalogued it as of the fourth magnitude, Lacaille, in 1751, observed it as of the second magnitude. Between 1811 and 1815 it was of the fourth magnitude, from 1822 to 1826 of the second, in 1827 of the first magnitude, thereafter, till 1837, of the second, in 1838 of the first; in 1843 the star was brighter than any except Sirius. At present it is barely visible to the naked eye.

Irregularly variable stars.

Stellar proper motions.

Passing over the speculations of Bruno, Hooke, and others, we find that Halley was the first to suspect from observation the proper motion of the stars. From comparisons between the observed places of Arcturus, Aldebaran, and Sirius, and the places assigned to these stars by the Alexandrian astronomers, he was led to the opinion that all three are moving towards the south. (*Phil. Trans.*, 1718.) The elder Cassini adopted the same view respecting Arcturus, proving, in fact, that even since the time of Tycho Brahe this star had shifted 5′ in latitude; for he showed that η Bootis, which should have shared in the change if the ecliptic itself had shifted in position, had not changed appreciably in position. Bradley and Wright theorised respecting the causes of stellar motion, and suggested that the sun and his fellow-suns, the stars, are moving in space. Tobias Mayer, in 1771, comparing Roemer's observations in 1706 with his own and Lacaille's in 1750–56, was led to the opinion that the stellar motions afford no sufficient evidence of the translation of the solar system through space. But in 1783 Sir W. Herschel, from the proper motions of seven principal stars, as determined by Maskelyne, deduced as the point towards which the sun is moving (or, as it is now commonly termed, "the apex of the solar way") a point in Hercules in right ascension 257°. After carefully examining Mayer's list of proper motions, he indicated a point close to the star λ Herculis (♅_1, fig. 52). In 1805 Sir W. Herschel published a paper based on Maskelyne's catalogue of the proper motions of 36 stars published in 1790, and presenting a result considerably different from that which he had before announced. He now set the apex in R.A. 245° 52′ 30″ and north declination 49° 38′ (♅_2 in fig. 52). Bessel in 1818 (*Fundamenta Astronomiæ*) expressed the opinion that Mayer had been right in denying the existence of sufficient evidence for determining the proper motion of the solar system. Later, however, the subject has been dealt with by Mädler, Argelander, and O Struve, whose various determinations of the solar apex are shown in fig. 52, marked M, Ar., and Σ_0 respectively. Sir G. Airy re-examined the subject by a new method, assigning to the sun (by an application of the method of least squares) such a direction

Proper motion of the sun

and rate of motion as accounts for the greatest proportion of the observed stellar motions. The plan was carried out

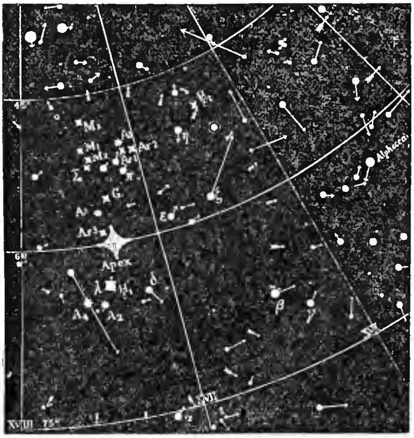

Fig. 52.—Various Determinations of the Apex of the Sun's Way.

according to two different hypotheses respecting errors of observation, and was first applied to about 300 stars, afterwards to about 1500, by Mr Dunkin. The results of the first pair of solutions are indicated by the points A_1 and A_2 in fig. 52, the results of the others by the point A_3 and A_4. A_3 lies in R.A. 261° 14′ and N.P.D. 57° 51′, A_4 in R.A. 263° 44′ and N.P.D. 65°. Lastly, Mr Galloway, by considering the motion of southern stars, has deduced the result indicated at G. Giving to these various results their due weight, we find for the probable position of the apex that shown in fig. 52.

The analysis of the proper motions of the stars by Mr Proctor has led to the recognition of local star-drifts. This is illustrated in fig. 53 Here arrows are drawn from

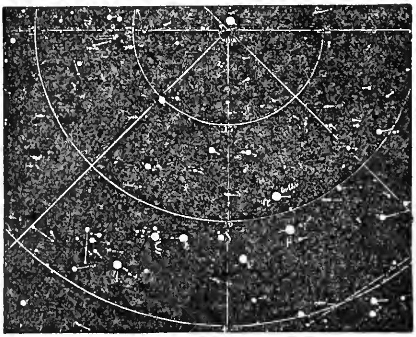

Fig. 53.—Illustrating Star-drift.

the several stars, indicating their direction and rate of motion, the rate being such that 36,000 years would be required to carry any star from its present position to the position marked by the extremity of the arrow-point. It will be seen that the stars β, γ, δ, ε, and ζ Ursæ Majoris, with the companions of ζ are travelling in the same direction and at the same apparent rate. Similar drifting motions can be recognised in other parts of the heavens.

Proper motions of approach and recession. Spectroscopic analysis affords a means of determining the motions of stars in the direction of the line of sight. For if a star is receding, the wave length of any definite portion of its light must be apparently lengthened; while if the star is approaching, such wave-length must be shortened. Thus, if the position of some known line in a star's spectrum can be compared with the position of the same line in the spectrum of a terrestrial element, any shift of position indicates whether the star is receding or approaching. In this way several of the brighter stars have been dealt with by Mr Huggins, and motions of recession and approach, amounting in some cases to 30 or 40 miles per second, have been recognised. This method has afforded an interesting confirmation of Mr Proctor's views about star-drift, seeing that Mr Huggins assigns to the five stars β, γ, δ, ε, and ζ Ursæ Majoris, equal motions of recession (about 17 miles per second). He also finds that their spectra are alike, indicating a resemblance in constitution and structure, such as we should expect to find in the members of a drifting system.

The nebulæ. The *Nebulæ* are celestial objects which present a cloudy appearance. When examined with a telescope of moderate power, the greater part of the nebulæ are distinctly perceived to be composed of clusters of little stars, imperceptible to the naked eye, because, on account of their apparent proximity, the rays of light proceeding from each are blended together, through the effects of irradiation, in such a manner as to produce only a confused luminous appearance. In others, however, no individual stars can be perceived, even through the best telescopes, and the nebula exhibits only the appearance of a self-luminous or phosphorescent patch of matter in a highly dilated or gaseous state. In some instances the nebula presents the appearance of a faint luminous atmosphere, of a circular form and of large extent, surrounding a star of considerable brilliancy. **Orion nebulæ.** One of the most remarkable nebulæ is that which is situated in the sword-handle of Orion. It was discovered by Huyghens in 1656, and described and figured by him in his *Systema Saturnium.* Since that time it has been examined and described by various observers, particularly Fouchy, Mairan, Le Gentil, and Messier, who have given engravings of it; and if any trust can be placed in their descriptions of so indistinct and difficult an object, it must have undergone great changes in its form and physical appearance. Unfortunately, however, no satisfactory inference can be drawn from the comparison of the different descriptions, for it is found that the same nebula, viewed on the same night with different telescopes, presents appearances so different as to be scarcely recognisable as the same object. The effects of atmospherical variations also cause great differences in its appearance, even when it is viewed through the same telescope at different times, so that it is scarcely possible that any two observers will be found to agree in their delineation of its outline. Sir J. Herschel, in the second volume of the *Memoirs of the Astronomical Society*, has given a detailed description of this nebula as it appeared in his twenty-feet reflector in 1824, together with a drawing, which, on account of the superiority of his telescope, is probably a much more correct representation of the object than any which previously existed. Plate XXX. is copied from that drawing. Of that portion of the nebula which he calls the Huyghenian region Sir J. Herschel gives the following account: "I know not how to describe it better than by comparing it to a curdling liquid, or a surface strewed over with flocks of wool, or to the breaking up of a "mackerel" sky when the clouds of which it consists begin to assume a cirrous appearance. It is not very unlike the mottling of the sun's disk, only (if

I may so express myself) the grain is much coarser, and the intervals darker; and the flocculi, instead of being generally round, are drawn into little wisps. They present, however, no appearance of being composed of small stars, and their aspect is altogether different from *resolvable nebulæ*. In the latter we fancy that we see stars, or that could we strain our sight a little more, we should see them, but the former suggest no idea of stars, but rather of something quite distinct from them."

Nebula in Andromeda.

Another very remarkable nebula is that in the girdle of Andromeda, which, being visible to the naked eye, was known in the earliest ages of astronomy. It was rediscovered in 1612 by Simon Marius, who describes it as having the appearance of a candle seen through horn, that is, a diluted light, increasing in density towards a centre. Le Gentil mentions that its figure had appeared to him for many years round, but that in 1757 it had become oval. He also remarks that its light was perfectly uniform in all parts,—a fact which is quite at variance with its present appearance, and which, if true, argues that the nebulous matter is in a rapid state of condensation. "At present," says Sir J. Herschel in the volume above referred to, "it has not, indeed, a star or any well-defined disk in its centre, but the brightness, which increases by regular gradations from the circumference, suddenly acquires a great accession, so as to offer the appearance of a nipple, as it were, in the middle, of very small diameter (10" or 12"), but totally devoid of any distinct outline, so that it is impossible to say precisely where the nucleus ends and the nebula begins. Its nebulosity is of the most perfect milky, absolutely irresolvable kind, without the slightest tendency to that separation into flocculi above described in the nebula of Orion; nor is there any sort of appearance of the smallest star in the centre of the nipple." This nebula has, however, been resolved into stars, at least partially, by the Harvard reflector.

Messier formed a list of 103 nebulæ. But Sir W. Herschel, by means of his large telescopes, discovered no less than 2500, and Sir John Herschel added 500 northern and 1700 southern nebulæ (staying seven years at the Cape to catalogue these last). In all, about 3700 nebulæ are known. They have been thus classified:—

Orders of nebulæ.

(1.) Clusters of stars (globular or irregular) in which the stars are clearly distinguishable.

(2.) Resolvable nebulæ, and such as, from their appearance, probably require only increased power to be resolved into separate stars.

(3.) Nebulæ properly so called, showing no appearance of stars.

(4.) Planetary nebulæ.

(5.) Stellar nebulæ.

(6.) Nebulous stars.

Among the varieties of form may be noted *spiral*, *elliptic* and *ring* nebulæ, *double* nebulæ, and *irregular* nebulæ.

Sir W. Herschel classified the nebulæ according to his conception of the probable stage of their development from purely nebulous matter into stars, single or multiple, as follows:—

(1.) Widely-spread nebulosity.
(2.) Irregular nebulæ.
(3.) Planetary nebulæ.
(4.) Nebulous stars.
(5.) Diffused clusters.
(6.) Stellar nebulæ.
(7.) Rich star-clusters.

Spectra of nebulæ.

Examined with the spectroscope by Mr Huggins, the stellar and resolvable nebulæ are found to give a spectrum resembling the stellar spectrum in general characteristics. But the irregular nebulæ, planetary nebulæ, and a considerable proportion of the irresolvable nebulæ, give a spectrum of three bright lines, indicating that they consist of glowing gas. One of these lines is the F line of the hydrogen spectrum, another is a line of nitrogen, and the third is undetermined. A few of the gaseous nebulæ show a fourth line.

Variable nebulæ.

Some nebulæ are variable. A large irregular nebula surrounding the singular variable star η Argus appears to undergo extensive variations, and we have seen that the great nebula in Orion is strongly suspected of variability. Some nebulæ have vanished, others have appeared where formerly no nebulosity had been recognised.

Groups of nebulæ.

As there are double and variable nebulæ as well as double and variable stars, so also are there groupings and aggregations of nebulæ as of stars. It is noteworthy that the zone region occupied by the milky-way shows very few nebulæ, and those mostly of the resolvable order. The regions farthest from the milky way, that is, the regions around the poles of the galactic circle, are those richest in nebulæ, speaking generally; but the distribution of the nebulæ is in reality too irregular to be sufficiently described in such terms. Streams and branches and clustering aggregations of nebulæ are found in both of the two hemispheres into which the galaxy divides the heavens. Most remarkable among these aggregations are the *Nubeculæ* or *Magellanic Clouds*, in the southern heavens. These resemble the milky-way in aspect, but on telescopic examination are found to consist, not of stars alone, like the milky-way, but of stars mixed with nebulæ. Within the Nubecula Major, Sir J. Herschel counted 278 nebulæ, besides more than 50 outlying nebulæ. The Nubecula Minor is not so rich in nebulæ but still deserves to be regarded as an aggregation of these objects.

Theories of the sidereal universe.

Space will not permit us to consider fully here the various theories of the constitution of the sidereal heavens advanced by Wright, Kant, Lambert, the Herschels, Struve, Mädler, Herbert Spencer, Proctor, and others. But so far as discussion of this subject depends on observation, it may be thus presented:—The zone of the milky-way being rich in stars, we must either infer great extension of the sidereal system in the direction of that zone, or a real aggregation of stars within a ring-shaped or spirally shaped region around the earth. If we adopt the former view, we shall naturally be led to regard the nebulæ, except only those known to be gaseous, as other sidereal systems outside our own, and so distant as to appear like small cloudlets of stars. But if we adopt the latter view, we may regard many of the nebulæ, if not all, as clustering aggregations of stars belonging to the same system. Sir W. Herschel adopted the former hypothesis at the beginning of his career as an observer; but later (though nearly all writers on astronomy overlook the fact), his opinion turned towards the latter. It was while he still supposed the stars spread with tolerable uniformity throughout the sidereal system that he trusted to a method of star gauging depending on the number of stars seen in equal telescopic fields in different directions. It is manifest that, if the telescope reaches to the limits of a system of stars scattered uniformly, the greater the distance at which the limit lies in any direction the greater will be the number of stars in that direction. Gauging the sidereal system on this principle, Sir W. Herschel deduced the inference that it is shaped like a cloven flat disk. But later, perceiving that the rich regions are often seemingly circular in shape, he inferred that such groups are really globular in form. It was natural to extend this principle, and, seeing that parts of the milky way are stream-shaped to infer that this appearance indicates the existence of real streams of stars. Also, since the clustering aggregations are various in size and constitution, it might be assumed that the nebulæ themselves are only clustering aggregations more remote than the rest, and belong, therefore, to the sidereal system. The fact that nebulæ are rich in regions remote from the milky-way would confirm this supposition, if not of itself sufficient (as Herbert Spencer thinks) to establish it beyond question. If the nature of the Magellanic clouds had been known to Sir W Herschel, this inference would have appeared to him irresistible. However, the results towards which his later views seemed tending were not definitely indicated or adopted by him, probably because he had already attained an extreme old age when he first enunciated his later and juster views of the sidereal universe. Sir J Herschel does not appear to have recognised his father's change of views, though conscious of serious difficulties in the older theory, and even definitely indicating the fact that the constitution of the Nubeculæ cannot possibly be reconciled with that theory The elder Struve, probably the only astronomer of his time who had thoroughly *studied* Sir W Herschel's remarkable papers, recognised clearly the change in Herschel's opinions. Following a suggestion thrown out by Piazzi, Struve compared the number of stars down to the eighth magnitude in different directions round the equator, and justly regarded the greater richness of such stars on and near the galaxy as a disproof of Herschel's earlier theory of generally uniform distribution. Strangely enough, however, while thus recognising a variation in the richness of stellar distribution in one direction, *i.e.*, in approaching the medial plane of the galaxy, Struve was unable to divest himself of a belief in uniformity of distribution in directions parallel to that plane. In an investigation claiming to be free from all hypothesis, but in reality (as Encke, Forbes, Proctor, and others have shown) based on several hypotheses, some of which are not even probable, Struve advanced the theory that the sidereal system is infinite in extension along the direction of the medial plane of the galaxy

But in reality the evidence we possess indicates laws of stellar aggregation which by their very nature preclude the possibility of applying such methods of gauging as either Sir W. Herschel or W Struve endeavoured to use. The gathering of stars of the leading orders of *apparent* magnitude in the galactic zone shows that stars of many orders of *real* size and brightness are there gathered together. The analysis of a rich star-region with higher and higher powers is shown to be, not *necessarily*, as was supposed, the penetrating farther and farther into space, but the more and more searching scrutiny of one and the same region of space. The two processes, indeed, may be combined, an increase of telescopic power bringing into view at the same time smaller stars in a particular region and remoter stars lying towards the same direction. In fact, it would be as great a mistake to assume, without definite evidence, that new stars so revealed are smaller in real magnitude, as to assume that they are more remote. The only kind of evidence available to discriminate between the two explanations, or to show to what extent either may operate, is that derived from statistical enumeration, but so complex are the relations involved, that such enumeration can only be interpreted when graphically illustrated. In other words, the secrets of the stellar universe can only be revealed by presenting in well-devised maps the results of widely extended scrutiny of the star depths. This process has already been applied by Mr Proctor to stars down to the eleventh order of magnitude (in the northern heavens), the resulting view of the stellar universe differing widely from that which would have been presented if any of the theories heretofore advanced had been just. It is probable that an extension of the system of uniform star-gauging and charting to the remoter star-depths will still further illustrate the complexity and diversity of structure existing within the universe. Already these general conclusions may be regarded as established:—"The sidereal system is altogether more complicated and more varied in structure than has hitherto been supposed: in the same region of the stellar depths co-exist stars of many orders of real magnitude; all the nebulæ, gaseous or stellar, planetary, ring-formed, elliptical, and spiral, exist within the limits of the sidereal system; and lastly, the whole system is *alive* with movements, the laws of which may one day be recognised, though at present they are too complex to be understood"

Bibliography

Among the most important treatises relating to the history of astronomy may be mentioned Delambre's *Histoire d'Astronomie* (Paris, 1817-21), Narrien's *Origin and Progress of Astronomy*, Lalande's *Bibliographie Astronomique*, Grant's *History of Physical Astronomy* (London, 1852), Bailly's *Histoires de l'Astronomie Ancienne* (Paris, 1781) *et Moderne* (Paris, 1785), Loomis's *History of Astronomy* (New York, 1855), and the *History of Astronomy* in the Library of Useful Knowledge. But the reader desirous of becoming well acquainted with the modern developments of the science will find it necessary to study the papers published by societies specially devoted to astronomy, as well as the astronomical papers published by other scientific bodies. Amongst the proceedings, journals, &c., to be particularly examined are the following:—In Britain—the *Memoirs* and *Monthly Notices* of the Astronomical Society, the *Transactions* and *Proceedings* of the Royal Societies of London, Edinburgh, and Dublin, and the *Reports of the British Association*, in France—the *Comptes Rendus* of the Paris Academy of Sciences; in Germany—the *Abhandlungen* and *Monatsbericht* of the Berlin Academy of Sciences, the *Sitzungsberichte* of the Imperial Academy of Vienna, the *Vierteljahrsschrift* of the *Astronomischen Gesellschaft* (Leipsic), and the *Astronomische Nachrichten* (Kiel); in Russia—the *Bulletins* of the Imperial Academy of Sciences; the proceedings published by learned bodies in Italy, Belgium, Portugal, and Denmark; in America—the *Reports* and *Proceedings* of the Smithsonian Institution (Washington), the *Journal of the Franklin Institute*, *Silliman's Journal*, and the *Proceedings of the American Association*, &c., besides transactions published by various societies in Australia, Canada, and other colonies. The following are among the principal treatises on theoretical and physical astronomy:—The *Principia* of Newton, Laplace's *Exposition du Système du Monde* and *Traité de Mécanique Celeste*, Delambre's *Astronomie Théoretique*, Brunnow's *Spherical Astronomy*, and the fine American works by Watson (of Ann Arbor), Chauvenet, and Loomis. The best works on practical astronomy are Pearson's *Introduction to Practical Astronomy*, the second volume of Chauvenet's work just mentioned (entitled *Spherical and Practical Astronomy*), and Loomis's *Practical Astronomy*. But, with the improvements continually being made in instruments and methods, the best work on practical astronomy soon becomes obsolete unless supplemented by the careful examination of the journals and proceedings mentioned above. For this reason a section on Practical Astronomy has not been added here, as in former editions of this work. Among popular treatises on general astronomy the most trustworthy are Airy's *Ipswich Lectures*, Arago's *Astronomie Populaire* (and the English version by Grant and Smyth), Herschel's *Outlines of Astronomy*, Chambers's *Descriptive Astronomy*, and Guillemin's *The Heavens* (later editions) Among works in special departments of astronomy may be mentioned Nasmyth's treatise *On the Moon*, Secchi's *Le Soleil*, Herschel's *Southern Observations*, Pingré's *Cométographie*, Coulvier-Gravier's *Recherches sur les Etoiles Filantes*, and W Struve's *Etudes d'Astronomie Stellaire*. The principal star atlases are Harding's *Atlas Novus Cœlestis*, Heis's *Atlas* and accompanying *Catalogue*, Bode's *Uranographia*, Argelander's *Uranometria*, and Lubbock's six maps on the Gnomonic Projection, published for the S.D U.K. For many departments of stellar research, however, celestial atlases are insufficient, and star catalogues have to be employed. Among the most important catalogues of isolated stars are Flamsteed's, Bradley's, Piazzi's, Lalande's, Groombridge's *Circumpolar Stars*, the *Catalogue* of the British Association, Argelander's Bonn series (containing 320,000 stars), Bessel's, Weisse's, Main's, &c. Among catalogues of double stars may be mentioned Sir W Herschel's in the *Phil. Transactions*, those by Sir J Herschel and South, and by Sir J. Herschel alone, the lists in the *Monthly Notices of the Astr Society*, and the catalogues of Dembowski, Burnham, P Secchi, Brothers, and others. Schellen's *Spectral Analyse*, or Roscoe's work on *Spectroscopic Analysis*, will be sufficient introduction to the subject of astronomical spectroscopy. In all the departments, however, there are many works besides those named which the student who desires to deal thoroughly with astronomy will do well to examine.

For the construction and use of astronomical instruments see the articles OBSERVATORY SPECTROSCOPE, TELESCOPE, &c. (R. A. P.)

The figures refer to the pages.

ASTRUC, JEAN, a celebrated physician, was born in 1684 at Sauves, in Languedoc. His father, a Protestant clergyman, bestowed great pains upon his early education, after which he studied at the university of Montpellier, where, having commenced the study of medicine, he took his degree as doctor of physic in 1703 In 1706 he lectured at Montpellier as substitute for Professor Chirac. He studied most diligently all medical authors, both ancient and modern, and in 1710 published a treatise on muscular motion, which greatly increased his reputation In that year he was appointed to the chair of anatomy at Toulouse In 1717 he was appointed to teach medicine at Montpellier Subsequently he was appointed successively superintendent of the mineral waters of Languedoc, first physician to the king of Poland, and, in 1731, regius professor of medicine at Paris. Here his lectures on the practice of physic attracted students from other universities, as well as from foreign countries. He prosecuted his studies with unwearied assiduity to an advanced age, and was thus enabled to write many valuable works on medical subjects. He died on the 5th of May 1766, in the 82d year of his age. Of his numerous works, that on which his fame principally rests is the treatise entitled *De Morbis Venereis libri sex*, 1736, 4to. This was afterwards enlarged to 2 vols. 4to, it was translated into French by Jault, 4 vols 12mo, and has been frequently translated into English. In addition to many other works, principally on midwifery and cognate subjects, he published some treatises not connected with medicine, one with the title of *Conjectures sur les Mémoires originaux qui ont servi à Moise pour écrire la Genèse*, Bruxelles (Paris), 1753, 12mo; and two dissertations on the Immateriality, Immortality, and Liberty of the Soul, Paris, 1755. A long analysis of the *Conjectures* is given in the supplement to Herzog's *Real-Encyk d Prot. Theol.*

ASTURIAS, one of the ancient provinces of Spain, formerly (from 1388 downwards) conferred as a principality on the heir-apparent to the throne. By the new division of Spain in 1833, the province took the name of Oviedo, though not to the exclusion, in ordinary usage, of the older designation. It is bounded on the N. by the Bay of Biscay, on the S. by Leon, on the W. by Galicia, and on the E. by Santander, which is now incorporated with Old Castile. It consists of a portion of the northern slope of what is properly a part of the Pyrenean system, and is covered in all directions with offshoots from the main chain, by which it is almost completely shut in on all sides. Only a few of the passes across the mountains are practicable for carriages, and most of them are difficult even for horses. Along the coast there is a narrow strip of level ground, which consists largely of bare and moor-like reaches, covered with furze. The province, as might be supposed, is watered by numerous streams and rivers, which have hollowed out beautiful and picturesque valleys, but owing to the narrowness of the level tract, their courses are short, rapid, and subject to floods. The most important is the Nalon or Pravia, which receives the waters of the Caudal, the Trubia, and the Narcea, and has a course of 62 miles, after it rank the Navia and the Sella. Along the whole extent of the coast, a distance of 130 miles, there is not one good port. In that of Riba de Sella a large frigate may anchor, and Gijon will admit a vessel drawing 16 or 17 feet of water; but the entrance is in both cases difficult and dangerous. The climate of the district is generally mild, but overcharged with humidity, and in the higher regions the winters are protracted and severe. The broken character of the surface prevents anything like extensive agricultural industry, but abundant pasturage is found in the valleys. The wheat crop frequently fails. Rye succeeds better, and is often mixed with the maize which forms the principal food of all but the higher classes. Chestnuts—here, as elsewhere in Spain, an important article of diet—are very abundant on the hills, and the tree supplies valuable timber. Other timber-trees, such as oak and beech, are found in the mountains, along with various medicinal plants, such as hellebore, angelica, and valerian. Apples are abundant, and cider forms the common drink of the people, but little attention is paid to vines. The horses of Asturias are specially gentle and sure-footed, ranking among the best in Spain, and excelling those of Andalusia in strength, though surpassed by them in beauty. Wild deer, boars, and bears are not uncommon among the mountains; and the sea-coasts, as well as the streams, abound with fish of various kinds, including salmon and lampreys, which are sent to the markets of Madrid.

With regard to mineral wealth, Asturias can no longer boast, as it did in the days of the Romans, of satisfying the quest of the "pale seeker after gold," but it possesses valuable coal-measures, which are worked at Langres, Mieres, Santo Firme, &c., and furnish a supply to Cadiz, Carthagena, and other ports in the Mediterranean. The yield in 1868 was 2,720,000-met. quintals, or upwards of 267,000 tons. Beneath the coal-beds there is frequently a large development of hematite or iron ore; copper mines are worked in the neighbourhood of the river Aviles; and lead, magnesia, arsenic, cobalt, lapis lazuli, alum, antimony, jet, marble, and rock-crystal are found in various parts of the province, while amber and coral are gathered along the coast. Fuel of various kinds being plentiful, several manufactories of copper utensils are maintained, which supply some parts of Leon and Castile with kettles, pots, and similar articles. There used, besides, to be a large royal cannon-foundry near Oviedo. Coarse cloth is manufactured in the province, but not in sufficient quantity to supply the inhabitants. The roads in Asturias are not of a very satisfactory description, with the exception of the *Camino real*, or royal highway, leading from Gijon to Leon and Madrid, which was projected by Jovellanos,—himself a native of Gijon,—and cost so much that Charles V. inquired if it were paved with silver. It is carried by means of bridges and embankments over every impediment of a rugged and mountainous territory. A railway has been formed from Gijon to Langres, about twenty-five miles inland, where there are mines; and a more important line uniting Gijon to Leon has for long been "in course of construction."

The capital of the province is Oviedo, and the other towns of importance are Gijon, Aviles, Llanes, and Luarca. Ten miles E.S.E. of Oviedo is the collegial church and sanctuary of Covadonga, famous for its connection with the struggle of Pelayo against the Moors. The people of Asturias have been called the Swiss of Spain: they are robust, patient, and hardy; unenterprising, but laborious, hospitable to strangers, and enthusiastic lovers of their country. Like the Swiss, they leave their homes in large numbers, and make a living in the southern cities as servants and water-carriers, the married women even often hiring themselves as nurses in Madrid and elsewhere. The native dialect is called Bable, and among other distinctive marks employs *f* for the usual Spanish *h* in many words, thus approaching nearer to the original Latin. There is a special clan among the Asturians called the Baqueros, who lead a nomadic life, tending their cattle in winter on the coast, and in summer on the mountains of Leytariegos. They never marry beyond the bounds of the tribe. The ancient Asturians or Astures—so called, it is supposed, from the old Spanish root *ast*, a hill-fortress—were in possession, not only of the present province, but also of what is now the northern part of Leon, where they have left their name to the city of Astorga. The district south of the Cantabrian mountains was subjugated by the Romans

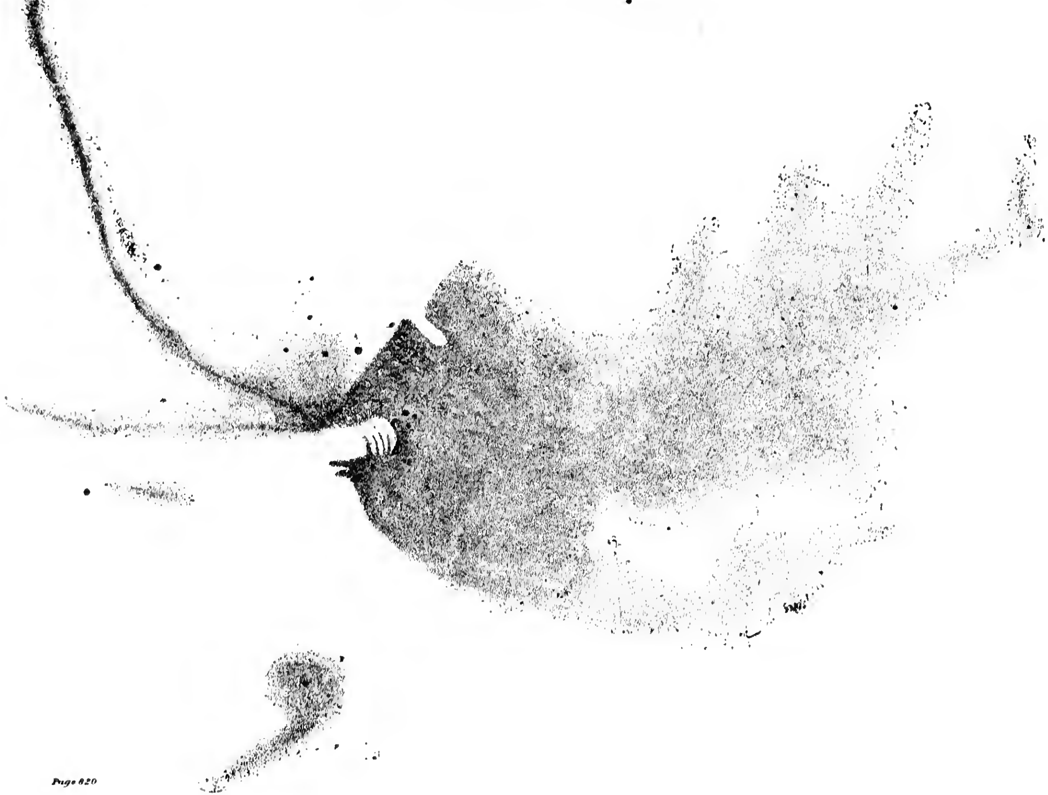
Nebula in the Sword Handle of Orion as seen on the 1st Feby 1824.



Page 820

about 25 B.C., but the warlike natives maintained their independence in the north. And long after, when the rest of Spain was in the hands of the Moors, this rugged region was a refuge to the otherwise vanquished race, which at length acquired strength to break forth from its fastnesses and beat back the invader.

ASUNCION, or ASSUMPTION, the capital of the Republic of Paraguay in South America. It is situated in the midst of a fertile territory on the eastern bank of the River Paraguay (here upwards of 600 yards in width), about 18 miles above the most northerly mouth of the Pilcomayo. It was one of the earlier Spanish settlements in this part of America, being founded in 1535 by Gonzalo de Mendoza and Juan de Salazar y Espinosa, and receiving its name of *Nuestra Señora de la Asuncion*, in honour of the festival of the Assumption. Originally a small fort, it soon became, from the convenience of its situation, a town of considerable importance, and in 1547 was erected into a bishopric. Formerly, while the Jesuits were masters of the country, it consisted of a rather irregular assemblage of one story, houses, relieved by ecclesiastical buildings of varying pretension, from the cathedral downwards; but under the dictatorship of Francia, the streets were more symmetrically arranged, and a number of secular buildings erected. These were greatly increased under the rule of his successors, and Asuncion was brought into similarity with a European city of corresponding rank, having its government house, its president's palace, its arsenal, custom-house, barracks, military hospital, theatre, and railway station. During the recent war between Paraguay and the neighbouring states, Asuncion suffered greatly, being taken and plundered in 1869 by the Brazilian forces, who had already bombarded it from the river. The population, Spanish for the most part in language, but of various races, was estimated, before the war, at 48,000, and carried on a somewhat extensive trade in Paraguay tea, or *Yerba Maté*, hides, tobacco, fruits, molasses, and rum.

ASYLUM (ἄσυλον), in *Greek Antiquities*, a temple enclosure, within which protection from bodily harm was afforded to all who sought it and could prove their danger. In a general sense, all Greek temples and altars were ἄσυλα, that is, it was a religious crime to remove by force any person or thing once under the protection of a deity. But it was only in the case of a small number of temples that this protecting right of a deity was recognised with common consent, and, apparently, these were among the oldest temples of Greece. Such, for example, was the temple of Athena Alea at Tegea in Arcadia, where King Pausanias II. spent the remainder of his days after the battle of Haliartus; or the temple of Ganymeda (Hebe) at Phlius, where, it is said, persons who had escaped from prison hung up their chains in the sacred grove. Other instances are the sanctuaries of Poseidon at Calauria and Tænarum, of Athena Chalciœcus at Sparta, and of Amphiaraus at Oropus; though it is possible, also, with regard to the three last-named sanctuaries, to explain the facts as proving only the ordinary religious *asyla* (Schömann, *Griech. Alterthümer*, ii. p. 202). In Asia Minor these asylums were more numerous and, in Roman times at least, more extensive, so that in the reign of Tiberius the Roman senate considered the question of reducing their limits (Tacitus, *Annal.*, iii. 60, iv. 14). Of these the chief seems to have been that of the temple of Diana at Ephesus, which exercised its right of protection beyond its boundary wall, at one time so far as to include part of the city. But Augustus, finding this an encouragement to crime, reduced the limits (Strabo, p. 641). Even debtors obtained sanctuary at Ephesus. Generally, however, the classes of persons who claimed the rights of asylum were slaves who had been maltreated by their masters, soldiers defeated in battle and pursued by the enemy, and criminals who feared a trial, or who had taken advantage of the opportunity allowed for escape before sentence was passed. A slave was required to show the justice of his complaint, and, if he failed, was restored to his master; if not, a new master was found. In all cases, it seems that the refugee was retained under protection only so long as his means of subsistence lasted, and it may have often happened that pursuit was given up less out of respect for the rights of a temple than from a conviction that want would soon drive the fugitive out of the asylum again. Asylums in this sense were an institution peculiar to the Greeks.—Livy, xxxv. 51, *Templum est Apollonis Delium—ubi et in fano lucoque ea religione et eo jure sancto quo sunt templa quæ asyla Græci appellant.*

ATACAMA, a district of South America, extending along the W. coast from 21° to 25° S. lat., partly belonging to Chili, and partly to Bolivia,—the 24th parallel, according to the treaty of 1866, being recognised as the line of demarcation. (1.) The Chilian province has an area of about 38,000 square miles, with a population of 82,300. It is bounded S. by the province of Coquimbo, W. by the Pacific, and E. by the Argentine Republic. It is one of the richest copper and silver districts in the world, nearly 1000 mines being worked for the former metal, and about 250 for the latter. The silver ore was first discovered in 1832, by a shepherd, Juan Godoy, at a place which has since been occupied by a village that bears his name. The ores of lead and zinc are frequently found, and sulphur, alum, and salt are all of them abundant, the deposit of the last article alone covering about 50 square miles at the Laguna Salada. Gold likewise occurs in sufficient quantity to be mentioned in the list of exports. The capital of the province is Copiapo, with 13,380 inhabitants, and the population is principally clustered in the valleys of Copiapo and Huasco, and in the neighbourhood of the various mines. Caldera is the principal port, and is connected with the capital and the eastern districts by the first railway constructed in South America. The value of the mineral exports through this and the adjacent ports was in 1871 estimated at 6,218,275 dollars. (2.) The Bolivian department has an area of about 70,000 square miles, with a population of about 8000, which is rapidly increasing. It also owes its prosperity almost solely to its wealth in copper and silver. The mines of Caracoles, recently discovered, are said to be the most productive silver mines in the world. In other products it coincides with the Chilian province, with the addition, however, of meteoric iron, which has been found in remarkable masses. A large part of what is more especially designated the Desert of Atacama is included in the department. It is not, as the name might suggest, a sandy, but for the most part a rocky and rugged, tract, with the merest patches and strips of vegetation. The capital of the department is Cobija, or, as it is officially called, Puerto de la Mar; but its prosperity is in some degree threatened by the rise of Mejillones, a seaport which has recently been connected by railway with the principal mining districts. See Philippi, *Reise durch die Wüste Atacama*, Halle, 1860; Tchudi, *Reise durch die Andes*, a supplement to Petermann's *Mittheil.*, 1860; *Journ. Roy. Geog. Soc.* 1851, 1855.

ATAHUALLPA (*atahu*, Latin *virtus*, and *allpa*, sweet), called the last of the Incas, was the son of Huayna Capac, eleventh Inca of Peru, by the daughter of the conquered sovereign of Quito. His brother Huascar succeeded Huayna Capac; for as Atahuallpa was not descended on both sides from the line of Incas, Peruvian law considered him illegitimate. He obtained, however, the kingdom of Quito, whether by stratagem or not is uncertain. A jealous feeling soon sprang up between him and Huascar, who insisted that Quito should be held as a dependent province of his empire. A civil war broke out between the brothers, and, though the details of it are not accurately known, it appears that just about the time when Pizarro was beginning to move inland from the town of San Miguel, Huascar had been defeated and thrown into prison, and Atahuallpa had become Inca. Pizarro set out in September 1532, and made for Cassamarca, where the Inca was. Messengers passed frequently between them, and the Spaniards on their march were hospitably received by the inhabitants. On the 15th November, Pizarro entered Cassamarca, and sent his brother and Fernando de Soto to request an interview with the Inca. On the evening of the next day, Atahuallpa entered the great square of Cassamarca, accompanied by some five or six thousand men, who were either unarmed, or armed only with short clubs and slings concealed under their dresses. Pizarro's artillery and soldiers were planted in readiness in the streets opening off the square. The interview was carried on by the priest Vicente de Valverde, who addressed the Inca through an interpreter. He stated briefly and dogmatically the principal points of the Christian faith and the Roman Catholic policy, and concluded by calling upon Atahuallpa to become a Christian, obey the commands of the Pope, give up the administration of his kingdom, and pay tribute to Charles V., to whom had been granted the conquest of these lands. To this extraordinary harangue, which from its own nature and the faults of the interpreter must have been completely unintelligible, the Inca at first returned a very temperate answer. He pointed out what seemed to him certain difficulties in the Christian religion, and declined to accept as monarch of his dominions this Charles, of whom he knew nothing. He then took a Bible from the priest's hands, and, after looking at it, threw it violently from him, and began a more impassioned speech, in which he exposed the designs of the Spaniards, and upbraided them with the cruelties they had perpetrated. The priest retired, and Pizarro at once gave the signal for attack. The Spaniards rushed out suddenly, and the Peruvians, astonished and defenceless, were cut down in hundreds. Pizarro himself seized the Inca, and in endeavouring to preserve him alive, received, accidentally, on his hand the only wound inflicted that day on a Spaniard. Atahuallpa, thus treacherously captured, offered an enormous sum of money as a ransom, and fulfilled his engagement; but Pizarro still detained him, until the Spaniards should have arrived in sufficient numbers to secure the country. While in captivity, Atahuallpa gave secret orders for the assassination of his brother Huascar, and also endeavoured to raise an army to expel the invaders. His plans were betrayed, and Pizarro at once brought him to trial. He was condemned to death, and, as being an idolater, to death by fire. Atahuallpa, however, professed himself a Christian, received baptism, and his sentence was then altered into death by strangulation. His body was afterwards burned, and the ashes conveyed to Quito. From the reports of the Spanish historians, it is impossible to gain an accurate idea of the character and abilities of the Peruvian monarch, and we have no other notices by which to test their account. (See Prescott's *Conquest of Peru*, and Helps's *Spanish Conquest of America.*)

ATALANTA, in *Greek Legend*, (1) was connected with Arcadia, where, at her birth, she had been exposed on a hill, her father Jasion having expected a son. At first she was suckled by a she-bear, and then saved by huntsmen, among whom she grew up to be skilled with the bow, swift, and fond of the chase, like the virgin goddess Artemis. At the hunt of the Calydonian boar her arrows were the first to hit the monster, for which its head and hide were given her by Meleager. At the funeral games of Pelias, she wrestled with Peleus, and won. Melanion, with intense love, followed, fought, and toiled in her service, she despising love, and remaining true to Artemis long, but yielding at last. She was the mother of Parthenopæus. But there was (2) another Atalanta in Bœotian legends, who was to be obtained in marriage only by him who could outstrip her in a race, the consequence of failure being death. Hippomenes, before starting, had obtained from Aphrodite three golden apples, which at intervals in the race he dropped, and Atalanta, stopping to pick them up, fell behind. Both were happy at the result; but forgetting to thank the goddess for the apples, they were led by her to a religious crime, and for this were transformed into lions (Ovid, *Met.*, x. 560–704). Latterly the adventures of these two separate heroines were united and told as of one.

ATAXY, LOCOMOTOR (*a* priv., τάξις, order—Synonyms, *Progressive locomotor ataxy, Tabes dorsalis, Posterior spinal sclerosis*), a disease of the nervous system, manifesting itself principally by disordered movements of the limbs in locomotion. This disorder is not, as was once supposed, a form of paralysis (there being no diminution of muscular strength), but is dependent on the loss of the power of co-ordinating the muscles into harmonious action, which is essential to the proper performance of the voluntary movements of the body, and the maintenance of its equilibrium. Although the disease had been previously noticed both by Professor Romberg and Dr R. B. Todd, it was first fully described and named by Dr Duchenne in 1858. Its pathology has subsequently been investigated by Mr Lockhart Clarke. Locomotor ataxy usually begins insidiously, and advances slowly. Among the earlier symptoms observed are disorders of vision, with occasionally temporary or permanent paralysis of some of the cranial nerves, a feeling of uneasiness in the back, accompanied with violent shooting pains down the limbs, increased or perverted sensibility in various parts of the body, and disturbance of the genito-urinary functions. These initial symptoms may continue without much change for a long period, but generally in the course of time others are superadded, which give more definite intimation of the existence of the disease, and render its diagnosis a matter of little difficulty. The sufferer begins to be aware that he cannot walk with the same freedom as before, and he feels as if some soft substance were interposed between his feet and the ground. His gait assumes a peculiar and characteristic appearance. He begins the act of walking with evident difficulty, and his steps are short and hurried. Each leg is lifted well from the ground; but as he moves forward it is thrown out from him, and his heel descends forcibly, and is followed at a longer than the normal interval by the sole. In walking he requires the aid of his vision to preserve his equilibrium, and he therefore looks at his feet, or rather at the ground a little in front of them, as he advances. He cannot turn about suddenly without the risk of falling. If asked to stand erect with his feet approximated, and then directed to close his eyes or to look upwards, he immediately begins to sway and totter, and would fall if not supported. These various phenomena are the result, not of any weakness of motor power, but simply of defective muscular co-ordination. Along with this there usually exists markedly diminished tactile and cutaneous sensibility, particularly in the feet and legs. Sometimes the disorder implicates the upper extremities, and then the hands and fingers cease to perform their functions with precision, so that the patient is unable to pick up any small object from the ground, to button or unbutton his clothing, and even sometimes to feed himself, although at the same time there is no weakness in the muscular power of the hand, which is capable of grasping as firmly as before. With the advance of the disease the disorder of movements increases. The patient's efforts to walk become more and more difficult and distressing, for his limbs are jerked about wildly without restraint, while even the aid of his vision and the support of a stick are insufficient to prevent him from falling. Ultimately, all efforts of this kind have to be abandoned, and he is compelled to lie in bed. In the later stages of the disease all the symptoms become aggravated. The shooting pains and violent jerkings of the limbs increase, motor power becomes impaired, and the patient sinks under the prolonged and exhausting course of suffering, or dies from some intercurrent disease. Although usually progressive to a fatal termination, locomotor ataxy is sometimes arrested, and even appears occasionally to be recovered from, particularly in its earlier stages. In most instances its duration extends over a number of years.

The pathological condition giving rise to locomotor ataxy is disease of a certain portion of the spinal cord, viz., the posterior columns and the posterior nerve roots. These undergo various transformations, which result in their ultimately becoming atrophied and indurated. When affecting, as this lesion most commonly does, the lower dorsal and lumbar regions of the cord, the ataxic symptoms are chiefly confined to the legs; but when it affects the cervical portion, the arms are involved. Occasionally the whole posterior columns of the cord are found diseased. The exciting causes of this malady are but ill understood. Exposure to cold and privation, intemperance, over exertion, and mental anxiety have been supposed to give rise to it. In some instances the disease appears to be hereditary. Locomotor ataxy is much more common among men than among women. It is a disease of middle life, being most frequently observed to occur between the ages of 30 and 50. From the nature of the structural changes affecting the spinal cord in locomotor ataxy, it is evident that, beyond the employment of means to alleviate the various painful symptoms, little can be done towards its cure. Numerous medicines have from time to time been brought forward as supposed to possess special efficacy in the treatment of this disease, but none of them have proved to be of much value. The employment of electricity in the form of the continuous current has been recommended by many high authorities. Probably most good will be found to result from careful efforts to maintain the general health by a well-appointed diet and regimen. (J. O. A.)

ATBARA (Bahr-el-Aswad, or Black River), an important river of Eastern Africa. It rises in the mountains of Abyssinia to the N.W. of Lake Tâna, unites its waters with a number of rivers, such as the Settite, the Salaam, the Angarep, and the Tacazze, several of which more than equal it in volume, and continues its northward course till its junction with the Nile at El-Damer. It flows in many parts through a very fertile and beautiful country, tenanted only by the beasts of the field, or sparsely peopled with a few Arab tribes. In the dry season its waters are considerably lessened, but during the rains it has an average depth of 35 or 40 feet, and measures 400 or 500 yards across at its embouchure. See Hassenstein and Petermann's *Karte und Mémoire von Ost-Afrika* (supplement of Petermann's *Mittheil.*, 1861); and Baker's *Journey to Abyssinia* in Jour. Roy. Geog. Soc. 1863.

ATCHAFALAYA (the Lost Water), a river of Louisiana, in North America, or more properly a secondary channel of the Mississippi, by which a portion of its water flows off from the main trunk into the Mexican Gulf. Its mouth is 120 miles W. of the principal embouchure of the Mississippi.

ATE, in *Greek Mythology*, a personification of criminal folly (*Iliad*, xix. 91). She had misled even Zeus to take a hasty oath, when Heracles was born, for which, seeing his folly, he cast her by the hair out of Olympus, whither she did not again return. She fell, it was in later times said, on the hill where Troy was built. Ate, however, remained always a mere allegory, and never assumed the individuality of a goddess, though described (*Iliad*, ix. 502) as a swift-footed being, who leads to crimes which the old and crippled Litæ obtain redrsss for.

ATELLA, an ancient city of Campania, about 9 miles from Naples. In the second Punic war it sided with Hannibal, and, in consequence, its inhabitants were dispersed by the Romans and their place supplied by the people of Nuceria. In the time of Cicero it was a flourishing town, and under Augustus it received a military colony. In the early Christian centuries it was an episcopal see; but in 1030 A.D. its inhabitants were removed to Aversa, the newly founded city of Count Rainulph, and since then it has sunk into ruins. The *Fabulæ Atellanæ* (named after this city) was a species of satirical comedy exhibited at Rome after the subjugation of Campania. The principal characters were Maccus, a fool with ass's ears; Bucco, a loquacious glutton; Pappus, an old simpleton; and Dossenus, a sharper. The comedy was originally in high repute, but was eventually suppressed by order of the senate for indecencies introduced into it.

ATH, or AETH, a city of Belgium, in the province of Hainaut, situated on the river Dender, a navigable confluent of the Schelde, rather more than 30 miles by rail from Brussels. It is well built, and possesses a parish church (St Julian's), dating originally from 1393, and remarkable for the height of its spire; a college, founded in 1416; a town-house, erected about 1600; an orphan asylum, a theatre, &c. The oldest building in the city is the *Tour du Barbant*, which dates from 1150. The population, numbering about 8300, is variously employed in the manufacture of linen, lace, cotton, soap, sugar, salt, beer, gin, dyes, trinkets, &c. Ath was a place of importance in the 13th and 14th centuries, and was afterwards fortified by the Spaniards. It was besieged and captured by Louis XIV. in 1666, restored to the Spaniards in 1679, recaptured by the French under Catinat in 1697, and fortified by Vauban, but again given up by the treaty of Ryswick in the same year. In 1706 it fell into the hands of the allies, but was restored to the empire in 1716. It was captured by the French under Banderon in 1745, and dismantled and restored by Maria Theresa in 1748. Its fortifications were again destroyed in 1781, rebuilt in 1815, and finally demolished in 1830.

ATHABASCA, or ATHAPESCOW, a river in the north-western territory of British North America, which flows into a lake of the same name. It rises in the Rocky Mountains, and has a long and tortuous course in a north-eastern direction, during which it receives the Lesser Slave River, the Red Deer, and several others. The lake is about 230 miles in length, with a breadth varying from 30 to 14 miles, lying in a direction almost E. and W., in lat. 59° N., long. 110° W. It communicates with Hudson's Bay on the one hand, and with the Polar Sea on the other.

ATHALIAH, the daughter of Ahab and wife of Jehoram, king of Judah, who, after the death of King Ahaziah, her son, caused all the male members of the royal house of Judah to be massacred, in order that she might usurp the throne. Among the victims were her own grandchildren, except the youngest, Joash, who was concealed in the temple by his aunt, Jehoshebs, wife of the high priest, Jehoiada. After six years Jehoiada organised a successful revolution in favour of Joash, and caused Athaliah to be put to death by the Levitical guards (2 Kings xi.; 2 Chron. xxii. 10–12, xxiii.) The story of Athaliah forms the subject of one of Racine's best tragedies. It has been musically treated by Handel and Mendelssohn.

ATHANASIUS, St, Bishop of Alexandria, and one of the most illustrious defenders of the Christian faith, was born at Alexandria about the year 297. Of his family, circumstances, or early education nothing can be said to be known, although a legendary story has been preserved by Rufinus of Aquileia as to the manner in which he came, while yet a boy, under the notice of his predecessor, Alexander. It seems certain that Alexander became his patron, took him as a youth into his house, and employed him as his secretary. This was probably about 313, and from this time Athanasius may be said to have been devoted to the Christian ministry. He was, no doubt, a student in the "Didascaleion," or famous "catechetical school" of Alexandria, which included amongst its already illustrious teachers the names of Clement and Origen. In the museum, the ancient seat of the Alexandrian university, he may have learned grammar, logic, and rhetoric. His mind was certainly well disciplined, and accustomed to discuss from an early period the chief questions both in philosophy and religion. The persecution under which the Alexandrian Church suffered at this time, and his intimacy with the great hermit Antony, of which he himself has told us, had all their effect upon his character, and served to nurture in him that undaunted fortitude and high spirit of faith by which he became distinguished.

Before the outbreak of the Arian controversy, which began in 319, Athanasius had made himself known as the author of two essays addressed to a convert from heathenism, one of them entitled *Against the Gentiles,* and the other *On the Incarnation of the Word.* Both are of the nature of apologetical treatises, arguing such questions as monotheism, and the necessity of divine interposition for the salvation of the world , and already in the second may be traced that tone of thought respecting the essential divinity of Christ as the "God-man" for which he afterwards became conspicuous. The origin of the Arian controversy has been already described under the heading Arius. There is no distinct evidence of the connection of Athanasius with the first contentions of Arius and his bishop, which ended in the exile of the former, and his entrance into Palestine under the protection of Eusebius the historian, who was bishop of Cæsarea, and subsequently of his namesake the bishop of Nicomedia. It can hardly be doubted, however, that Athanasius would be a cordial assistant of his friend and patron Alexander, and that the latter was strengthened in his theological position by the young enthusiastic student who had already expounded the nature of the divine Incarnation, and who seems about this time to have become archdeacon of Alexandria. At the Council of Nicæa, in the year 325, he appears prominently in connection with the dispute. He attended the council, not as one of its members (who were properly only bishops or delegates of bishops), but merely as the attendant of Alexander. In this capacity, however, he was apparently allowed to take part in its discussions, for Theodoret (i. 26) states that "he contended earnestly for the apostolic doctrines, and was applauded by their champions, while he earned the hostility of their opponents. Within 'five months' after the return of Alexander to the scene of his episcopal labours he expired, and his friend and archdeacon was chosen to succeed him. He was elected 'in the sight and amidst the acclamations of the people.' He was now about 30 years of age, and is spoken of as remarkable both for his physical and mental characteristics. He was small in stature, but his face was radiant with intelligence, as 'the face of an angel.' This is the expression of Gregory of Nazianzus (*Orat.*, xxii. 9), who has written an elaborate panegyric upon his friend, describing him as fit 'to keep on a level with common-place views, yet also to soar high above the more aspiring,' as accessible to all, slow to anger, quick in sympathy, pleasant in conversation, and still more pleasant in temper, effective alike in discourse and in action, assiduous in devotions, helpful to Christians of every class and age, a theologian with the speculative, a comforter of the afflicted, a staff to the aged, a guide of the young."

The first few years of the episcopate of Athanasius were tranquil , but the storms in which the remainder of his life was passed soon began to gather around him. The Council of Nicæa had settled the creed of Christendom, but had by no means composed the divisions in the church which the Arian controversy had provoked. Arius himself still lived, and his friend Eusebius of Nicomedia rapidly regained influence over the Emperor Constantine. The result of this was a demand made by the emperor that Arius should be re-admitted to communion. Athanasius stood firm, and refused to have any communion with the advocates of a "heresy that was fighting against Christ." Constantine was baffled for the moment ; but many accusers soon rose up against one who was known to be under the frown of imperial displeasure. The archbishop of Alexandria was charged with cruelty, even with sorcery and murder. It was reported that a Meletian bishop in the Thebaid, of the name of Arsenius, had been unlawfully put to death by him. He was easily able to clear himself of such charges, but the hatred of his enemies was not relaxed, and in the summer of 335 he was peremptorily ordered to appear at Tyre, where a council had been summoned to sit in judgment upon his conduct. He did not venture to disobey the imperial order, and a commission was appointed to inquire into an alleged instance of cruelty urged against him, notwithstanding the explanations which he had made. There appeared plainly a predetermination to condemn him, and he fled from Tyre to Constantinople to appeal to the emperor himself. "He resolved," says Gibbon, "to make a bold and dangerous experiment, whether the throne was inaccessible to the voice of truth." He presented himself suddenly with five of his suffragans before the emperor, while riding into his new capital. Refused at first a hearing, his perseverance was at length rewarded by the emperor's consent to his reasonable request—that his accusers should be brought face to face with him in the imperial presence. The leaders of the Tyrian council, amongst the most conspicuous of whom were the two Eusebii, were accordingly summoned to Constantinople, just after they had celebrated, at a great dedication festival at Jerusalem, the condemnation of Athanasius and the restoration of Arius to church communion. In confronting the former before Constantine they did not attempt to repeat the charge of cruelty, but found a more ready and effective weapon to their hands in a new charge of a political kind—that Athanasius had threatened to stop the Alexandrian corn-ships bound for Constantinople. Here, as in other matters, it is very difficult to understand how far there was any truth in the persistent accusations made against the prince-bishop of Alexandria. Probably there was in the very greatness of his character and the extent of his popular influence a certain species of dominance which lent a colour of truth to some of the things said against him. On the present occasion his accusers succeeded in at once arousing the imperial jealousy ; and the consequence was, that, notwithstanding his earnest denial of the act attributed to him, he was banished to Trier, or Treves, the capital of Gaul.

This was the first banishment of Athanasius, which lasted about two years and a half. It was only brought to a close by the death of Constantine, and the accession of Constantine II. as emperor of the West. It is recorded by himself (*Apol.* 7) that, on his return to Alexandria, "the people ran in crowds to see his face, the churches were full of rejoicing; thanksgivings were offered up everywhere; the ministers and clergy thought the day the happiest in their lives." But this period of happiness was destined to be short-lived. His position as patriarch of Alexandria placed him, not under his friend Constantine II., but under Constantius, another son of the elder Constantine, who had succeeded to the throne of the East. He in his turn fell, as his father had done, more and more under the influence of the Nicomedian Eusebius, now transferred to the see of Constantinople. A second expulsion of Athanasius was accordingly resolved upon. The old charges against him were revived, with the addition of his having set at naught the decision of a council. It was further resolved on this occasion to put another bishop in his place. Accordingly, in the beginning of the year 340, a Cappadocian named Gregory, said to be an Arian, was installed by military force on the throne of the great defender of the faith, who, to save his followers from outrage, withdrew to a place of concealment. As soon as it was possible he repaired to Rome, to "lay his case before the church." He was declared innocent at a council held there in 342, and in another held at Sardica some years later. Julius, the bishop of Rome, warmly espoused his cause, and, generally, it may be said that the Western Church was Athanasian in its sympathies and its creed, while the majority of the Eastern bishops sided with the Eusebian party. This severance was clearly shown at the Council of Sardica, where the Orientals refused to meet with the representation of the Western Church, because the latter insisted on recognising the right of Athanasius and his friends to attend the council as regular bishops. The commonly received date of this council is 347, but the rediscovered *Festal Letters* of Athanasius have had the effect of throwing back this date for some years. It has been placed by some as early as the end of 343, by Mansi and others in the end of 344. The decision of the Council of Sardica, however, had no immediate effect in favour of Athanasius. Constantius continued for some time implacable, and the bold action of the Western bishops only incited the Arian party in Alexandria to fresh severities. Gradually, however, the excesses of the Arian party brought their own revenge, while the death of the intruded bishop Gregory, in the beginning of 345, opened up the way for a reconciliation betwixt the Eastern emperor and the banished prelate. The result was the restoration of Athanasius for the second time, amidst the enthusiastic demonstrations of the Alexandrian populace, which is represented by his panegyrist, Gregory Nazianzen, as streaming forth "like another Nile" to meet him in the distance as he approached the city. His restoration is supposed to have taken place, according to the more accurate chronology based upon the *Festal Letters*, in October 346.

For ten years at this time Athanasius held his ground in Alexandria. But the intrigues of the Arian or court party were soon renewed against him, and the feeble emperor, who had protested that he would never again listen to their accusations, was gradually stimulated to new hostilities. A large council was held at Milan in the spring of the year 355, and here, notwithstanding the vigorous opposition of a few faithful men amongst the Western bishops, a renewed condemnation of Athanasius was procured. This was followed up by the banishment of the faithful prelates, even of Hosius of Cordova, whose conciliatory character and intimate connection with the imperial family had not prevented him from addressing to Constantius a pathetic remonstrance against the tyranny of the Arian party. When his friends were thus scattered in exile, their great leader could not long escape, and on the night of the 8th of February 356, while he was engaged in service in the church of St Thomas, a band of armed men burst into the sacred building. He has himself described the scene (*Apol. de fuga*, 24). Here for a time he maintained his composure, and desired the deacon to read the psalm, and the people to respond—"*For His mercy endureth for ever*," and how, as the soldiers rushed forward with fierce shouts towards the altar, he at length made his escape in the crowd, and sought once more a place of safe retirement. The solitudes of Upper Egypt, where numerous monasteries and hermitages had been planted, appear to have been his chief shelter at this time. Here, protected from pursuit, he spent his time in literary labours in behalf of his cause, and to this period, accordingly, belong some of his most important writings, above all the great *Orations, or Discourses against the Arians*, which furnish the best exposition of his theological position and principles.

For six years at this time Athanasius continued in exile, till the death of Constantius in November 361 opened once more the way for his return to his episcopate. Julian, the successor to the imperial throne, professed indifference to the contentions of the church, and granted permission to the bishops exiled in the late reign to return home. Amongst others, Athanasius took advantage of this permission, and seated himself once more upon his throne, amidst the jubilations of the people. He had begun his episcopal labours with renewed ardour, and summoned a council to Alexandria to decide various important questions, when an imperial mandate yet again drove him from his place of power. The faithful gathered around him weeping. "Be of good heart," he said, "it is but a cloud: it will soon pass." His forecast proved true, for within a few months Julian had closed his brief career of Pagan revival, and Athanasius "returned by night to Alexandria." He received a letter from the new emperor, Jovian, praising his Christian fidelity, and encouraging him to resume his work. With the emperor he continued to maintain friendly relations, and even drew out for him a synodal letter embodying the Nicene Creed, which was graciously received. During the brief reign of this bluff soldier-prince, comparative quiet prevailed in the church. But the repose was of short duration. In the spring of 365, after the accession of Valens, troubles reappeared. An order was issued for the expulsion of all bishops who had been expelled by Constantius, and Athanasius was once more forced to take refuge in concealment from his persecutors. His concealment, however, only lasted for four months, when an order came for his return; and from this time (Feb. 366) he was left undisturbed to pursue his episcopal labours. Those labours were unceasing in refuting heretics, in building churches, in rebuking rapacious governors, in comforting faithful bishops, and in strengthening the orthodox everywhere, till at length, in the spring of 373, "in a good old age," he ceased from all his work. Having consecrated one of his presbyters his successor, he died quietly in his own house. His "many struggles," according to his panegyrists, won him "many a crown." He was gathered to his fathers, patriarchs, prophets, apostles, and martyrs, who had contended for the truth. Even those who fail to sympathise with the cause which Athanasius steadfastly maintained, cannot refuse their tribute of admiration to his magnanimous and heroic character. The cynic eloquence of Gibbon grows warm in recounting his adventurous career, and the language of Hooker breaks into stately fervour in celebrating his faith and fortitude. "The whole world against Athanasius, and Athanasius against it, half a hundred of years spent in doubtful trial which of the two in the end should prevail—the side which had all, or else the part which had no friends but God and death—the one a defender of his innocency, the other a finisher of all his troubles." If imperious in temper and inflexible in dogmatic determination, Athanasius had yet a great heart and intellect, enthusiastic in their devotion to Christ, and in work for the good of the church and of mankind.

His chief distinction as a theologian was his zealous advocacy of the essential divinity of Christ as co-equal in substance with the Father. This was the doctrine of the Homoöusion, proclaimed by the Nicene Creed, and elaborately defended by his life and writings. Whether or not Athanasius first suggested the use of this expression, he was its greatest defender; and the catholic doctrine of the Trinity has ever since been more identified with his "immortal" name than with any other in the history of the church and of Christian theology. (For an exposition of the Athanasian Creed, see the article CREEDS.) (J. T.)

ATHELSTAN, or ÆTHELSTAN, son of King Edward the elder, and grandson of Alfred the Great, was born in 895. There has been much doubt with regard to his legitimacy, as his mother, Ecgwyn, is said to have been of humble origin; but these suspicions appear to rest on slight foundations. On the death of Edward in 925, Athelstan, who had been named by him as his successor, was elected king by the Mercians and West Saxons, and crowned at Kingston in Surrey. Considerable opposition was made to his election, and several of the leading nobles entered into a conspiracy to put out his eyes and deprive him of the kingdom. Alfred the Atheling, who himself aimed at the royal power, was suspected of being concerned in this plot, and was obliged to proceed to Rome and there take an oath of innocence. While in the act of swearing at the altar, he is said to have dropped down in a fit, and to have died three days afterwards. In 925 Athelstan gave one of his sisters in marriage to Sihtric, the Danish ruler of Northumbria, on whose death, in the following year, he invaded the Danish dominions, drove out Sihtric's son, Guthfrith, and took possession of his territory. Guthfrith, after an unsuccessful attempt to stir up Constantine, king of Scotland, to whom he had fled and after a fruitless invasion of England, made submission to Athelstan, and was kindly treated by him. During the next few years, the Welsh, both of Wales and of Cornwall, appear to have been subdued, and to have done homage to the king of England, who levied tribute on them, and fixed the Wye and the Tamar as the boundaries of Wales and Cornwall respectively. He was thus virtually king of all England. In 933 or 934 he also invaded Scotland, ravaged all the south country, and compelled Constantine to pay a yearly tribute. Four years later, in 937, a powerful combination was made against him. Anlaf, a Danish chief, or, according to some accounts, a son of Sihtric, with the king of Scotland, the Welsh, and the Danes of the north, invaded England. Athelstan, with his half brother Edmund, met and signally defeated the invaders in the battle of Brunanburh, celebrated in the "Brunanburh War-Song." In 940 or 941 Athelstan died at Gloucester, and was buried at Malmesbury. England had prospered under his reign; for he devoted much attention to commerce, and exercised a fostering care over the civil and religious interests of his people. His power made him respected and esteemed on the Continent, and several foreign princes and nobles were sent to be educated at his court.

ATHENA (Ἀθηνᾶ, Ἀθήνη, Ἀθηναία), in *Greek Mythology*, a goddess who, from being originally a personification of the clear, bright upper region of the sky, had, as early as the time of the epic poets, changed, or advanced, so as to embody under a divine form a conception of the clear insight of the human mind in its various functions. This upper air or ether seemed to be a distinct element in the universe. From it came the light of morning before sunrise and of evening after sunset, reminding us of the light which, in the Mosaic account of the Creation, existed before the sun and moon were placed in the sky. In the first stage of her character, in which, like the other deities of Olympus, she was directly identified with an element of nature and supposed to act as it acted, Athena bore the name of Pallas, and was thought of more in connection with the storms than with the serenity or light of the heavens. The obvious counterpart of a storm was a raging battle, and, accordingly, she became a goddess of war, armed with spear and helmet, and with the *ægis*, or storm-shield, of her father, resistless among men, hurling to the ground the giant Enceladus, and even superior in might to Ares himself, the god of war. The storm sweeps sorest round high citadels, where also the storms of war rage fiercest; and on such places was her favourite abode. But a storm is followed by serenity brighter than before, more enjoyable, and more exciting to activity of every kind; and then the goddess lays aside her armour to encourage and foster skill and industry. Her title is then Ergane. To her was ascribed the invention of spinning and weaving; of taming horses, bridling and yoking them to the war-chariot; of the flute, and in some way of the healing art. This is the second stage of her character, which the myth, agreeably to its principle, explains in a different fashion, when it says that she sprang into existence from the brain of the all-wise ruler of the world, Zeus, and that he had before swallowed his wife, Metis (intelligence). She must therefore have been in a measure a complement of him, created for the purpose of carrying out among men what was in his mind, but what yet he could not himself, as the supreme and impartial ruler, execute. As his substitute, she lent her aid to Heracles in all his hardships and adventures; to Theseus under similar circumstances; to the Greeks in their war against Troy; to Perseus in slaying the Gorgon Medusa, whose head she afterwards bore upon her *ægis*, from which she obtained the name of Gorgophone; and to the Argonauts on their expedition to Colchis. She maintained always her character of a virgin, and, to express this, bore, at Athens in particular, the name of Parthenos. Her birth took place in Olympus, in presence of the other deities, Hephæstus aiding it, as it is coarsely said, by splitting open with his hatchet the skull of Zeus, a subject often represented on the ancient painted vases. This was also the subject of the sculptures in the front pediment of her greatest temple, the Parthenon at Athens. From the fact that in the other pediment the sculptures represented her contest with Poseidon for divine supremacy over Attica, it might perhaps seem that the first act of her existence was to claim this sovereignty. Foremost in her character always is her protection of high citadels, like that of Athens. Yet it was not for this, but for her causing an olive to grow on the bare rock of the Acropolis, that she was chosen rather than Poseidon, whose claim was that he had raised on the same rock a spring of brackish water. The olives of Attica were a source of great wealth, and the light supplied by their oil may have seemed not unlike the light of the ether. As the defender of citadels her title was Polias.

There is, however, a different account of her origin hinging on her name of Tritogenea or Tritonis, and describing her as a daughter of Poseidon and the Triton lake in Libya. But this is obviously a late invention, founded, apparently, on traditions handed down in Libya from the early Minyæ colonists, in whose original seat at Orchomenos and Alalcomenæ in Bœotia was a very early form of the worship of Pallas as a goddess in some way connected with lakes and streams. In this district, in Arcadia, and in Crete also, were found rivers bearing the name of Triton, and associated in very early traditions with the birth of Athena.

At one time, therefore, her relation to or control of the watery element must have formed a considerable part of her worship. To this also is traced her ancient name of Ὄγγα or Ὄγκα at Thebes. How she came by the name of Glaucopis, *i.e.*, "owl-eyed," by which she is so frequently addressed in the *Iliad*, is not satisfactorily explained, least of all by the recent theory, which, interpreting it as "owl-headed," maintains that the goddess had originally the head of an owl, and appeals to certain rude clay vases and figures found on the supposed site of Troy, with faces intended to be human, but yet not much unlike the face of an owl. As the goddess of victory she was called Nike, and it was to her in this capacity that the edifice known as the Temple of the Wingless Victory was erected on the Acropolis of Athens. Hippia was her title as the tamer of horses. Erichthonius, at Athens, was the first mortal whom she taught to yoke horses. For Bellerophon, on the Acropolis of Corinth, she bridled the winged horse Pegasus. Besides Corinth, the chief seats of her worship outside of Attica were Argos, Sicyon, Trœzen (in Arcadia, where, with the title of Alea, warm, fostering, she had a celebrated temple), Laconia, Elis, and in Asia Minor, at Ilium, where it survived after her image, the Palladion, which had fallen from heaven, had been removed to Athens or Argos, both of which claimed to have received it. At Athens an ancient image of her existed in the Erechtheum, and was regarded with peculiar sanctity, even in the times when men were familiar with the splendid statue of her by Phidias in the Parthenon. Except at Athens, little is known of the ceremonies or festivals which attended her worship There we have—(1.) The ceremony of the *Three Sacred Ploughs*, by which the signal for seed-time was given, and, apparently, dating from a period when agriculture was one of the chief occupations of her worshippers; (2.) The *Procharisteria*, at the end of winter, at which all the magistrates offered sacrifice; (3) The *Skirophoria*, with a procession from the Acropolis to the village of Skiron, in the height of summer, the priests who were to offer sacrifice to Athene walking under the shade of parasols held over them, (4.) The *Oschophoria*, at the vintage season, with races among boys, and a procession, with songs in praise of Dionysus and Ariadne, (5) The *Chalkeia*, with rites referring to her as a goddess presiding jointly with Hephæstus over industrial arts, (6.) The *Plynteria* and *Callynteria*, at which the ancient image in the Erechtheum was cleaned, with a procession in which bunches of figs were carried, (7) The *Arrhephoria*, at which four girls, between seven and eleven years of age, selected from noble families, brought during the night certain sacred objects from the temple of Aphrodite by an underground passage to the Acropolis, (8.) The *Panathenæa*, at which the new robes for the image of the goddess were, before being placed on it, carried through the city, spread like a sail on a mast. The last festival was attended by athletic games, open to all who traced their nationality to Athens As to artistic representations of Athena, we have first the rude figure which seems to be a copy of the Palladion, secondly, the still rude, but otherwise more interesting, figures of her, as, *e.g.*, when accompanying heroes, on the early painted vases; and thirdly, the type of her as produced by Phidias, from which little variation appears to have been made. (A. S. M.)

ATHENÆUM, a name originally applied to buildings dedicated to Athena (Minerva), was specially used as the designation of a temple in Athens, where poets and men of learning were accustomed to meet and read their productions. The academy for the promotion of learning which the Emperor Hadrian built at Rome, near the Forum, was also called the Athenæum. Poets and orators still met and discussed there, but regular courses of instruction were given by a staff of professors in rhetoric, jurisprudence, grammar, and philosophy This species of university continued in high repute till the 5th century. The same name was afterwards applied to similar institutions in Lyons and Marseilles; and it has become a very general designation for literary clubs or academies. It has also been used as the title of literary periodicals, particularly of the journal of art criticism edited by the brothers Schlegel, and the two well-known modern papers published in London and Paris.

ATHENÆUS, a Greek rhetorician and grammarian, or man of letters, was a native of Naucratis, a town in Egypt, near the mouth of the Nile. Exceedingly little is known of his life, but from one or two references to known events which occur in his works it may be gathered that he flourished about the end of the 2d and the beginning of the 3d century A.D. Besides a history of the Syrian kings, and a small tract on the identification of the *thratta*, a peculiar kind of fish, mentioned by the comic poet Archippus, both of which are lost, he wrote the extensive work, in fifteen books, called the *Deipnosophistæ*, *i.e.*, the Feast of the Learned, or, as it may be translated, the Skilled in Feasting. The first two books, and parts of the third, eleventh, and fifteenth, are only extant in epitome, but otherwise we seem to possess the work entire. It is an immense store-house of miscellaneous information, largely but not exclusively on matters connected with the table, and full of quotations from writers whose works have not come down to us. It has been calculated that nearly 800 writers and 2500 separate writings are referred to by Athenæus, and he boasts of having read 800 plays of the Middle Comedy alone. Of many writers we have no remains, save the excerpts given by him, and a glance at any collection of Greek fragments will show how large is the proportion drawn solely from this source. The plan of the *Deipnosophistæ* is exceedingly cumbrous, and is badly carried out. It professes to be an account given by the author to his friend Timocrates of a banquet held at the house of Laurentius, a wealthy patron of art. It is thus a dialogue within a dialogue, after the manner of Plato, but a conversation of sufficient length to occupy several days (though represented as taking place in one) could not be conveyed in a style similar to the short conversations of Socrates. Among the twenty-nine guests whose remarks Athenæus reports are Galen and Ulpian, a lawyer, supposed to be the famous jurist. Their conversation ranges from the dishes before them to literary matters of every description, including points of grammar and criticism, and the guests are expected to bring with them extracts from the poets, which are read aloud and discussed at table. The whole is but a clumsy apparatus for displaying the varied and extensive reading of the author. As a work of art it can take but a low rank, but as a repertory of fragments and morsels of information it is invaluable. The text, particularly in the quotations from the minor comic poets, is still in a very corrupt state.

Editions —Casaubon's, 1597, Schweighauser's, 14 vols., with translation and copious commentary, 1801–1807, the best recent editions are Dindorf's, 3 vols., 1827, and Meineke's, 4 vols., 1858–66.

ATHENAGORAS, a Christian apologist, was a native of Athens, and lived during the 2d century A.D. The only sources of information regarding him are a short notice by Philip of Sida, and the inscription on his principal work. Philip says that he was at the head of an Alexandrian school (the catechetical), that he lived in the time of Hadrian and Antoninus, to whom he addressed his *Apology*, and that Clement of Alexandria was his pupil, while Pantænus was the pupil of Clement. This statement is thoroughly inaccurate and worthless. The inscription on the work describes it as the "Embassy of Athenagoras, the Athenian, a philosopher and a Christian, concerning the Christians, to the Emperors Marcus Aurelius Antoninus and Lucius Aurelius Commodus, &c." This statement has given rise to considerable discussion, but from it and internal evidence the date of the *Apology* may be fixed at about 176 or 177 A.D. Athenagoras is also the author of a discourse on the resurrection of the dead, which is not authenticated otherwise than by the titles on the various manuscripts. In the *Apology*, he refutes the accusations brought against the Christians of atheism, eating human flesh, and licentiousness, and in doing so takes occasion to make a vigorous and skilful attack on Pagan polytheism and mythology. The discourse on the resurrection answers objections to the doctrine, and attempts to prove its truth from considerations of God's purpose in the creation of man, His justice, and the nature of man himself Athenagoras is a powerful and clear writer, but his theology is strongly tinged with Platonism. His discussion of the Trinity has some points of speculative interest, but it is not sufficiently worked out; he regards the Son as the Reason or Wisdom of the Father, and the Spirit as a divine effluence. On some other points, as the nature of matter, the immortality of the soul, and the principle of sin, his views are interesting. There are many editions of Athenagoras; the best are those of the Benedictine Maranus, and of Otto, Jena, 1857. The works have been translated into English by Humphreys, London, 1714, and by the Rev. B. P. Pratten, Edinburgh, 1867 (*Ante-Nicene Christian Library*). In 1599 and 1612 appeared in French a work on *True and Perfect Love*, purporting to be a translation from the Greek of Athenagoras; it is a palpable forgery.

ATHENODORUS, surnamed CANANITES or SANDONUS, a Stoic philosopher, was born at Tarsus. He probably gave instruction to Augustus when he was at Apollonia; and on proceeding to the Roman courts, he was made tutor to Tiberius. The emperor esteemed him greatly for his proved virtue and probity. He was in the habit of giving his opinion very freely, and warned Augustus, whenever he found himself giving way to anger, to rehearse the twenty-four letters of the alphabet before saying or doing anything. Retiring late in life to his native town, he died there at the age of 82. None of his works have survived. Another Stoic of this name, surnamed CORDYLION, also of Tarsus, was keeper of the library at Pergamus, and died at Rome in the house of Cato the Younger. There were likewise two sculptors named Athenodorus, one of whom assisted Agesander in the group of the Laocoon.

ATHENRY, a decayed town of Ireland, county of Galway, and province of Connaught, 14 miles E. of Galway. It is a place of antiquity, and traces of its walls and castle, and of an old Dominican monastery, are still visible. It gave the title of baron to the family of De Bermingham, and from the time of Richard II. till the Union it returned two members to parliament. Population of the parish in 1871, 3639.
